The life and prosperity of this nation, as of all civilized European nations, depend, as Bavink has wisely reminded us, on the measures which we are willing to take against the processes which are destroying our racial health. Such measures must of necessity depend upon insight into the causes of the processes. The very stress and strain under which we live to-day forces us back to the Greek ideal of life as a unity, if we are to avoid racial decay and degeneration and social measures which are really anti-social, in promoting the well-being of one set or generation of individuals at the expense of the whole nation and of human civilization. That the present proposals in Great Britain should be submitted by the President of the Board of Education rather than by the Minister of Health is indeed a hopeful sign. It indicates that the Government recognizes not merely the value of physical fitness itself but also the intrinsic relations of mind and body.

If we cannot have a healthy mind without a healthy body, apart from the glaring exceptions of genius to every general rule, or a sane and judicious electorate which has the poison of disease or physical feebleness at work within, equally we cannot have a really healthy body without a healthy mind. The Greek ideal of an active healthy body postulated a corresponding activity of the mind.

Accordingly, the Government scheme wisely recognizes the need for taking account of the many varieties of temperament which may make one man's joy in a particular physical exercise another man's boredom, and refrains from any attempt at a uniform or a compulsory system. To introduce the element of compulsion, in fact, would be to endanger just that willing interest of the mind from which any course of physical training derives half its value. The scheme is thus poles asunder from the compulsory schemes introduced in the totalitarian States, which all too plainly are closely related to military training. The recognition that the best defence of a State is not in walls but in the health, vigour and character of its individual citizens, men and women alike, need no more imply the denial of individuality than it did in ancient Greece. On the contrary, as the scheme rightly insists, it is only as individualism has its sway that the ideal of fitness, whether physical or mental, can be fully realized. Physical and mental well-being is primarily a duty the individual owes to himself and not to the State. He or she best serves the State by realizing the best in himself or herself in a happy balance of mind in which duty is also happiness, liberty makes its own discipline and life becomes an active pleasure instead of a passive existence.

The contribution of the State is accordingly essentially one of co-ordination, the removal of obstacles and the provision of facilities where required. It is important to note that the last by itself may be quite inadequate. Many critics of the scheme who stress the importance of dealing with the questions of malnutrition and housing are not detracting from the value of the present proposals, but emphasizing the necessity of dealing with national health in accordance with a definite co-ordinated plan conceived on wide and generous lines. In such a plan, the Factories Bill at present before Parliament, for example, will find a place, both in respect of its bearing on the employment of juveniles and in the elimination of overtime, industrial disease and other conditions which undermine the health of workers in industry.

It is interesting to note in this connexion two recent precedents for this conception of public health. Recommendations for the prevention of disease recently submitted to the National Health Insurance Committee by the National Physical and Mental Welfare Advisory Board of New Zealand include the suggestion for the replacement of the present Health Department and Mental Hospitals Department by a National Health Department, in which not merely the medical profession but also sciences such as applied biology, chemistry, dentistry, economics, education, ethics, eugenics, hygiene, nutritional physiology, psychology, physics, sociology, etc., are represented in accordance with the principle that the prevention of physical, mental and moral disability and the maintenance of national health require the aid of many branches of science. For this purpose the appointment in each local centre of a man or woman with the synthetic mind, which is not a common characteristic of medical men or other scientific specialists, is recommended.

Even more significant, however, is the system by which the former Social Democratic Municipal Government in Vienna succeeded during its fifteen years rule in changing the population of a town badly shaken by the vicissitudes of a lost war and by the effects of blockade, starvation, poverty and disease into probably the fittest town population of Europe. This welfare and youth protection organization of the Vienna municipality was the best thought out and most efficiently organized single system in the world. Its standard was a good deal higher than any yet known in England, and amounted to a refusal to accept poverty as a reason why any of Vienna's citizens should be unhealthy or lack means for enjoyment.

If the scheme unfortunately no longer exists since the new rulers came to power after February 1934, its details and organization should not be forgotten, above all by scientific workers, whose tradition and responsibility alike it is to urge unceasingly upon the Government the idea of a creative and thinking mind, no less upon national health than in the expenditure of enormous sums on armaments. Not merely from the point of view of the co-ordination of different branches of science in the service of national health, nor from the point of view of securing adequate expenditure on scientific research in this field, whether in physical training itself, in problems of nutrition, housing, industrial disease and safety, but above all from the point of view of the stimulus to intelligence and character which is inherent in a well-conducted scheme, this question of physical training and national health commands the attention of scientific workers. The support which the present scheme may be expected to claim from them, however, should not lead them to overlook the wider and more fundamental questions, or to cease their pressure upon the administration to secure on an ever-increasing scale the free and maximum employment of scientific knowledge and research in the service of the health and welfare of the community.

Nerve, from Amphioxus to Man

The Comparative Anatomy of the Nervous System of Vertebrates, including Man
By Prof. C. U. Ariens Kappers, Prof. G. Carl Huber and Prof. Elizabeth Caroline Crosby. Vol. 1. Pp. xviii+864. Vol. 2. Pp. xii+865–1845. (New York: The Macmillan Co., 1936.) 63*s*. net.

THIS comprehensive work, of nearly 1900 quarto pages carrying more than 700 text-figures, has grown out of Prof. Ariens Kappers' "Comparative Anatomy of the Nervous System", of now more than fifteen years back. The present is a new treatise, retaining however the orientation which Prof. Kappers' earlier treatise had in view. The collaboration of the joint authors has been happy in extending the first-hand touch of the book with current research and research material to both sides of the Atlantic. The Amsterdam Institute of Brain-Research and the Laboratory of Comparative Neurology of the University of Michigan have each supplied their special contributions to the making of the work. But the whole compilation is one harmonious exposition directed throughout to the same main objects, and viewed from a single steady point of view. A bibliography, impressively liberal in scale, is appended to each chapter. The several chapters are themselves of almost monographic proportions, but their scope is always kept broad.

The work may be taken to address, for the most part, readers of two classes. Research workers will assuredly find it indispensable. These it will help to check their own findings and views against a well-balanced presentment of the present state of knowledge. It is exemplary in giving chapter and verse from its authorities. There will further be those who, versed in human anatomy, desire a general background of the neurology of vertebrates against which to set it, giving evolutionary perspective. For these the anatomical side of what they want is provided here better than by any other single work we know. Its volumes will long remain a welcome source of authoritative reference.

The authors begin with an account of the morphology of neurones and of the synapses between them, and the opening chapter includes a presentation of the theory of *neurobiotaxis* as that stands to-day. The theory states that a nerve-cell migrates, or strictly that the body of the nerve-cell shifts, toward a nerve-path from which it is receiving predominant excitation. The topography of nerve-cells in the central nervous organs affords examples of this. Thus associated activity tends to draw two nerve-cells together. Dr. Ariens Kappers will always be remembered in neurology as the earliest observer to put forward as an immediate problem how it is that the several kinds of neurone come by their characteristic individual shape. Most of us were content simply to accept the fact and use it gladly for identifying a cell which did this from a cell which did that, and the shape was clue to the direction of nervous transmission through it. But, as geotropism influences the tree and its branch-pattern, Kappers asked what tropism it might be directs the neurone's branches He discusses this here, and leans towards explanation by galvanotropic processes. It is a subject seeming to beg for experimental observation with the micro-needle of Chambers in embryonic tissue-cultures such as those of the Harrison laboratory.

The work then continues to climb the nervous system stage by stage, and devotes its chapters to successive levels reaching finally the forebrain. Facts and assessments rich in neurological interest are met with as this course is followed. In dealing with the spinal cord, attention is directed to its being in birds actually more primitive than it is in many of the reptiles. Short local paths as against long brain-ward paths are more abundant in the former than in the latter. So voluminous is the group of spinal motoneurones for the pectoral muscle in most birds that it goes by the name of the 'flying centre.' The mammalian spinal cord is as characteristically mammalian as is the mammalian brain. Its brain-ward tracts climb to higher levels of the brain than do their submammalian homologues. Its paths for fine tactile discrimination and muscle-sense are larger than in the submammals and largest of all in man. They are on their way to the great receiving station in the brain, the thalamus, reaching it by relay. Still further marked is this character as followed in downward paths from brain to spinal cord. There are the mid-brain tracts, tecto-spinal and rubro-spinal, the former actually on 'relay' to the viscera as well as skeletal muscle, In addition, a wholly new path descends from the motor field of the brain cortex to the spinal cord to synapse there, via a relay, with the motoneurones of the neck and limbs. This path is in the monkey more than twice as ample as in the dog, and in man as compared with monkey is again far larger still. It typifies the greater grip of the brain cortex on the behavioural acts of man and the greater disablement in man following on cortical injury.

The reviewer has to resist temptation to stay too long over the several fields offered by a detailed and interesting book. Under "Co-ordinating Apparatus" the inferior olive and its 'complex', with their bearings on neck-movement and neo-cerebellum, are very clearly and fully traced. Passing upward, the cerebellum itself is given a penetrative analysis. No part of the brain repays comparative review more worthily; that is allowed it here, and with more than competence. But the problem of how cerebellar symptoms in disease come to be what they are remains still the puzzle it so long has been. It is pointed out that as to cerebellar localization, two disharmonious patterns seem to co-exist, one receptive illustrated by the entrant paths, one mapped out in muscular regions and movements, the two seeming disparate.

Coming to the diencephalon and telencephalon, which are for the non-technical reader what we may suppose he would regard as the brain proper, the account goes forward with its wealth of detail to reach a final chapter of two hundred pages on the cortex in the mammalian brain. It is brought home to us, if need were, that it is to the mammals that life owes this supreme nervous product. We see how the birds, a newer outcome of evolution, are in a sense back-sliders from the path of promise to real progress. They, although starting later, did not follow the lead given by the mammalian stock in making a cerebral cortex. They have developed a brain on another line. They have exalted instinct with its triumphs of performance but its fixities, rather than humble 'trial-and-error' with its adaptability and, despite its humility, its orientations toward 'reason'.

A fully detailed account is given of the remarkable development of the cortex in the mammalian stock up to and into man. Stress is laid on the close correspondence found between the neocortex, which in man is the overwhelmingly larger part of the cortex, and the underlying dorsal thalamus. If we might venture an analogy between the concepts of modern cerebral neurology and the old doctrines of Aristotle's "De Anima" as they echo down the Middle Ages and into the earlier Renaissance, for example with Jean Fernel, it would be to find a likeness between *sensorium commune* and the great complex of the thalamus.

The fields of the cortex which ripen late in the human brain are those which appear late in phylogeny. Some of them were wont to be thought purely cortical in the sense of possessing connexions only with the cortex itself. They are, however, now known to follow what seems indeed a universal rule in being connected with the great subjacent 'exchange', the thalamus, the general receiving station.

The treatise is anatomical, and rightly keeps rather strictly to that scope. Such inferences as it allows itself on function come perhaps with the more impressiveness. It stresses that removal of considerable portions of the total mass of the cortex including the motor fields does not seriously interfere with the normal motor activity of lower mammals such as the rat, yet the destruction of merely a small portion of a certain region of the cortex in man produces a paralysis from which only slight improvement is noted over the course of years. Rats almost completely decorticated are able to learn the brightness discrimination habit in approximately the same time as do normal rats. But in man the destruction by disease of a large area of the cortex commonly brings idiocy.

The human cortex forms the climax, as well it may and indeed must. The preface at the beginning of the first volume had been careful to set forth that, in the descriptions which would follow of the inner urge underlying the development of the brain and nervous system generally, no teleological principle was implied. Each stage of development is an end within itself. "The development is here entelechic," meaning by entelechy an inherent organic property, not a property apart from the organism.

That no reference is made to the difficulty of relating to cerebral structure what is commonly regarded as the greatest of all its functions, mind, is natural enough. Admirable and comprehensive the treatise is; it by those very qualities marks the more definitely the gap between the description of nervous structure and of mind. Nerve and thought, the more we learn about each of them the more different each seems from the other. The more we know about the brain the further it seems to get from mind, because chemistry and physics do not lead there. Matter, however carefully anatomized, does not take us thither. An anatomical treatise may, however, well be excused from raising this question.

The authors are to be congratulated on producing a thoroughly authoritative work, in every way a memorable treatise. That Dean Huber of the University of Michigan did not live to see its completion is a matter of deep regret. Prof. Kappers and Dr. Elizabeth Crosby in their preface pay warm tribute to him as a colleague. The volumes are excellently issued, on paper not too heavy, with liberal type and admirable text-figures, for the most part original to the work. The sole misprint we have noticed is on p. 1663. The whole production with its impressive array of marshalled facts and its clear and judicious exposition is a contribution to its subject for which every neurologist will be grateful.

C. S. S.

Organic Chemistry in Theory and Practice

(1) Essential Principles of Organic Chemistry
By Prof. Charles S. Gibson. Pp. viii + 548. (Cambridge: At the University Press, 1936.) 18*s*. net.

(2) Organic Chemistry:
the Chemistry of the Compounds of Carbon. By Prof. L. J. Desha. (International Chemical Series.) Pp. xv + 750. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 21*s*.

(3) Practical Organic Chemistry:
By Dr. F. G. Mann and Dr. B. C. Saunders. Pp. xiii + 403. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1936.) 8*s*. 6*d*. net.

(4) An Introduction to the Preparation and Identification of Organic Compounds
By Prof. R. D. Coghill and J. M. Sturtevant (International Chemical Series.) Pp. xiii + 226 (New York and London: McGraw-Hill Book Co., Inc., 1936.) 10*s*. 6*d*.

(1) and (2). The chief problem that faces authors of text-books of organic chemistry is that of selection of what is worth while from the vast mass of original literature. In books of moderate size, choice and arrangement of topics are all-important, and the reviewer's task is to consider whether they have been made with proper regard to the theoretical and practical development of the science. In this respect, the authors of both these books may be considered to have succeeded.

The standard is roughly that of a first-year university course, and the books serve as general surveys, which prepare the student for more specialized work. Only where the method is particularly valuable, as in the tautomerism of acetoacetic ester, has a problem been approached from the historical point of view. References are wisely omitted; for here they would only disturb the continuity, and needlessly increase the size. The authors have realized that a text-book of organic chemistry is something different from a suitably abridged version of Beilstein's "Handbuch"; theirs has been a more philosophic approach in which essential principles are emphasized, and in which descriptions of compounds and reactions are presented only in so far as they illustrate them. Thus the subject is taught as a science, and not merely as a technique. The old subdivision into aliphatic and aromatic has been largely abandoned, the grouping being according to function. Aliphatic and aromatic hydrocarbons are treated together, so that the fundamental similarities and differences may be appreciated. Derivatives then follow in their appropriate groups of ketones, acids, amines, etc., with accounts of modern developments appearing in the proper context.

Prof. C. S. Gibson, as befits a teacher at a great hospital, stresses particularly the biological side of the subject. The properties and reactions of biologically important compounds such as lecithin and adrenaline are described at length, and the special value of the book to medical students is enhanced by the full treatment accorded to amino-acids, carbohydrates and purines. A number of representative preparations, and an appendix on practical methods are given. The too frequent use of footnotes is injudicious; for many are too long, and their subjects might well appear in the main text.

Prof. L. J. Desha in particular makes frequent reference to industrial methods, and is alive to the importance of catalytic and high-pressure processes. His book, which is rather wider in scope, includes under the title of "Special Results of Certain Structures" a convincing treatment of such themes as tautomerism, re-arrangements, colour and dyeing. It concludes with a long section on plant and animal products, so that students may have a better knowledge of the "composition of the food they eat, the clothes they wear, and the bodies thus fed and clothed". But even here, Prof. Desha is more concerned with the industrial significance of the products. Special features of his book are the questions at the end of each chapter, and the charts showing the inter-relationships of compounds.

(3) and (4). In his foreword to the first of the two practical books, Sir William Pope reminds us that the "vast superstructure of organic chemical theory" has been based on careful experimental work. It is significant therefore that the four authors confess that the students do not readily link in their minds the 'paper' chemistry of the lecture room, and their own efforts in the laboratory. With this salutary thought, they set out to effect that essential liaison between theory and practice, and they should achieve a large measure of success. Both books may be recommended for the important reason that the authors write from their own experience of large classes, and have borne in mind the cost of materials, the time available, and the convenience of operations. Both pay special attention to safety precautions not only by

prefatorial injunctions, but also by appropriate warnings in the text. Preparations have been carefully chosen, with the view of illustrating reactions and also giving practice in a wide variety of operations. Each is prefaced by a theoretical discussion, and is concluded by an account of the reactions of the product. The modern method of teaching aliphatic and aromatic chemistry together has aided in their selection and arrangement.

The English work is much longer and more comprehensive; in addition to preparations and identification, it deals very fully indeed with quantitative analysis, and has a useful section on practical enzyme chemistry. It is so composed that its earlier pages can introduce the subject in schools, whilst it should prove useful to honours degree students. The very full accounts of practical operations should be of great value in large classes where personal supervision is limited. Every student of organic chemistry will require this extremely low-priced book.

Special emphasis is laid by the American authors on the section dealing with the identification of compounds. They justly point out that a wide experience in practical chemistry, including incidental preparative work, can be gained by it, especially in the important matter of the manipulation of small quantities. They have exercised great care in the preparation of this section, and they claim that their methods, which have been thoroughly tried out at Yale, prove interesting as well as instructive to students. L. P. W.

Evolution of Kingship

Kings and Councillors: an Essay in the Comparative Anatomy of Human Society. By A. M. Hocart. (Egyptian University Collection of Works published by the Faculty of Arts, No. 12.) Pp. 306. (Cairo: Egyptian University; London: Luzac and Co., 1936.) 4*s.* 6*d.*

MR. HOCART has already written an interesting work on the evolution of kingship; and here he deals further with the subject. Starting from the primitive man's desire to control Nature for his own benefit, as expressed in a ritual that mimics or prefigures the fulfilment of his wishes, he finds the prototype of the king in the leader of the ceremonies—the *choregus*, as we may say. Not very explicitly, since he prefers not to enter into the psychology of symbolism, he supposes the protagonist to become somehow identified with his objective, namely, Nature and all that it yields in support of human life; while, by a like process of identification, he is made equivalent to the cult-object as represented by animal, tree, victim, idol and so on. It is explained that "the essential thing in worship is not reverence but identity"; so that killing the king in solemn sacrifice is all in the day's work.

Such identity, it is added, consists in the fact that all alike are "receptacles of the same spirit, life, or whatever you may choose to call it". As owners of the various receptacles, the worshippers are apparently in a position to enjoy to the full this spirit or life at large in the universe, though but at second hand; since it is the splendour of the king that "provides the hard-driven peasant with escape from his drab drudgery"—so much so that, if he realizes that he is but contributing to its upkeep, he will pay his taxes willingly, just as he should in duty welcome the privilege of paying tithes.

Meanwhile, the evolution of kingship would seem in certain respects to have been a degradation in the light of the early notion that a king is meant to reign rather than govern. In place of the undifferentiated quest for life of primitive times which takes concrete shape in the divine king as in an image, the modern world has by specialization narrowed down the aims of the social life as religious *or* civil, rather than as both together; so that in becoming administrative the higher offices of State lose in representative significance. For the rest, we are assured that "we vastly exaggerate the importance of government in our society", seeing that it is self-help that really governs. As for certain recent developments of the political leader, Mr. Hocart must, if he would follow ancient precedent, allow his claim to infallibility, but might likewise insist that an euthanasia goes suitably with that prerogative.

Taken as a whole, this essay is very suggestive, and it will come as a revelation to many that practical politics not only have had a mystical background, but even to-day may depend on the traditional sanctities of life for their subconscious motive. It is a pity that the author goes out of his way to "abjure the method of Tylor and his successors". He has inspiration enough to fill his chapel without pitting himself against the fathers of the church. R. R. M.

An Introduction to Nematology

By B. G. Chitwood and M. B. Chitwood. Section 1, Part 1. Pp. 53. (Baltimore, Md.: Monumental Printing Co., 1937.) 2.50 dollars.

THE Nematode worms, although forming a large class which includes many economically important species, usually receive little attention in zoological text-books. The appearance of a comprehensive account of them in the English language is therefore to be welcomed, and the work, of which this is the first part, will probably contain many surprises for zoologists unfamiliar with the great mass of recent work on the group.

The first chapter contains a semi-popular account of the occurrence, mode of life and economic importance of the Nematodes, and a brief outline of the history of their study. There follows a short summary of their general structure, which might with advantage have been written rather more simply and with fewer technical terms of very recent origin. The next two chapters are devoted to detailed accounts of the cuticle and hypodermis and of the musculature and body-cavity, and will doubtless be followed by chapters on the other organs and systems.

Two "outline classifications" are included, the first containing short definitions of subclasses, orders, suborders and superfamilies, the second still briefer definitions, but extending to subfamilies. The classification adopted embodies advanced views which have not yet stood the test of criticism, and it may be doubted whether the primary division of the class into "Phasmidia" and "Aphasmidia", based on the presence or absence of a pair of small sense-organs on the tail, will prove generally acceptable. The authors' views on taxonomy need not, however, detract from the usefulness of the work.

The text is printed in double columns of rather small type, which some will find a disadvantage, but is profusely illustrated with good figures. A useful feature is the separate bibliography at the end of each chapter or section. H. A. B.

Logging—Transportation:

the Principles and Methods of Log Transportation in the United States and Canada. By Prof. N. C. Brown. Pp. xv+327. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 20*s.* net.

PROBABLY about two million people in North America are dependent on the timber industry. This is at present carried on entirely in virgin forests, though replanting and conservation are safeguarding them for the future. Obviously Nature alone cannot have developed either roads or navigable streams in such parts, and it hence becomes clear that half the cost of board or beam is absorbed in its transport; hence this text-book specialized solely to this one question. The operations after felling are the assemblage of the tree trunks at convenient spots (skidding) and the long-distance transport to the saw mills. Up to the present, the cheapest and most convenient means of transport have been streams and rivers, but these are unsuitable to the heavier hardwoods; and much of the standing timber now lies at higher elevations and remote locations. The question is one of the value of the timber: whether it will pay for the necessary horse or power tractors or chutes to assemble it for water flotation or for rail. The whole book is the story of the engineers' ingenuity in the adaptation of their needs to local topography, and they are the class who will appreciate this admirable and well-illustrated book.

A Manual of Practical Anatomy:

a Guide to the Dissection of the Human Body. By Prof. T. Walmsley. New edition. In 3 Parts. Part 1: The Head and Neck. Pp. viii+357+3 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1936.) 12*s.* 6*d.* net.

THE study of practical anatomy remains, along with instruction in clinical examination, the best of the scientific disciplines to which the medical student is subjected. Each, however, must discard what is redundant, useless or unnecessary, and each must adopt new methods when they are better. In anatomy much useless information has been assembled and taught about the relations of one structure to another. On the other hand, much valuable information about the structure and function of the body has not found its place. For many purposes the X-ray machine is better, more informing and more accurate than the method of dissection.

The present book is shorter than others, and does something to lessen the drudgery of the student. By keeping to illustrations that are simple it remains a dissecting manual, and in furnishing outlines to be filled in by the student it uses a valuable device for learning. The value of the X-ray method of studying anatomy is shown by the reproduction of X-ray films. The skilful use of small print helps the student to evaluate better the information he is acquiring.

This useful and straightforward dissecting manual is a contribution towards a more satisfactory presentation of the anatomy of the human body.

A History of Fishes

By J. R. Norman. Second edition. Pp. xv+463+8 plates. (London: Ernest Benn, Ltd., 1936.) 15*s.* net.

FIRST published in 1931, this book is by now sufficiently well known and appreciated to render a lengthy review unnecessary. A veritable encyclopædia on fish-life, profusely illustrated by Lieut.-Col. W. P. C. Tenison, it is a most interesting and useful volume which most specialists and many laymen would like to have on their bookshelves. Hitherto, the published price of 28*s.* net has prevented this, but the recent issue of a photo-lithographic reproduction of the original work, at the much more favourable price of 15*s.*, will enable many more to purchase a copy. Comparing this second edition with the first, it must be admitted that the print has lost quality in the process of reproduction, although the general result is surprisingly good. The binding, however, would seem to leave something to be desired, since the plates (at least in the reviewer's copy) will soon become detached, including the most attractive photograph of the angel fish which forms the frontispiece.

Meteorites and the Craters on the Moon

By Dr. L. J. Spencer, C.B.E., F.R.S.

SEVERAL views have, from time to time, been put forward to explain the origin of the remarkable series of shallow craters on the surface of the moon. One of these is that they were formed by the impact of meteorites. Two main objections to this view have been frequently stated. It is said that all meteorites would not have fallen in a direction perpendicular to the surface to produce craters of a circular outline : many must have fallen obliquely and formed oval craters. Again, it is often asked : Why is the earth's surface not pock-marked in the same fashion ? A study of meteorite craters and of meteoritic showers[1] on the earth's surface shows that both these objections are without justification.

Since the discovery of the meteorite craters at Henbury in Central Australia[2] in 1931 and at Wabar in Arabia[3] in 1932, it has been clearly demonstrated that these are not craters of impact or percussion, but that they are explosion craters. The kinetic energy of a large mass of iron (nickel-iron) travelling at a high velocity, was suddenly transformed into heat, vaporizing a large part of the meteorite and some of the earth's crust, so producing a violent gaseous explosion, which formed the crater and back-fired the remnants of the meteorite. Such an explosion crater will be circular in outline whatever be the angle of approach of the projectile. The materials collected at the Wabar craters afford the clearest evidence that very high temperatures prevailed. The desert sand was not only melted, yielding a silica-glass, but this boiled (b.p. about 3,500°C.) and was vaporized. The meteoritic iron was also in large part vaporized, afterwards condensing as a fine drizzle. Minute spheres of nickel-iron, of the same composition as the meteorite, are preserved in the bubbly silica-glass. In some portions these are present to the extent of about two million per cubic centimetre of the glass. The fact that these minute spheres show a bright and highly polished surface suggests that the earth's atmosphere was blown aside in the fiery blast.

On the earth's surface, only five really certain examples of meteorite craters are yet known. These are all associated with fragments of meteoritic iron. Stony meteorites have not been found around any crater, despite the fact that, of observed meteoritic falls, 95 per cent are stones. Irons form only 5 per cent of observed falls ; but they account for 82 per cent of 'finds' of which the fall is not recorded. The friable stony meteorites are usually broken up in the earth's atmosphere, and fall as a shower of stones. Only a really large mass of iron can possibly give rise to a crater. Near the largest known iron meteorite, the Hoba in South-West Africa, weighing 60 tons (or 100 tons allowing for the surrounding zone of iron-shale), there is no sign of a crater.

Astronomers, who revel in large numbers, tell us that some twenty million meteors enter the earth's atmosphere every day. The majority of these are assumed to be the size of a pea or a grain of sand. But perhaps they may be much larger, for the ablation of material from the surface of a meteor must be enormous. In any event, those that reach the earth's surface must have been very much reduced in size ; and the number actually collected each year averages only five. We have to be thankful that our atmosphere extends for at least a hundred miles above the earth's surface.

On the moon, with the absence of an atmosphere, conditions are very different. Meteorites there will encounter no check on their velocity. They will not be reduced in size, and stony masses will not be broken up. They will strike the surface at 20 or 40 or more miles per second. An astronomically small body with a radius of 100 feet and consisting of nickel-iron with a density of 7·7 will have a mass of very nearly a million tons and a kinetic energy measured by $\frac{1}{2}mv^2$. When this is arrested, something is going to happen. Part of the energy will be expended in penetrating and compressing the materials on the surface of the moon. This pressure will be released with explosive violence and moonquake waves will result. But a large part of the energy will be transformed into heat, vaporizing the meteorite and adjacent materials, and causing a violent gaseous explosion.

The idea of such a gaseous explosion was anticipated before the discovery of the Henbury and Wabar craters in a remarkable paper which has only now come to my notice and which appears to have been generally overlooked. In 1924, A. C. Gifford[4] compared the craters on the moon with the Arizona crater, and he concluded that they are explosion craters. The energy of a meteorite travelling at 20 miles per second he calculated to be 123,900 calories per gram, and at 40 miles per second to be 494,700 cal./gm.; compared with the energy of dynamite of about 1,100 cal./gm. He assumed that the meteorite would penetrate to a depth of two miles in the moon's crust (but this is surely too deep), and calculations for various velocities (0·01–0·32 miles per second) of the ejected materials gave for the resulting craters diameters of 0·197–202 miles across the rim. He further showed that a central peak will be formed inside the crater, and that the amount of material ejected may be fifty or sixty thousand times the mass of the meteorite.

S. Mohorovičić[5] in 1928 also concluded that the lunar craters are explosion craters, but he attributed them to explosive volcanic action. By exploding charges buried in cement powder, he produced craters with a striking resemblance to those on the moon, some of which show the central peak and the outer radial streaks. Similar craters were also produced by Alfred Wegener[6] by throwing spoonfuls of cement powder on to a level surface of the same material; and he concluded that the lunar craters were formed merely by the impact of meteorites. Robert Hooke in his "Micrographia" (London, 1665, p. 243) compared the craters on the moon with those formed by the "eruption of vapours" on the surface of "a pot of boyling Alabaster", and with those formed by dropping bullets on to wet "Tobacco-pipe clay". He rejected the analogy of impact, for, as he naively remarks, "it would be difficult to imagine whence those bodies should come." In his day, reports of the fall of stones from the sky were discredited by scientific men. These experimental craters are shallow saucer-shaped depressions with a steep inner slope at the rim and a gentle slope outside, just as is seen in meteorite craters. Larger artificial craters of the same kind are formed by high-explosive shells and military mines.

The bright streaks radiating for hundreds of miles from some moon craters, for example, Tycho and Copernicus, but casting no shadows and conspicuous only at full moon, present a difficult problem. These craters may perhaps be due to the fall of large meteoritic irons, the density of which is 7·7, as compared with 3·5 of stones. The vaporized metal probably condensed as millions of tiny spheres, as at Wabar. (An astronomical calculation will give the number of such spheres, 0·01 mm. in diameter, that could be produced from, say, a million tons of metal!) The force of gravity on the moon being only one sixth of that on earth and there being no air resistance, such particles might be projected for great distances by the explosion. Experimental explosion craters show rays of material beyond the crater rim; Mohorovičić obtained rays a metre in length outside a crater 3·6 cm. in diameter. It may be suggested that these bright streaks on the moon are areas covered by tiny spheres of shining metal. Some support to this view is given by the fact that the ratio of the number of craters showing bright rays and spots to those without these features is of the same order as the ratio of the numbers of irons and stones that reach the earth. Craters that show no bright rays and spots can then be supposed to have been formed by the fall of stony meteorites.

The darker areas or 'seas' of the moon show fewer craters, and some of those around the borders are broken. These areas perhaps represent lava-fields of more basic lava from fissure eruptions, comparable with the plateau basalts of the Brito-Arctic region, the Columbia River in the western United States, and the Deccan in India. (The density of basalt, 2·8—3·1, is less than that of the moon as a whole, 3·3.) Such areas must be of later date than the broken craters and the surrounding mountains; but earlier than the fewer perfect craters within the areas, and also earlier than the bright streaks running across them from craters outside. The mountains are no doubt the result of crustal movements following shrinkage; and are earlier than the lava-fields. The several craters evidently belong to different periods. Some were no doubt formed when the moon first had a solid crust. Except when engulfed by lava-fields, these features will persist, for, in the absence of water and an atmosphere, there can be no denudation, as takes place on the earth. The effects of insolation and desert weathering must, however, be particularly severe—a point that does not seem to have been realized. With the sudden changes in temperature from the very hot day to the very cold night, each with a duration of half a lunar month, rocks will be exfoliated and crystals cracked along their cleavages, and all materials on the surface will be reduced to a fine powder.

On the earth, the few known meteorite craters are of recent formation, though none within the historic period. The same is true of the fall of the eleven known larger masses of meteoritic iron, ranging from the Hoba of 60 tons to the Cranbourne of 3½ tons in the British Museum collection. These will be destroyed by weathering and all traces of them obliterated by denudation long before the next geological period. Fossil meteorites are not known; nor is there any probability of any ever being found. The argument based on the absence of pitting on the earth's surface could never have come from a geologist.

Considered as volcanoes, the lunar craters can be compared only with explosion craters.

None of them shows a cone reaching as high as the outer rim. Further, these cones are usually craterless, and more of the nature of a central peak. In nearly all the craters the rim is complete. In the few good examples of terrestrial volcanic explosion craters, formed by the blowing away of the cone of a typical volcano, the rim is always broken. The Monte Somma rim extends only half-way round the new Vesuvius, and the rim of Krakatoa is very irregular. The quiescent type of the Hawaiian volcanoes have craters of irregular outline. Photographs of a model of Vesuvius and the volcanoes of the Phlegrean Fields have been given to show an apparent similarity to the lunar craters; but the photographs, being taken in plan, are misleading, for these volcanoes are actually cones rather than depressed craters. Terrestrial volcanoes are distributed along lines of weakness in the earth's crust; whereas the craters on the moon are scattered about promiscuously, as if from a pepper-pot.

A point that perhaps invalidates the meteorite theory is that there is no evidence of the formation of craters on the moon at the present time. An apparent variation in the size and brightness of the small crater mapped as Linné affords the only doubtful evidence of any change. Nevertheless, meteorites are still falling on the earth, in spite of the protecting atmosphere; and presumably they must also be falling on the moon. In earlier periods it is evident that the meteoritic bombardment must have been much more intense. Maybe the larger stray masses of the solar system have already been gathered up. On the earth during historic times there has been no catastrophic fall, except perhaps that on June 30, 1908, at a spot in central Siberia, almost as inaccessible to us as the moon itself, and of which precise information is still lacking.

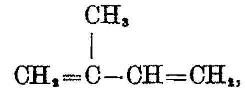
Pigments Associated with the Fatty Tissues of Plants and Animals*

By Prof. I. M. Heilbron, F.R.S., and A. E. Gillam

TURNING now to a brief consideration of the question of the biogenesis of the carotenoids, their structure reveals an obvious connexion with isoprene



$$CH_2{=}\overset{\overset{\displaystyle CH_3}{|}}{C}{-}CH{=}CH_2,$$

a hydrocarbon that may be regarded as the fundamental unit from which numerous important plant products are elaborated, as a result of the regular combination of individual units. The fact that the carotenoids are symmetrical necessitates, however, the assumption that they are built up in the plant, not on this simple plan alone, but by the union of two molecules of an intermediate compound containing twenty carbon atoms. According to Karrer, this may be the alcohol phytol, $C_{20}H_{39}OH$, which constitutes approximately one third of the chlorophyll molecule. Condensation of two phytyl residues could thus theoretically give rise to lycopene from which, by simple ring closure, the carotenes would be produced.

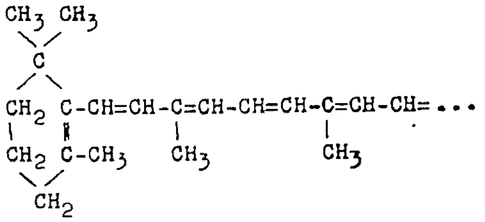
In conclusion, the physiological importance of these pigments in the economy of life must be considered. So early as 1919, Steenbock advanced evidence of a possible connexion between carotene and vitamin A, the physiologically important substance found in all liver oils, notably those of the cod and halibut. This is essential for growth, for in its absence young animals cease to grow, and ultimately die. More specific effects due to vitamin A deficiency are the eye disease, xerophthalmia, decreased resistance to respiratory infections and night-blindness. This latter affection is completely curable in a few days by the absorption of food rich in vitamin A; its cause appears to be related to the fact observed by Wald that the vitamin plays an essential role in the visual perception which occurs on the retina of the eye. The vitamin itself forms an almost colourless highly viscous oil which is notable for its intense absorption band at 328 mμ, and the characteristic blue colour which it gives with antimony trichloride. It is thus clear that the pigment carotene cannot itself be vitamin A, but, as established by von Euler in 1929, it can nevertheless replace the typical vitamin in the animal organism. Complete clarification of this apparent anomaly was reached when Moore conclusively

* *Continued from p.* 615.

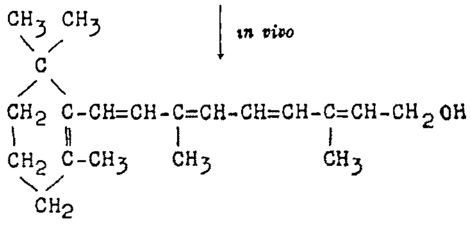
demonstrated that if carotene is fed to rats suffering from vitamin A deficiency, it is converted into the colourless vitamin, which appears in the liver.

The structure of vitamin A has been established, and its formation from carotene may be represented by the following equation, although the exact mechanism of conversion is still obscure:

$$C_{40}H_{56} + 2H_2O = 2C_{20}H_{30}O$$



½ β-Carotene



Vitamin A

Arising from the foregoing, it follows that animals are primarily dependent upon the carotene of grass for their supply of vitamin A. The full appreciation of this fact opens up interesting problems for mankind, and much experimental work is being carried out in order to make use of this new knowledge.

Of the many studies which have been made of the variations in the carotene and vitamin A content of milk as affected by the diet, breed, age, etc., of the cows, I need only mention a few carried out notably by Steenbock in America, by Messrs. Imperial Chemical Industries, Ltd., at their experimental farm in Berkshire, as well as in our own laboratory.

Palmer and Eccles were the first to prove that the yellow colour of butter is mainly due to carotene. The further discovery that butter also contains vitamin A and that the two pigments can be quantitatively evaluated by spectroscopic methods opened the way to the investigation of the factors controlling the quantities of these substances in milk and butter. The actual amounts normally present in milk fat are extremely small, namely, carotene 1–20 parts and vitamin A 2–20 parts per million. In collaboration with Prof. J. C. Drummond of University College, London, Dr. R. A. Morton of Liverpool University, and Dr. S. J. Watson of I.C.I. Agricultural Research Station, we have, during the past few years, been examining the possibility of maintaining the high vitamin content of summer milk throughout the winter. We have ascertained that by employing grass, artificially dried in specially designed driers, in place of part of the concentrates usually given to stall-fed cattle in the winter, both the vitamin A and carotene content of milk (and hence of butter) can be maintained at nearly the level usually regarded as peculiar to summer samples. In a particular experiment, one group of Shorthorn cows was stall-fed on a normal diet throughout a whole winter, whilst another group had a dried grass supplement replacing part of the concentrates. Vitamin A and carotene were determined in the milk fats once a month and the results, expressed graphically in Figs. 1 and 2, leave no doubt as to the efficacy of the dried grass supplement.

Similar experiments have been carried out with A.I.V. silage instead of dried grass. This particular silage is made by storing the fresh grass in a silo and conserving it by sprinkling with dilute acid, the process being due to A. I. Virtanen of Finland.

The following results are typical of those obtained with this fodder. A group of thirteen pure-bred South Devon cows were stall-fed for five weeks on an ordinary winter ration of hay and concentrates. They were then placed on a diet containing 40 lb. of A.I.V. silage per cow per day for five weeks, and afterwards transferred back to the control ration for another five weeks. The colour, carotene, and vitamin A values of the resulting butters are shown in Table 4 and clearly demonstrate—from the vitamin A angle—the value of A.I.V. silage.

TABLE 4

EFFECT OF A.I.V. SILAGE IN THE RATION, ON COLOUR, CAROTENE AND VITAMIN A CONTENT OF MILK FAT (SOUTH DEVON COWS)

	Ration	Date of sample	Yellow Colour (Lovibond units)	Carotene (mgm. % fat)	Vitamin A (mgm. % fat)
1st Period	Control 5 weeks	Jan. 25, 1933	4·0	0·10	0·18
2nd ”	A.I.V. silage 5 weeks	March 1, 1933	8·4	0·27	0·41
3rd ”	Control 5 weeks	April 7, 1933	2·8	0·11	0·24

Although the vitamin A activity of a butter can in general be roughly correlated with its yellow colour, we have found that this is only strictly true when comparing butters from the same breed of cow. Thus when Shorthorn or Ayrshire cows were fed on a ration rich in carotene, the yellow colour rose to a maximum above which the further addition of carotene in the diet would not increase it. The Shorthorn butter was, however, always somewhat more yellow than that obtained from the Ayrshire cows. The traditionally high yellow colour of the milk in Jersey and Guernsey cattle is due to their having a higher 'ceiling value' for carotene in their milk-fat than any of the other breeds Experimental results indicate, however, that although Shorthorn milk-fat is normally paler than that from the Guernsey cow, the gross vitamin A activity is about the same; this is due to the fact that the milk of the Shorthorn has a slightly higher proportion of the true vitamin A.

The figures in Table 5 were obtained by spectrophotometric examination of the milk fats of pure-bred Shorthorn and Guernsey cows kept on the same diet at the National Institute for Research in Dairying. Parallel biological tests for gross vitamin A potency carried out by Dr. S. K. Kon showed that the butters of the two breeds were indistinguishable at each of the three seasons.

The differences in carotene and vitamin A content of the milk of different species of animals are exemplified by the Guernsey cow and the goat; for the latter, in striking contrast to the former, gives a butter which is almost dead-white in colour. Despite the almost total absence of carotenoids in goat's butter, it nevertheless contains vitamin A in amount only slightly lower than that of an average cow's butter.

Although the seasonal variations in the colour and vitamin A content of milk and butter are actually directly due to the presence or absence of carotene in the diet, that is, fresh green grass is necessary to produce good yellow butter, there is one exception to this generalization. Whatever the breed of cow or the season of the year, the colostrum is usually 10–20 times richer in both vitamin A and carotene than is the normal milk. The quality falls rapidly from the first day after calving and reaches normality again in about a week. This richness in vitamin A is therefore quite consistent with the traditional belief in the high food value of colostrum, and furnishes another remarkable example of the way in which biological processes provide for special circumstances in the life of the organism. These phenomena have been shown to be exactly parallelled in the human subject.

Examples of the relative vitamin A values of ordinary and colostrum milk are given in Table 6, the results having been obtained in the course of the experiments described above.

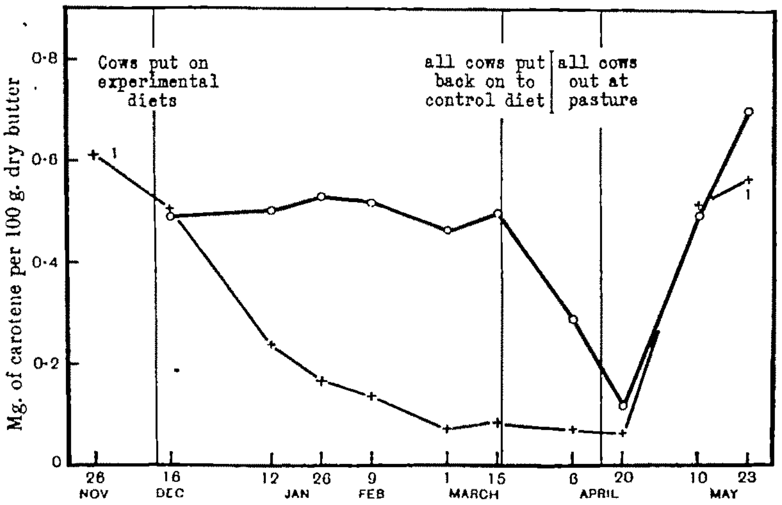


Fig. 1. CAROTENE OF THE BUTTERS
+ — +, control ration. o — o, artificially dried grass ration.

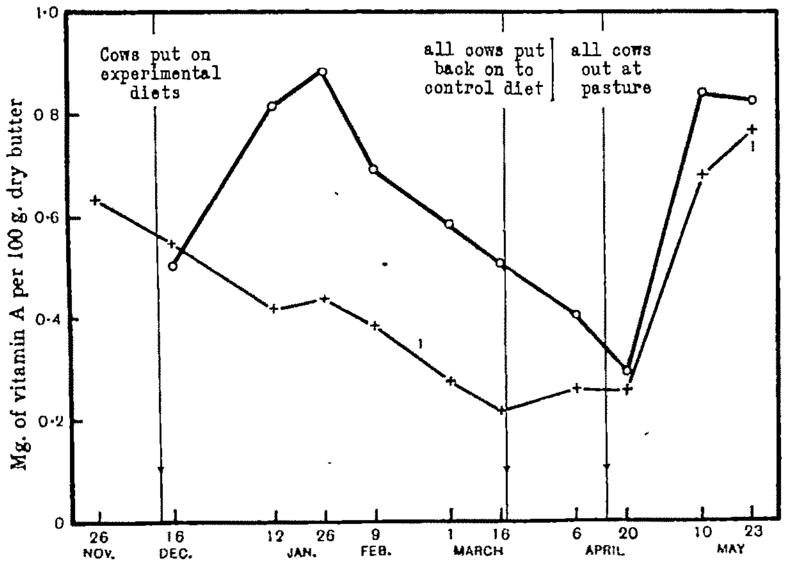

Fig. 2. VITAMIN A* OF THE BUTTERS
+ — +, control ration. o — o, artificially dried grass ration.

Examination of the carotene and vitamin A values of milk-fat leads to a consideration of the vehicle by which the carotene of the food is transported to the udder of the cow, namely, the blood serum. Studies of bovine blood sera have shown that the carotene and vitamin A vary with the amount of carotene in the food, thus being richer in summer than in winter. It is also interesting to note that the serum of cows is distinctly richer than is that of bulls, but whether this is due to a genuine sex difference or to different conditions of management has yet to be ascertained (cf. Table 7 due to Gillam and El Ridi).

---

* Results expressed here and throughout this article are based on the assumption that pure vitamin A has an intensity of absorption of $E^{1\%}_{1\text{cm.}}$ 328 mμ = 1600.

TABLE 5

CAROTENE AND VITAMIN A VALUES OF SHORTHORN AND GUERNSEY BUTTER FATS UNDER IDENTICAL CONDITIONS OF FEEDING

	Shorthorn		Guernsey	
	Carotene	Vitamin A	Carotene	Vitamin A
Summer	0·78	1·10	2·24	0·89
Autumn	0·67	0·93	1·80	0·70
Winter	0·19	0·39	0·50	0·34

(Values as mgm. per 100 gm. fat).

TABLE 6

COMPARISON OF THE CAROTENE AND VITAMIN A VALUES OF THE FAT OF ORDINARY AND COLOSTRUM MILK (INDIVIDUAL COWS CHOSEN AT RANDOM)

Breed	Date of sample	Carotene (mgm. % fat)	Vitamin A (mgm. % fat)
Friesian	Oct. 20	3·40	1·24
	Nov 20	0·38	0·52
Ayrshire	Nov. 22	4·60	2·96
	Dec. 22	0·18	0·37
Guernsey	Oct. 28	3·61	1·13
	Nov. 28	0·91	0·67
Shorthorn	Oct. 13	2·90	3·51
	Nov. 13	0·28	0·48

TABLE 7

CAROTENE AND VITAMIN A IN COW'S BLOOD SERA (AVERAGE VALUES)

	Cows		Bulls	
	Carotene	Vitamin A	Carotene	Vitamin A
Winter	0·40	0·13	0·08	0·05
Summer	1·11	0·29	0·42	0·14

(All values as mgm. per 100 ml of serum)

We have attempted in the foregoing to trace the stages in the development of our knowledge of the lipochrome pigments and to show how, by the application of the elegant methods now used by the organic chemist, the constitution of the more important of these natural polyenes has been elucidated. Apart from the intrinsic interest of this work, it has led to the fundamental discovery of the close interrelation between carotene and vitamin A, one of the indispensable key substances of life.

Fire-Walking: Scientific Tests

EIGHTEEN months ago, the University of London Council for Psychical Investigation arranged a demonstration of fire-walking, with the view of obtaining precise information upon its scientific aspects. Descriptions of the condition of the feet of the performer, Kuda Bux, before and after the walk, and results of some physical observations, were given in NATURE of September 21 and 28, 1935 (136, 468, 521). As the observations were not altogether conclusive, two more demonstrations were arranged by the University of London Council for Psychical Investigation through Mr. Harry Price, honorary secretary of the Council, in the grounds of Mr. Alex. Dribbell at Carshalton, Surrey, on April 8 and 10.

The professional fire-walker was Ahmed Hussain, a Moslem from Cawnpore. In the first experiment, the trench containing the charcoal on oak-ash was 12 ft. long. The temperatures were measured by special thermocouples with the co-operation of the Cambridge Scientific Instrument Co., Ltd., and were shown to be 575° C. on the surface and 700° C. inside. After examination and tests for chemical treatment, Hussain walked the trench in 1·3 sec., showing no signs of injury. He then repeated the walk leading three amateur volunteers with the claim that they would be immune from burning. They were, however, all burned to a varying but slight degree. A further two volunteers then performed the walk separately and unaided. They were also slightly burned, and where the number of steps had been uneven, the foot that had been down most often was most affected. This indicated that the injurious effect was cumulative, although Hussain claimed that he could walk any distance. As he refused to retrace his steps, the trench was increased to 20 ft. for the second experiment.

In the second experiment, the surface temperature was 740° C. and the inside 750° C. Hussain took six steps in 2·3 sec., and this produced five blisters on one foot and marked erythema on the other, a condition closely resembling that of the amateurs after four steps. The effect was therefore cumulative in his case also. One of the former volunteers covered the distance in four steps and 1·4 sec., and then later, in rope-soled shoes, took seven steps in 3·6 sec. The frayed portions of the rope were slightly scorched at the edges only. The feet sank into the ash to a depth of between two and three inches, and it seems clear that its poor thermal conductivity prevents damage to normal skin if the contact-time is less than about half a second, although the small flames within it will produce singeing of the hairs. This time corresponds with that of one quick step: two steps with the same foot could only be done without injury by the practised professional, and three steps was beyond his limit.

This small difference between amateur and professional, together with observations made during the experiment, make it very unlikely that any hypothesis of a special induced mental state is required, such as is, of course, maintained by the Indian performers.

Obituary Notices

Prof. A. Pictet

THROUGH the death, on March 12, of Amé Pictet, Swiss chemists have lost their doyen, and organic chemistry one of its foremost investigators. Descended from a family of bankers, Pictet was born at Geneva on July 12, 1857, and in 1876 he entered the local university. In deciding to devote himself to scientific investigation, he followed a Swiss patrician tradition which has given us, to name but a few, De Saussure the physicist and De Candolle the botanist, both citizens of Geneva, the Bernouilli brothers and the two cousins Sarasin, respectively mathematicians and oceanographers of Basle. After some years of study at Geneva under Marignac, Pictet migrated to Dresden, then to Bonn, where he attended Kekulé's lectures and wrote a doctor's dissertation on the esters of tartaric acid, under the direction of Anschütz. After further study in Paris, he returned to Geneva and became in 1882 *Privatdozent*, in 1894 extraordinary professor of organic chemistry, in 1897 ordinary professor of biological and pharmaceutical chemistry, and ultimately professor of inorganic chemistry.

Pictet's early work on heterocyclic compounds, such as phenyl indole, phenanthridine and isoquinoline was connected with his interest in alkaloids, dating from the time of his doctor's dissertation, and showing itself more fully in his book "Constitution chimique des alcaloïdes végétaux", Paris 1888, of which a second edition (1897) and several translations appeared.

The synthesis of nicotine by Pictet (1895–1904) attracted universal attention, like that of tropine, completed by Willstatter a few years earlier. Up to that time, only a few quite simple alkaloids such as coniine, had been synthesized. From nicotine, Pictet passed on to the still more complex isoquinoline alkaloids, and his syntheses of laudanosine and of papaverine, both in 1909, are among his most notable achievements. About 1912, Pictet abandoned the study of the alkaloids; questioned many years later, he gave as the reason that he could not afford to let his students waste expensive material. He found a new field in the extraction of hydro-aromatic substances from coal by benzene, and was the first to study coal tar produced at low temperature in a vacuum. This led him to distil starch and cellulose under reduced pressure, when (in 1918) he obtained a large yield of lævoglucosan, $C_6H_{10}O_5$, an anhydride of glucose prepared previously in small quantity by Tanret from certain glucosides. Then, entering further into the field of carbohydrates, he synthesized maltose and lactose, and published in 1929 a synthesis of cane sugar. The latter work could not be confirmed by others and it would appear that, in his old age, Pictet was duped by his collaborator; some two years later he retired from his professorship.

Pictet was a corresponding member of the Paris Academy of Sciences, an honorary fellow of the Chemical Society of London, and an honorary member of the Dutch Chemical Society. Although until the foundation of the *Helvetica Chimica Acta*, his work was principally published in German, Pictet was more at home in France; he loved Paris, and was a connoisseur of French cookery. The writer well remembers Pictet's disdain when the latter asked a Dutch colleague for his impression of a famous restaurant, at which they had just lunched, and obtained the reply: "Mais c'était bien cher!"

G. B.

Mr. A. M. Sillar

ARTHUR MOLYNEUX SILLAR, one of the early pioneers of electric lighting, died on March 6 at the age of seventy-two years. He was educated at Shrewsbury, and from 1882 until 1886 he was engaged with the Jablochkoff Electric Light and Power Co. He was chief engineer to the Electrical Engineering Corporation until 1890, and in 1895 he with Mr. E. M. Lacey started practice as consulting engineers. His firm carried out the electrification of the Blackburn tramways in 1897, and in 1902 completed the Bournemouth tramways, this being the first example of a side rail slot system in Great Britain.

In conjunction with his partners, Sillar designed and inaugurated electric power systems for many local authorities and companies both in Great Britain and abroad. Amongst them were Belfast, Blackburn, Bournemouth, Colchester, Pekin, Salford, Swindon and Tientsin. He acted for many electric power companies and railways. He was also consulting engineer to the Post Office and to the London Chamber of Commerce. During the Great War, he was director of National Gauge Factories.

In 1922, Sillar was appointed chairman of the Association of Consulting Engineers, and took a leading part in the social functions of many engineering institutions. The long-established success of the Electrical Engineers' Annual Ball was mainly due to him and largely helped the Benevolent Fund of that Institution. He was well known and highly esteemed in engineering circles. He has left a son who is an engineer with the Calcutta Electric Supply Corporation.

WE regret to announce the following deaths:

Sir Henry Hadow, C.B.E., principal of Armstrong College, Newcastle-upon-Tyne in 1909–19, vice-chancellor of the University of Sheffield in 1919–30, on April 9, aged seventy-seven years.

Dr. William T. Hornaday, formerly director of the New York Zoological Park, known for his work in connexion with the protection of wild life, on March 6, aged eighty-two years.

Prof. Sydney Young, F.R.S., formerly professor of chemistry in Trinity College, Dublin, on April 8, aged seventy-nine years.

News and Views

World Congress of Faiths (Continuation Movement)

As a result of the first World Congress of Faiths held in London in July 1936 (see NATURE, 138, 1; 155) a Continuation Movement to promote further the objects of the Congress was inaugurated with the Maharaja Gaekwar of Baroda as international president and Sir Francis Younghusband as chairman. It is now announced that a week-end intensive Congress will be held at Oxford on July 23–27, when the subject for deliberation will be "The World's Need of Religion". Addresses for discussion will be delivered by members from the different religions, and devotional meetings will be led by representatives of the various faiths. A symposium on "Can Politics replace Religion?" will be conducted from three distinctive points of view, and at a public meeting to be held in the Oxford Town Hall on the evening of July 24 addresses will be given on the subject of "The World's Need of Religion". It may be recalled that the Congress was organized to promote a spirit of fellowship among mankind through religion, and "to awaken and develop a world loyalty, while allowing full play for the diversity of men, nations and faiths". It is, therefore, essentially a movement that is both international and inter-denominational in the broadest sense of the term.

AT the successful London meeting, a large number of distinguished and representative members of the great religious faiths of the world were present, and spoke in support of the objects of the Congress, more especially in so far as they were directed to the promotion of world peace through the co-operation of men of the spirit in all countries and of all faiths. Since, however, the spirit of fellowship, which it is believed by promoters of the Congress is latent in man, needs to be intensified if it is to work out its effect to the full, the Continuation Movement seeks support with that end in view. Particulars of the Oxford meeting, at which accommodation for members will be provided at Balliol and Somerville Colleges, forms of application for membership, etc., are to be obtained from the Secretary, World Congress of Faiths, B/M Congress, London, W.C.1.

Cultural Contrast and Government in India

THE debate in the House of Lords on April 8 on the situation in India arising out of the inauguration of the new constitution made apparent, in the gravity of the issues shown to be involved, the need for a common idiom as between races and creeds such as is sought by the World Congress of Faiths. The lucid and well-balanced statement by the Marquess of Zetland in particular brought into high relief the justice of the frequently repeated contention that, in the clash of culture contact, understanding grounded on a knowledge of local culture and history alone can alleviate and remove the inevitable misconceptions and friction, which arise in the fusion of mutually alien civilizations. In India, the freedom of democratic institutions, notwithstanding the misgivings expressed by those who claimed with reason an understanding of Eastern mentality, has been bestowed upon an oriental community, which has behind it a lengthy tradition, extending over centuries and even thousands of years, of submission to autocratic control. The resulting conflict, if the intransigence of the extremists of the Congress Party be ignored, is expressed on one side in Mr. Gandhi's explanation and amplification of the demand for the unqualified and unconstitutional abrogation of the powers of the Provincial Governors, and on the other in Lord Lothian's letter to *The Times* of April 6 and Lord Zetland's speech in the House of Lords. On one hand, the British Government and the British people are willing and anxious now that the die has been cast, to give every freedom to the peoples of India to win their way through responsible government to a position of independence within the Empire, yet they are at a loss before the naive simplicity of the over-subtle Eastern mind; on the other hand, Mr. Gandhi, who, whatever opinion may be held of his policy and political methods in the past, embodies, especially in the eyes of his co-religionists, all that is best and highest in Hindu culture, in common with others of his creed is unable to enter into an understanding of an honestly intentioned generosity which rests upon no legal bond as he understands it.

Hours of Employment of Young Persons

A SERIOUS gap in our social legislation is exposed by the report of the Committee on the Hours of Employment of Young Persons. Since the Factory and Workshop Act of 1901 and the Shops Act of 1934, limits have been set to the number of hours during which a young person may work, as well as to the amount of overtime and night work. A large class, estimated by the Committee at 125,000, still remains which is not covered by this legislation and is liable to be grossly overworked. This class consists mainly of van boys, hotel pages, messengers, cinema ushers, and the like. The chief objections to these forms of employment are that they are often spread out over long hours, that in busy periods there is no limit to the possible overtime that may be demanded and that often the jobs lead nowhere. That such a position should arise in so new an industry as the cinema industry indicates how sadly overdue is a real attempt to deal with recruitment on quantitative as well as qualitative lines, and the whole report strengthens the case for a scientific approach to the question of recruitment. The recommendations of the Committee include fixed hours, intervals for rest, weekly holidays, strictly limited overtime for young persons more than sixteen years of age and its prohibition for those less than sixteen, as well as prohibition of night work for a period of 11 hours, and it is considered essential that immediate steps be taken to give statutory protection to the unregulated young persons covered by the Report. It is recommended that the regulation of the hours of work of those employed in connexion with factories, docks and warehouses should be entrusted to the Factory Department of the Home Office and, for the remainder, to the local authorities responsible for administering the Shops Acts.

Traffic in Women and Children in the East

A CONFERENCE of Central Authorities in Eastern Countries on the Traffic in Women and Children in the East opened at Bandoeng, Java, on February 2, as the outcome of investigations in 1930–31 by the League of Nations' Commission of Enquiry into the Traffic in Women and Children in the East. This Commission established that the international traffic in Oriental women and girls in the Near, Middle and Far East is, in the aggregate, large. The bulk of this traffic is Asiatic women from one country to another, mainly in victims of Chinese race, Japanese, including Korean and Formosan, coming next in numerical importance, and other nationalities being very much less represented. Traffic in Occidental women to the East, with certain exceptions, chiefly in the Mediterranean Near East, has markedly decreased. The agenda of the Conference consisted of six points covering the chief suggestions of the report for closer collaboration between central and other authorities; and between authorities and voluntary organizations; the protection of migrants, especially minors, victims, or potential victims, of the traffic; the employment of women officials; the question of the continued existence of licensed or tolerated houses, which are the chief agents of internal and international traffic in the Indian and Pacific Oceans; and problems involved in the position of women of Russian origin in the Far East. Nine Governments, including the United Kingdom (Governments of the Straits Settlements, Federated Malay States and Hong Kong), China, France, India, Japan, the Netherlands, Portugal, Siam and the United States of America participated, as well as representatives of the International Criminal Police Commission.

Exhibition of Chemical Engineering

AN exhibition, Achema VIII, devoted to chemical technology, in which nearly three hundred firms have already arranged to take part, will be held in Frankfort-on-Main on July 2–11. Concurrent with the exhibition will be held the National Congress of German Chemists, the semi-centenary of the Verein Deutscher Chemiker, thereby providing the organizers of the exhibition with a unique opportunity of establishing the importance of the chemical engineer to the modern industrial community. The Hohenzollernplatz near to the University has been selected as the site of the exhibition, which will be housed in four separate buildings. In the first of these buildings, having a floor area of 125,000 square feet and subdivided into three sections, termed Halls I, II and II*a* in the official foreword, will be shown scientific apparatus including measuring, regulating and laboratory equipment, technical plant constructed from non-metallic materials, as well as machines for the manufacture, machining and shaping of synthetic materials. Two buildings, namely Hall III, having a floor area of 20,000 square feet, and Hall IV, with a floor area of 100,000 square feet, will be used to display technical equipment on a large scale such as machines and complete plants for the chemical and associated industries and similar exhibits. The last building is again subdivided into two parts, namely Hall III*a* with a floor area of 10,000 square feet which will be devoted to that part of the chemical industry engaged on the production of, and spinning of, artificial fibres, and Hall III*b* with a floor space of 5,000 square feet in which will be shown the publications of the various German scientific associations and societies. Arrangements have also been made for special meetings, conducted tours, showing of industrial films, excursions for visitors to the exhibition. Further information can be obtained about the meeting by application to the Deutsche Gesellschaft fur Chemisches Apparatewesen EV, Achema Bureau, Berlin W 35, Potsdamer Strasse 103*a*.

Broadcasting in 1936

A REVIEW of the activities of the British Broadcasting Corporation during 1936 is given in the tenth annual report of the Corporation, which has recently been issued as a white paper (Cmd. 5406. London: H.M. Stationery Office. 6*d*. net). The year 1936 was conspicuous in the first instance because three successive kings were involved in turn in certain of the broadcast programmes. The report contains details of the outstanding items in a wide variety of programmes broadcast throughout the year, during which the home transmitters were in operation for 71,123 hours, of which the proportion of breakdown periods was 0·031 per cent. The corresponding aggregate time for the Empire transmitters was 16,577 hours, an increase of more than forty per cent on the figure for 1935. Apart from the maintenance of the stations and plant required for these services, the activities of the B.B.C. on the engineering side included the putting into service of the high-power transmitter at Lisnagarvey in Northern Ireland, the completion of a similar transmitter at Burghead in the north of Scotland and the construction of a medium power transmitter at Beaumaris in Anglesey, which has been put into service in the current year. Good progress has also been made with large-scale extensions to the Empire Station at Daventry. These include the commencement of a third transmitter of considerably higher power than those now in operation; together with the erection of additional masts for an improved aerial system, which is the outcome of experiments carried out at the Empire Station since it was first put into service in 1932.

Mention must also be made of the considerable experimental and engineering work involved in the equipment of the London Television Station at Alexandra Palace towards the end of the year under review. The report concludes with a summary of the financial position of the Corporation as at December 31, 1936.

The Need for Motor-car Inspection

REVISED regulations for the construction and use of motor vehicles in Great Britain have just been issued by the Ministry of Transport. They provide, among other matters, for the testing of brakes, steering gear, etc., of a vehicle on the road. In about a dozen of the States forming the U.S.A., it is compulsory for motorists to have their cars inspected to see that they comply with safety regulations. According to a recent note issued by Science Service, of Washington, D.C., it is an even chance whether the motorist will find that his car falls below the requirements for safety on the road or not. The most common fault is bad brakes, but it is not unusual to find that lights are out of focus and wheels out of alignment. In some cases, the owner finds that it would cost him more than his car is worth to make the repairs and so it is relegated to the scrap heap, an action which may possibly have saved the lives of other people as well as his own. Last year in Pennsylvania alone, nearly 15,000 of the vehicles were found to be decrepit, and quietly passed out of circulation. Whenever inspection laws are passed in a State, it has been noticed that there is a great decrease in the number of 'collegiate' models which run on the roads on four wheels with no brakes. It is impossible to say what percentage of highway accidents can be attributed to mechanical defects of the cars, as after a wreck there is little left to test. It is reasonable to conclude that when about half the cars in a State have faulty brakes, they are to blame for some of the tragedies which occur. Because cars are fitted with good tyres and good brakes initially, we are apt to forget that the average car on the road is nearly five years old and is generally slightly shaky. Railway trains and air liners, operated by experts, have to pass a rigid inspection to see whether they are safe. Motor-car drivers are usually amateur mechanics; it is rash to assume that their equipment is safe.

Education in Canada

CANADIAN education, as seen in the course of a four-months winter visit, was the theme of a paper read by Dr. F. H. Spencer, late chief inspector, Education Department, London County Council, before the Royal Society of Arts on November 11 last, and recently made available in print. Although the purpose of the visit was to lecture on English, not to investigate Canadian education, and Dr. Spencer disclaims any title to be listened to as an authority on this subject, his comparisons of school buildings, organization, teacher-training and university extension work in Canada and in England are enlightening, even though admittedly superficial. The most satisfactory of his impressions was of the prevalent enthusiasm for popular education, and the most unsatisfactory was of excessive regimentation alike in the primary and in the secondary schools. He was struck by the importance of the service rendered by the universities through their extension departments, and especially their correspondence courses, to remote but interested and ambitious students in the backwoods. The travels of the university extension tutors in the winter into such remote regions provide them with a stimulating adventure—an experience to which a counterpart has sometimes been found in Great Britain, for remoteness is not always to be measured in miles. In the course of the discussion following the reading of the paper, Prof. Krug of Mt. Allison, New Brunswick, observed that there have been few more worthy contributions to Canadian education and to Empire unity than the visit paid to Canada last year by a group of British school administrators and inspectors; a visit which made, he said, a really deep impression.

Physiology and Hygiene in Education

THE place of physiology and hygiene in general education has yet to be effectively established. Intellectual assent has been generally accorded to Herbert Spencer's dictum—that such a course of physiology as is needful for the comprehension of its general truths, and their bearings on daily conduct, is an all-essential part of a rational education—but those responsible for curricula have not so generally given practical effect to such assent. The subject has lately been investigated by Dr. J. P. Rogers for the United States Office of Education. In his report on "Instruction in Hygiene in Institutions of Higher Education" (Washington, D.C.: Government Printing Office. 10 cents), he observes that only a third of the colleges and universities require attendance at a course in hygiene by their students, and it is rare that any instruction concerning the human body is furnished in the last three years of secondary school work. He quotes some interesting criticisms by university authorities of the methods of instruction in use: one president remarks "my observation has been that this course has been too technical and not sufficiently practical. *I have yet to find an instructor who can put the information in a practical way*". It takes an artist, says Dr. Rogers, to fill such a requirement, and the best teacher of hygiene is the master and not the servant of that body of tradition which passes for 'science' in his day.

Extension of Scientific Buildings in Oxford

A FORECAST of extensions of scientific departments in Oxford is contributed by Dr. A. S. Russell, of Christ Church, to the spring number of *Oxford*, the journal of the Oxford Society. Within three or four years, a new physics laboratory for Prof. F. A. Lindemann will, it is hoped, be put up in the Parks, when the Clarendon Laboratory, now occupied by him, could be adapted to the uses of the Department of Geology now inadequately housed in the Museum. These improvements are expected to be closely followed by the erection of a great new physical chemistry institute. "The Oxford school of chemistry will then be without doubt the finest in the Empire". The article ends with a plea for the award of college fellowships to more of the best of the young men holding University posts in science, especially in the less popular sciences—engineering, zoology, botany, geology. The same number of *Oxford* has noteworthy articles on "Politics or Poetry ?", on university camps for the unemployed (which have amply justified the money and effort expended on them), and on women as housing estate managers on the Octavia Hill system.

Medical Research in South Africa

MUCH important research work is summarized in the annual report of the South African Institute for Medical Research for 1935. The use of a 'mixed vaccine' for the prevention of pneumonia among the Rand native miners has been continued with encouraging results. In the Biochemical Department, a strange finding was that the leaf of a plant belonging to the yam family contained forty times as much iron as spinach. Lucerne has been found to be suitable for human consumption as an anti-scorbutic, and several mines are now including this plant as part of their vegetable ration. The influence of South African snake venoms, previously tested on animal tumours, has now been tried on human cancers. Cobra venom often produced a relief of pain in cases of cancer, but not always ; and no permanent beneficial effect resulted. There was no evidence that African snake venoms had any action on the majority of malignant tumours in man. Rodents to the number of 2,026 were examined for presence of plague infection, of which 51 were found to be infected with *B. pestis*.

Standardization of Microscope Fittings

IN order that the microscope objectives of different makers might be interchangeable for use with the microscope stands of other makers, the Royal Microscopical Society of London drew up in 1858 a specification for the screw thread of objective and of nosepiece. This specification was revised in 1896, 1915 and 1924, and in its final form has been generally adopted by microscope makers at home and abroad. In view of the increasing use of apparatus above the eyepiece, a committee of the Society has now drafted specifications of standard sizes for the external diameter of the eyepiece end of the draw-tube and limits for the outside diameter of the eyepiece shoulder ; these have been adopted by the Council of the Society and are detailed in the December issue of its journal (*J. Roy. Micro. Soc.*, 56, 377–380 ; 1936).

The Smithsonian Institution

THE report of the secretary of the Smithsonian Institution for the year ended June 30, 1936, refers to the continuation of the study of the relation of weather to changes in the sun's radiation. Two papers by Dr. C. G. Abbot appear to prove that the short interval changes of solar radiation are of major influence on the weather for at least the following two weeks. To test this promising method of weather forecasting, seven additional observing stations are required, but a bill to provide funds for this purpose passed by the Senate was rejected later. The Division of Radiation and Organisms has continued its work on the dependence of carbon dioxide assimilation in wheat upon the wave-length of radiation as well as its experiments on the effect of ultra-violet rays on algæ and of light of different wave-lengths on the growth of tomatoes. An extremely sensitive and quick-acting spectroscopic method has been developed for measuring the concentration of carbon dioxide, as well as a highly sensitive robust thermocouple. The Institution has also published the latest results of the high-altitude rocket experiments of Dr. R. H. Goddard, whose earlier work it supported for twelve years. In the most recent trial flights, the liquid-propelled rocket attained a height of 7,500 ft., its automatic stabilizer keeping the flight vertical. Sales of the Smithsonian Scientific Series continue to increase, and in addition to a summary of the work of the Institution and the financial report, the present report of the secretary includes appendixes giving more detailed accounts of the work of the National Museum, the Bureau of American Ethnology, the International Exchanges, the National Zoological Park, the Astrophysical Observatory, the Division of Radiation and Organisms, the Smithsonian Library, the National Gallery of Art and the Freer Gallery of Art.

National Museum of Wales

THE twenty-ninth annual report, for the year ending September 30, 1936, of the National Museum of Wales, gives evidence of steady progress. By an increase of £500, the Treasury annual grant for the year was raised to £17,375, and a detailed report, furnished to H.M. Treasury by the Council, and pointing to the increased expenditure necessitated by the opening of the east wing, had the effect of inducing an allocation of £18,500 for the current year and a promise of £20,000 per annum as from April 1, 1938. The increased grant has enabled the Council to found a Specimens Purchase Fund, to be applied to the purchase of collections or specimens of outstanding importance as the need arises, and to create a Department of Folk Culture and Industries, which was responsible for a special temporary exhibition of Welsh furniture. At that exhibition nearly a hundred examples of furniture, made or used in Wales, and ranging from Tudor to Georgian times, were gathered together. The list of free public lectures displays refreshing variety, and the installation of a 16 mm. sound film apparatus should add to the popularity of the Reardon Smith Lecture Theatre.

Dairy Research in Scotland

THE seventh annual report of the Hannah Dairy Research Institute, Kirkhill, Ayr, contains an account of the developments, finance, and research work of the Institute during the year ending March 31, 1935. An important development has been a study of practical problems connected with grass conservation, made possible by a commercial grass-drying plant placed at the disposal of the Institute by the Agricultural Research Council. The condensing and drying of milk and the manufacture of canned milk products have also been investigated. Research work includes experiments on the nutritive value of milk for calves, the biochemistry of milk secretion, and studies on bovine tuberculosis, contagious bovine abortion and bovine mastitis. The pasteurization of milk and the bacteriological grading of milk have also been investigated. An inquiry into the consumption of milk by children of school age is in progress. As regards finance, State contributions and grants provide £8,000 a year, but an additional £2,000 per annum is required if the Institute is to carry through its full programme of work.

Social Services in the Soviet Plan for 1937

According to the Soviet Union Year Book Press Service, the provisions of the 1937 Plan for the national economy of the U.S.S.R. in regard to the cultural and social services include the following: *Science.* 924·2 million roubles (about £93 million) for the maintenance of scientific institutions in 1937, as against 797·5 million roubles (£80 million) in 1936. Out of this sum, 245 million roubles (about £25 million) will be expended on general capital construction for the needs of science, to include an expenditure of 40 million roubles (£4 million) on putting up new buildings to house the institutions of the All-Union Academy of Sciences, and 25 million roubles (about £3 million) for the building of the All-Union Institute of Experimental Medicine. *Health Protection.* A sum of 7,528·1 million roubles (£753 million) for health protection in 1937, as against 5,803·5 million roubles in 1936. This sum includes an expenditure of 1,000 million roubles on buildings. The number of hospital beds in 1937 will be increased to 619,800, as against 564,000 in 1936; maternity beds to 11,078, as against 6,000 in 1936.

Truth and Propaganda

An article by Prof. M. Polanyi in *The Manchester School*, 7, No. 2, entitled "The Struggle between Truth and Propaganda", although a somewhat polemic criticism of S. and B. Webb's "Soviet Communism: a New Civilization", is of wider interest through its plea for a more determined stand by scientific workers and other intellectual workers for free and impartial criticism against propaganda. Unless thinkers make a fresh stand everywhere, regardless of political consequences, for the criticism which is freely admitted in a democracy, truth will remain powerless against propaganda, the power of which has been immensely enhanced by new means which scientific discoveries and their application have put in its hands. The reconciliation of rival social doctrines, which alone can save Europe from destruction, cannot be attained except through tolerance and the acceptance of truth and facts, no matter how unpalatable or disconcerting to particular theories.

Germany and Science: Yesterday and To-day

A correspondent has pointed out that the speech at the Heidelberg jubilee by Reichsminister Rust, which was referred to in Nature of January 16, p. 98, stands in poor contrast to an equally proud speech of Helmholtz delivered in 1869 (*Les Mondes*, 21, 552). Speaking at Innsbruck at a gathering of German scientific workers and medical men, he claimed that Germany held the first place in the development of natural sciences because the German *savants*, unlike their French and English colleagues, could proclaim truth as they found it, without regard to the opinion of the world, to social and religious prejudices. Our correspondent remarks that there was more of Athens than of Sparta in such men.

Prof. H. E. Armstrong

The familiar and welcome figure of Prof. H. E. Armstrong has been missed in scientific circles for several months; and his caustic comments upon contemporary views and events—both scientific and unscientific—have similarly been absent from the pages of Nature and of other periodicals. Though, however, general physical weakness prevents Prof. Armstrong from moving about and attending meetings in the way he has done all his life, yet he still takes active interest in progressive work of every kind and asks his friends not to hesitate to communicate with him. He enters his ninetieth year on May 6, and maintains the indomitable and fearless spirit which has always characterized him. "I should like", he wrote a short time ago to an old friend, "to start over again in the hope that knowledge may be so made use of that some measure of tolerance and common sense will be infused into the nations."

Seventh International Congress of Genetics

The following communication has been received from Prof. Otto L. Mohr, of the Anatomical Institute, University, Oslo, chairman of the International Committee for Genetics Congresses: "The VIIth International Genetics Congress which was going to be held at Moscow, U.S.S.R. this summer has been postponed. According to the information received from the Organization Committee, a number of scientists and institutes have requested this as they wished to be better prepared for the congress. The Academy of Sciences and the Organization Committee have now extended an invitation to hold the congress in Moscow in August, 1938. Conforming with the mandate given to the Permanent International Committee for Genetics Congresses, the entire matter will be put before this committee for decision. At present it is certain that no International Genetics Congress will be held in 1937."

British Empire Cancer Campaign

At the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on April 12, the following grants, totalling £2,900, were made, in addition to the bulk grants of last November and January: £1,000 to be placed at the disposal of

Dr. F. Dickens, director of research of the North of England Branch of the Campaign, at Newcastle, for the continuation of the special short-wave investigations being carried out under his direction on behalf of the Scientific Advisory Committee at headquarters; £1,200 for the purchase of a plaque of radium in use by Dr. F. G. Spear at the Strangeways Research Laboratory, Cambridge; an additional grant of £300 for the calendar year 1937 to the Westminster Hospital; an additional sum of £300 to Mr. F. C. Pybus for the salaries of his assistants and expenses during the second half of 1937 and a grant of £100 to Dr. L. H. Gray, at Mount Vernon Hospital, in connexion with the neutron investigations.

Rockefeller Travelling Medical Fellowships

THE Medical Research Council has been entrusted by the Rockefeller Foundation of New York with £3,000 annually, for three years in the first instance, for the award of travelling fellowships in medicine to candidates in the United Kingdom. This benefaction renews an arrangement which had been successful during an earlier period, but which had latterly been interrupted during a revision of the Foundation's general policy. These Rockefeller fellowships are intended for graduates who have had some training in research work in clinical medicine or surgery or in some other branch of medical science, and are likely to profit by a period of work at a chosen centre in the United States or elsewhere abroad before taking up positions for higher teaching or research in Great Britain. Five or six fellowships will be available annually, and applications for the academic year 1937–38 will be invited in May. It is of interest to recall an analysis which was made, at the end of the previous ten-year period, of the positions occupied by the seventy men and women who had completed their tenure of Rockefeller Fellowships awarded by the Council. This showed that twelve were professors in universities, that thirty-six others occupied whole-time positions for teaching and research, and that a further sixteen held part-time appointments of the same kind.

Announcements

SIR WILLIAM BRAGG will deliver the forty-third James Forrest Lecture before the Institution of Civil Engineers on April 27, at 6 p.m. The title of Sir William's lecture will be "The Crystal and the Engineer".

PROF. J. CHADWICK will deliver the twenty-eighth Kelvin Lecture before the Institution of Electrical Engineers on April 22 at 6 p.m. The subject of the lecture will be "The Elementary Particles of Matter".

THE triennial Burton Memorial Medal of the Royal Asiatic Society has been awarded to Sir Arnold T. Wilson. The Burton Memorial Lecture will be given by him at the Society's rooms on May 27, when the Medal will be presented by Dr. Bertram S. Thomas.

THE following appointments in the Colonial Service have recently been made: A. W. Hart, veterinary officer, Nigeria; S. H. Shaw, geologist, Palestine; I. E. James (agricultural officer), senior agricultural officer, Nigeria; A. S. Richardson (senior agricultural officer, Tanganyika), deputy director of agriculture, Uganda; R. S. Pelly (assistant conservator of forests, British Honduras), assistant conservator of forests, Sierra Leone; F. G. Taylor (telegraph engineer, Railway Department), wireless engineer and broadcast officer, Sierra Leone.

PROF. A. BESSEMANS, pro-rector of the University of Ghent, has been elected member of the German Academy of Natural Sciences at Halle.

DR. WALTHER HORN, director of the German Entomological Institute, has been nominated corresponding member of the Finnish Entomological Society and honorary academician of the Museum of La Plata.

THE Corbalan Melgarejo prize founded in Chile to honour the memory of Dr. Ramon Corbalan Melgarejo, author of the Sanitary Codex of Chile and first director-general of the Health Service of the Republic, has been awarded by the Medical Society of Chile to Joaquin Luco Valenzuela.

THE French Association for Researches on Hearing and Deafness has recently elected M. Auguste Lumière as president. The Association consists of medical practitioners, acoustic technicians, hygienists and all interested in the campaign against deafness. The life subscription is 500 francs and the annual subscription 50 francs. Further information can be obtained from the general secretary, 143 bis Promenade des Anglais, Nice.

A MUSEUM has recently been founded at Lennep in Rhenish Prussia, the birthplace of Wilhelm Conrad Röntgen, illustrating the significance of X-rays and the development of Röntgen technique.

THE fifth International Hospital Congress, in which more than fifty countries will take part, will be held in Paris on July 6–11. Further information can be obtained from the Secretariat, Administration de l'Assistance Publique, 3 Avenue Victoria, Paris IV^e.

THE seventeenth Congress of Anthropology and Prehistoric Archæology will be held at Bucharest on September 1–8 in the Palace of the Faculty of Law. Further information can be obtained from the general secretary, Prof. Nicolas Minovici, Institut Medico-légal, Bucharest, or from the Secretariat, Institut international d'anthropologie, 15 rue de l'Ecole de médecine, Paris.

ANOTHER volume of "Researches published from the Wards and Laboratories of the London Hospital" for the year 1936, has been issued by the Publications Committee (London: H. K. Lewis and Co., Ltd. 7*s*. 6*d*. net). The papers selected cover a wide field, and are valuable contributions to medical science.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 677.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Effects of Traffic Disturbance and Night Illumination on London Starlings

THAT the breeding period of birds with a relatively brief annual reproductive season could be shifted to any time of the year by manipulating lighting conditions, regardless of temperatures, was first shown in 1924[1]. The subject has since been investigated by numerous other workers, but a specific answer as to how the light induces the effects that can be so readily demonstrated has not yet been found. While it has been shown that the principle applies widely to birds, some forty species of which have now been examined by various investigators, it has also been shown to be effective in certain mammals, reptiles, amphibians and fish. Evidence that light falling on the eye, or other receptor, stimulates the pituitary, which in turn activates the gonads, is gathering weight, but is not yet wholly convincing.

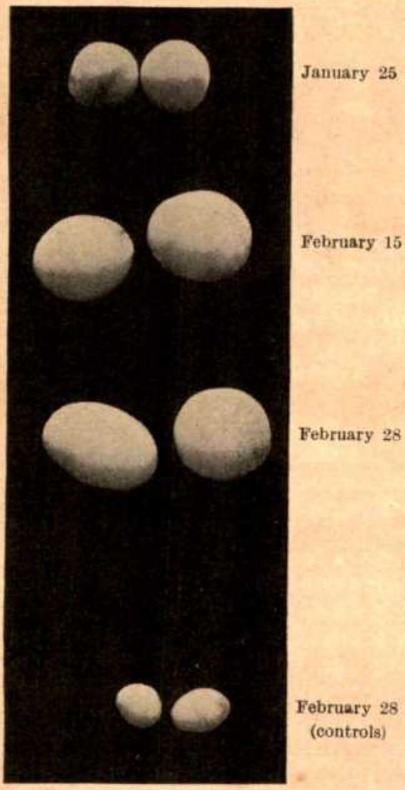

Fig. 1.

TESTES OF JUNCOS. × APPROX. 15.

Nine years ago, an attempt was made to induce winter development of the gonads in the migratory finch, *Junco hyemalis*, by substituting periods of activity without light for periods of artificial illumination. The apparatus and results were fully described in these columns[2]. On account of the lateness of the season (March 17–April 28) it seems possible that the striking results obtained could have been due in part to the fact that recrudescence of the organs, having already begun under the influence of lengthening days, proceeded under the stimulus of forced exercise, and that the results might have been different if undertaken earlier in the winter.

The experiment has now been repeated with the same apparatus and the original species, the Canadian junco (males only), but commencing on January 4, 1937. The only window of the room used was shuttered nightly from 5 p.m. until 9 a.m. A small electric bulb at the level of the ceiling was the sole source of illumination, and its rays could not fall directly either on to the control or experimental birds, their cages standing on the floor under opaque shades. The bulb burned for longer periods nightly, commencing always at 5 (except for the first week when the room was shuttered at 4) and continued the first day for 7½ minutes, 15 the second, 22½ the third, 30 the fourth, and so on until 11 p.m. had been reached on February 28, when the last birds were killed for examination. Synchronously with the burning of the light, a mechanical device gently disturbed the experimentals and prevented them from falling asleep for an additional 7½ minutes daily. The controls slept without interruption from 5 o'clock onwards.

The outcome is illustrated in Fig. 1. The result is not as striking as on the previous occasion even though the total time involved was longer (eight weeks as against six), but recrudescence of the testes was nevertheless induced among the experimentals. Those of the control have remained at the winter minimum and show not the slightest effect of the artificial illumination to which the bird was exposed for two months.

Bissonnette[3] repeated this undertaking on starlings, but found that he could not induce development of the gonads by compulsory exercise in dim light. He did, however, get two specific results. One was excess of the pigmentation that is so characteristic of starlings' testes in the early stage of development: the other was a speeding up of the rate of recrudescence when his birds, after periods of compulsory exercise, were thereafter exposed to increased periods of light of much greater intensity.

It occurred to me during the present winter, on reaching London and noting hundreds of starlings roosting on various public buildings in the West End, that the feeble light falling on them at most of their roosts must be far below the intensity shown by various investigators to be effective in inducing development of the gonads in birds. Practically all of them, however, were roosting over main traffic routes and were being sufficiently disturbed by the din and tumult below them to stay awake intermittently until the small hours of the morning. It was decided to collect samples for examination early in January, but when the time came, difficulties inherent in the general situation came with it. Collecting birds at night in the centre of London was more easily said than done, and it was finally February 10 before a dozen birds from a West End roost had been procured for examination. Some forty country birds have also been obtained for comparison. The results are illustrated in Figs. 2 and 3.

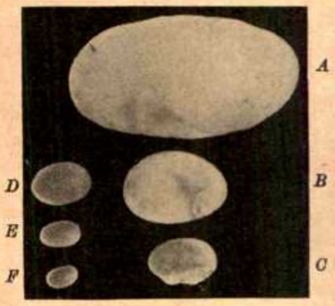

Fig. 2.
TESTES OF STARLINGS. *A*, *B*, *C*: LONDON BIRDS (FEB. 10). *D*, *E*, *F*: COUNTRY BIRDS (FEB. 17–26). × APPROX. 2.

We have since determined that at the spot from which the London birds were obtained, the needle of a Weston lightometer (registering foot candles) fails to record even a vestige of a flicker. I am informed by the makers of the light involved that it is a 1,500-watt tungsten filament lamp and that the red values, considered by Bissonnette as of particular potency in their effect on gonad stimulation, are probably 10 per cent *below* those of a smaller and less-efficient bulb of the same nature. Such bulbs were used in my original experiments and have been adopted by most other investigators.

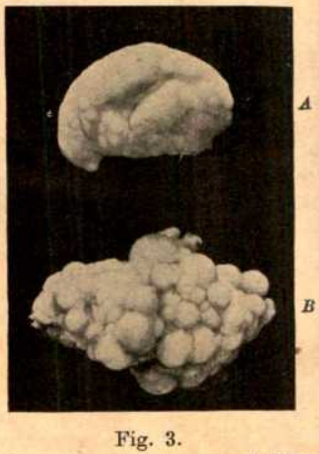

Fig. 3.
OVARIES OF STARLINGS. *A*, BEDFORDSHIRE BIRD (FEB. 17); *B*, LONDON BIRD (FEB. 10). × APPROX. 5.

A review of this topic in its entirety is in preparation. Space required for an adequate discussion precludes the possibility of doing so here, but it seems worth while to put the facts on record for the consideration of others.

Equilibrium and Kinetics in the Gaseous State and in Solution

Diene syntheses are reversible associations of the type $a + b \underset{kd}{\overset{kf}{\rightleftarrows}} c$. The equilibrium constant $K = \frac{k_f}{k_d} = B \exp HR/T$ has been measured for four of these reactions.

(1) *cyclo*pentadiene + α-naphthoquinone ⇄ *cyclo*pentadiene-α-naphthoquinone.

(2) *cyclo*pentadiene + benzoquinone ⇄ *cyclo*pentadiene-benzoquinone.

(3) *cyclo*pentadiene + *cyclo*pentadiene ⇄ di*cyclo*pentadiene.

(4) *cyclo*pentadiene + acrolein ⇄ endomethylenetetrahydrobenzaldehyde.

The results of the measurements are in Table 1.

TABLE 1.

Reaction No.	Measurements in	$B \times 10^7$ l./gm.-mol.	H kgm.-cal.	Temp. range
1	Benzene	1·8	16·9	8–79°
2	Benzene	8·3	17·7	8–79°
3	Paraffin	13	16·8	0–175°
	Gas	1	17·9	25–100°
4	Gas	6·8	18·4	108–242°

Values of B between 10^{-6} and 10^{-7} l./gm. mol. are observed in both states and hence the statistical probability of the formation of c from a and b, whether in the gas phase or in solution, is of the same order of magnitude for all the reactions. Also H, the heat of reaction, is nearly the same for all four diene syntheses, a value of about 17 kgm.-cal. being observed in both states.

The B and H values for Nos. 1[1], 2[1] and 4[2], and for No. 3 in paraffin solution[1] were obtained by determining the temperature dependence of k_f and k_d. In order to obtain B and H for No. 3 in the gas phase the solubilities, L, of gaseous *cyclo*pentadiene and di*cyclo*pentadiene in paraffin were determined over a range of temperatures. L = concentration solution/concentration gas $= C \exp \lambda/RT$ where the non-exponential term C is a measure of the statistical probability of dissolution, and λ is the heat of solution. Van't Hoff's equation connecting the equilibrium constant in two states with solubilities was used in the form $B_g \exp H_g/RT = B_s \frac{(C_a^2)}{(C_c)} \exp (H_s+2\lambda_a-\lambda_c)/RT$ where the subscripts g and s refer to gas and solution and a and c refer to *cyclo*pentadiene and di*cyclo*pentadiene respectively. The following values were obtained: $C_a = 1 \times 10^{-3}$, $\lambda_a = 7{\cdot}13$ kgm. cal., $C_c = 2 \times 10^{-5}$, $\lambda_c = 13{\cdot}1$ kgm.cal. The non-exponential term of the solubility is larger for *cyclo*pentadiene than for di*cyclo*pentadiene, and the heat of solution of *cyclo*pentadiene approximately equals half the heat of solution of di*cyclo*pentadiene.

TABLE 2.

Measurements in	A(l./gm. mol.-sec.)	Activation energy E (kgm.-cal.)	Temp. range
Gas[3]	$1{\cdot}3 \times 10^6$	$16{\cdot}7 \pm 0{\cdot}8$	80–150° C.
Paraffin	$13{\cdot}0 \times 10^6$	$17{\cdot}4 \pm 0{\cdot}5$	0–172° C.

It was found that the reaction, 2 *cyclo*pentadienes → di*cyclo*pentadiene is homogeneous and bimolecular both in the gaseous state and in paraffin solution, and that the Arrhenius equation $k_f = A \exp - E/RT$ is obeyed. The 'constants' of the equation are given in Table 2.

The solubility of the gaseous *cyclo*pentadiene-*cyclo*pentadiene transition state in paraffin is defined by the ratio concentration solution / concentration gas = $C_t \exp \lambda_t/RT$ and can be estimated, using the following relationships which were deduced by Evans and Polanyi[4] and Wynne-Jones and Eyring[5].

$$C_t \sim \frac{A_s}{A_g}(C_a)^2 \text{ and } \lambda_t \sim E_g - E_s + 2\lambda_a.$$

Here C_t is a measure of the statistical probability of dissolution of the transition state, λ_t is the heat of solution, and the subscripts g and s refer, as above, to gas and paraffin solution.

As the solubility of *cyclo*pentadiene, the kinetic A values and the activation energies are known, it follows that

$$C_t \sim 1 \times 10^{-5} \text{ and } \lambda_t \sim 14 \text{ kgm.-cal.}$$

If these values are compared with the non-exponential solubility term and with the heat of solution of di*cyclo*pentadiene, it can be seen that the solubilities of the transition state and of the product are similar.

We are greatly indebted to Prof. C. K. Ingold for his continued interest in this work.

Origin of the Cochlear Effect

IN 1934 Hallpike and Rawdon-Smith advanced a tentative theory to account for the production of synchronous potential waves within the mammalian cochlea, in response to auditory stimuli[1]. According to this, the potential waves were held to be set up by movements of a membrane, thought to be polarized, and bounded on either side by the cochlear fluids. It has now proved possible to show that a membrane, polarized in such a fashion, will in fact yield potential waves of the required type.

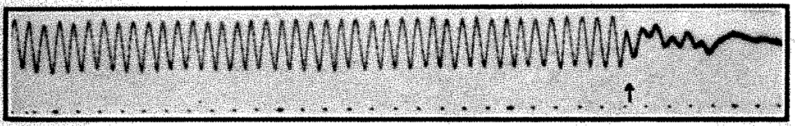

Fig. 1.

CATHODE RAY OSCILLOGRAM SHOWING RESPONSE FROM FROG'S SKIN TO PURE TONE STIMULUS OF FREQUENCY 140 ~ PER SEC. SOUND SWITCHED OFF AT ARROW. TIME MARKER: SMALL DOTS = 0·01 SEC.

The apparatus employed was arranged in the following manner. A piece of the skin of the common frog was stretched over the mouth of a glass tube approximately 1 cm. in diameter. The mouth of a second tube was caused to press lightly over this, in such a way that a fluid-tight seal was produced. The two tubes were then filled with frog's Ringer solution at pH 8. Into each tube a small platinum electrode was sealed so as to dip into the solution. It was then found that a steady potential of some 35 millivolts existed across the electrodes, and therefore across the skin, in the manner first demonstrated by du Bois Reymond[2].

Sounds generated by a heterodyne oscillator and loudspeaker were led by means of pressure tubing to a rubber membrane sealing off the opposite end of one of the glass tubes. The opposite end of the second tube was left open. On attaching the platinum electrodes to the input of a high-gain amplifier, the output of which was connected to a cathode ray oscillograph tube, it was found that potential waves of considerable magnitude (up to 0·5 millivolt) were produced by a stimulus of low frequency. As the stimulus frequency was increased, the efficiency of the mechanism fell off, as would be expected from a consideration of the inertia of the fluid system employed, many times greater than that of the mammalian ear.

The record shown in Fig. 1 was obtained using a stimulating frequency of approximately 140 ~ per sec. Its close resemblance to oscillograms produced in a similar fashion by the mammalian ear may be noted. A further point of similarity is provided by the fact that the application of ether to the skin abolished this effect; abolition of the steady potential previously referred to also ensued.

It is felt that this demonstration that a polarized membrane will yield such an effect lends indirect support to Hallpike and Rawdon-Smith's original theory.

Changes in frog skin potential were first observed by Motokawa[3] to arise from variations in the pressure head across the skin; a similar variation was observed for alteration of tension in the skin. Motokawa's results, and further data obtained here, indicate that such changes in potential are primarily due to changes in the values of the internal 'short-circuiting' (or local action) currents. These changes in turn result from changes in the local, and therefore also in the total, skin resistance. Support is lent to this contention by the fact that the required changes in total resistance can, in fact, be readily demonstrated.

From this evidence it appears that the potential waves recorded in response to acoustic stimuli may perhaps be ascribed primarily to such variations in local resistance, these in turn resulting from variations in pressure head and/or in tension set up by the vibrations communicated to the skin by the fluid with which it is surrounded. It is not impossible therefore that the cochlear effect may also be ascribed to some such mechanism.

Phase-Velocity of Electro-Magnetic Waves along the Ground

IN a recent publication, Colwell and his co-workers have recorded the results of experiments to determine the group velocity of electro-magnetic waves along the ground[1]. These experiments indicated that the speed with which a short pulse of radiation passed along the ground between two points situated some kilometres apart was considerably less than the velocity of light in free space. Their measurements were made on frequencies in the neighbourhood of 2,000 kilocycles per second.

In view of these results, it appeared to us that it would be of considerable interest to measure the phase-velocity of waves travelling along the ground. Apparatus was available at the Radio Research Station, Slough, with which such measurements could be made on a certain band of frequencies.

The apparatus consists essentially of a pair of similar aerials placed a known distance apart in the path of the wave and some means of comparing the phases of the signals induced in the two aerials. In the apparatus used, the output from each aerial was applied, after suitable amplification, to a pair of deflecting plates on a cathode ray tube. The fluorescent spot is thus subject to two deflections at right angles, these deflections being proportional to the signals in the two aerials respectively. The amplifiers and aerial circuits are first adjusted so that when equal and cophasal fields exist at the two aerials, the figure traced out on the oscillograph is a line at 45° to the axes of deflection of the spot. This preliminary adjustment is carried out by radiating a signal on the frequency to be used in the measurements, from an oscillator located midway between the aerials, it being assumed that in these circumstances equal and cophasal fields exist at the aerials. When a c.w. signal is received from a distant point on the line joining the aerials the figure traced out on the oscillograph tube is in general an ellipse, from which it is possible to determine the phase difference between the fields at the two aerials, and hence deduce the phase velocity of the wave passing between the two aerials.

If d = distance between aerials (cm.); f = frequency of wave (cycles per sec.); ψ = phase difference between signals in the two aerials (degrees); c = phase velocity of wave (cm. per sec.), it is easily seen that

$$\psi = \frac{360\,d}{c/f} \text{ or } c = \frac{360\,df}{\psi} \text{ cm. per sec.}$$

The aerial system used consisted of a pair of vertical aerials spaced 34·9 metres apart. Measurements were made on signals from a portable transmitter located about a mile from the receiving system, on the line of the aerials. The results are given in Table 1.

TABLE 1.

Frequency	Phase-Velocity
2·50 Mc./sec.	$3\cdot05 \times 10^{10}$ cm./sec.
2·90 ,,	$3\cdot10 \times 10^{10}$,,
3·29 ,,	$3\cdot00 \times 10^{10}$,,
5·95 ,,	$3\cdot00 \times 10^{10}$,,
7·60 ,,	$3\cdot10 \times 10^{10}$,,
10·92 ,,	$2\cdot75 \times 10^{10}$,,
11·70 ,,	$2\cdot80 \times 10^{10}$,,
11·70 ,,	$2\cdot85 \times 10^{10}$,,
15·05 ,,	$2\cdot90 \times 10^{10}$,,
Average	$2\cdot95 \times 10^{10}$,,

Over the range of frequency between 2·5 Mc. per sec. and 15 Mc. per sec. the measured velocity is seen to lie very close to the value $3\cdot0 \times 10^{10}$ cm. per sec. There is no indication of a marked change in velocity with frequency, from which we may deduce that the group velocity of waves along the ground is also within a few per cent of $3\cdot00 \times 10^{10}$ cm. per sec., that is, the velocity of light.

The accuracy of these results depends on the accuracy with which the distance between the aerials and the frequency can be measured and on the accuracy of the process of 'lining-up' the aerials. The measurement of distance was made to an accuracy better than 0·5 per cent and the measurement of frequency was made with a sub-standard wave-meter to an accuracy better than 1 per cent. It is considered that the accuracy with which the 'lining-up' process could be carried out and the accuracy of the measurements made on the ellipse are such that the overall accuracy is about 5 per cent or slightly better.

It remains to note that the observed values show discrepancies from the value $3\cdot00 \times 10^{10}$ cm. per sec. of more than the estimated experimental accuracy. These cannot be due to the effect of waves reflected from the ionosphere since at these ranges such waves would be incident vertically and would not affect the aerial system. The possibility of direct pick-up on the transmission lines coupling the aerials to receiver or on the receiver is ruled out by the negative results of direct experiments to test this. The possibility still remains of re-radiation from disturbing bodies near the receiving aerials.

It should be observed that, while these results are not in agreement with those of Colwell, Hall and Hill, the measurements made by them refer to a pulse which has travelled some kilometres, and which may not have remained quite close to the ground all the way, while our measurements refer to the velocity of the wave actually as it passed between two aerials on the ground.

These experiments were carried out as part of the programme of the Radio Research Board, and this note is published by permission of the Department of Scientific and Industrial Research.

Cosmic Ray Showers

IN the current theories and experiments, the question whether a cosmic ray shower is produced in a single elementary process or rather in a succession of many elementary processes is still open to discussion. For example, the discussions of Geiger and Fünfer[1], and of Bhabha and Heitler[2] are based on the latter idea, while that of Heisenberg[3] represents the former point of view. In the first case, the shower contribution from different layers of producing material would be linear to its thickness, provided the latter is sufficiently small, while in the second case, on the contrary, a quadratic relation between the shower frequency and the thickness is to be expected.

Using the arrangement A of Fig. 1, in which at east three particles are necessary to cause a simultaneous discharge, Morgan and Nielsen[4], later

Watase and Kikuchi[5], have confirmed the quadratic increase in the initial portion of the Rossi curve, as it is shown by Curve *a*. In continuation of the investigations on this problem, Curves *b* and *c* are obtained by using the arrangements *B* and *C*. In case *B*, simultaneous discharges in four counters were recorded, while in case *C* those of five counters were registered. We see that the quadratic character becomes less prominent as the number of counters of which simultaneous discharges are counted increases.

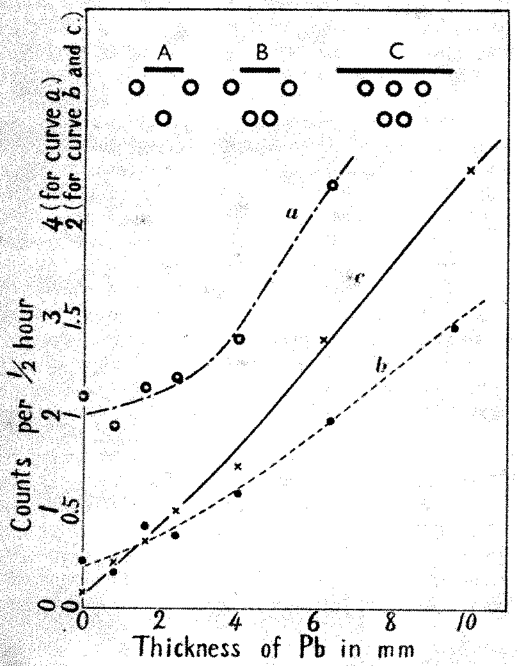

Fig. 1.

These facts show that a shower consisting of a large number of particles can be produced by a single elementary process. The quadratic character in the case of three counters may be explained by the existence of soft radiations of tertiary origin. As the efficiency of the counter for these radiations is much lower than for the direct secondaries, their contribution decreases very rapidly with the increasing number of discharges recorded simultaneously.

The present results do not exclude the existence of showers produced by a succession of elementary processes, but show clearly that the latter is not necessary for the production of a shower containing a large number of particles; or, in other words, there exists an elementary process in which many particles are produced simultaneously, as suggested by Heisenberg.

My thanks are due to Prof. S. Kikuchi for guidance throughout this work.

Action of Iron Oxide on the Emission Spectrum of Nitrogen-Mercury Systems excited by α-Rays

DURING a research on the synthesis of ammonia at room temperature under α-ray bombardment and in presence of Fe_3O_4, we have found that the gas surrounding the α-particle source emitted a relatively intense green glow. The α-particle source was radon in a small thin glass bulb, through the walls of which the α-particles could pass. The phenomenon is only observable when the iron oxide is reached by the α-rays, and has been bombarded for several hours in a stoichiometric atmosphere ($N_2 + 3H_2$). When a certain amount of iron oxide has been thus in some manner promoted, it remains active in subsequent experiments, even if between two experiments it has been brought into contact with air.

With pure nitrogen the green cold flame increases in intensity, hydrogen seeming to have a simple diluting effect. If radon is mixed with the stoichiometric gas, the glow is only to be seen in the neighbourhood of the magnetic oxide in a layer about one centimetre thick. On shaking, the luminosity spreads throughout the whole tube, and becomes brighter. When after shaking the tube is placed in a horizontal position, the light fades, starting from the end no longer containing the oxide and going towards the other end, until after some twenty minutes it is confined to a zone of one centimetre over the iron oxide. If the glow was emitted by iron oxide dust suspended in the gas, it would start settling in the higher part of the vessel and not on the end opposite to the oxide. The glow is thus to be ascribed to the gas phase.

The light was still visible with α-particle sources as weak as 3 millicuries. Increase of pressure and temperature intensifies the luminosity. Admission of even very small quantities of air by carefully opening the stopcock of the vessel was immediately followed by the extinction of the glow. The glow appears only in the space irradiated by the α-particles, and disappears within a small fraction of a second after irradiation.

Spectroscopic study gave us the nitrogen bands. Some of them (those marked with an asterisk) have already been observed by Sir William and Lady Huggins[1] or Himstead and Meyer[2], in the spectrum of the light emitted by a radium bromide crystal.

Second positive N_2 group	Group (NO)
*3159	2595·7
*3371	2722·2
*3577	2859·5
3805	*2977
4059	

Research was continued in two directions.

(1) The first working hypothesis was that the glow was similar to the green light produced in Strutt's experiments, when a current of active nitrogen met a current of nitric oxide, with formation of the peroxide. In the present case, nitric oxide could be formed by the action of bombarded Fe_3O_4 on excited nitrogen. All attempts to produce the green glow by bringing currents of nitric oxide and nitrogen in contact under α-ray bombardment have failed.

(2) The second hypothesis was that the phenomenon was associated with the presence of mercury vapour. Analogous green glows have been observed when mercury vapour in presence of foreign gases is illuminated by a mercury vapour lamp (Phillips[3], Wood[4], Donat[5]). What seems quite new in our case is the action of iron oxide. This hypothesis is backed

by observation of the increase of intensity (about thirty times) of the Hg line 2536·7 in presence of Fe_3O_4 bombarded by α-rays. Spectra in the visible region show an important increase of the visible triplet 5461, 4358, 4047, in presence of the iron oxide, and especially of the 5461 green line which is not visible at all when Fe_3O_4 is not present.

Eddy-Current Resistance in Fluids due to Rotation

THE well-known 'Larmor analogy' between the deflecting force exerted by a magnetic field upon the motion of electrically charged bodies and the 'Coriolis' force which similarly deflects a moving body relative to a rotating system of reference, suggested to me that the resistance to motion due to electrical eddy currents experienced by a conducting body rotating in a magnetic field should be paralleled when a rotating body of fluid is given a second rotation, for example, about a second non-parallel axis. The experiment, which was demonstrated at the recent meeting of the Australasian and New Zealand Association for the Advancement of Science in Auckland, N.Z., does, in fact, rather strikingly exemplify the gyro-magnetic analogy. A spherical vessel of metal or glass, filled with water and provided with an axle that turns in horizontal bearings and rotated (long enough for the water to take up the rotation) comes very rapidly to rest if set up on a rotating table—or even if the frame in which the bearings are set is turned while held in the hand.

With a glass bowl, the actual eddy currents in the water are made conspicuously visible by the movement of bubbles formed from the residual air when the bowl is not completely filled.

Fossil Pollen in Scottish Jurassic Coal

I HAVE recently made an examination of the microspore content of a sample of coal of Jurassic age that occurs at Brora, Sutherlandshire. The seam rests upon strata of the Estuarine Series (g^7), and has as its 'roof-bed' Kellaways Rock ($g^{\underline{10}}$). The seam proves to have a rich content of pollen, principally of genera of conifers belonging to the Abietineæ, but, in addition, it is interesting to record the presence of pollen of the types that characterize the Nymphæaceæ among the dicotyledons.

Water-lily pollen possesses certain characters that make recognition of the type easy. These characters are illustrated diagrammatically in Fig. 1, and may briefly be summarized as follows:

(1) A narrow furrow region (*f*), which in form is ring-shaped or open at one or both ends.

(2) A region, the operculum (*o*), enclosed by the furrow ring, in area always less than a hemisphere. The exine of the operculum may differ from that of the part of the grain outside the furrow ring in being distinctly thinner or differently ornamented (1,*d*).

(3) In the smoother *Castalia* species (1,*d*), the exine tapers in thickness towards the furrow ring, merging with the latter without a marked rim.

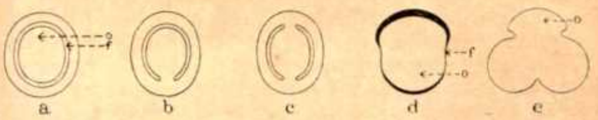

Fig. 1.

(4) In the genus *Nelumbium* (1,*e*) a third furrow is present, differing slightly in shape from those bounding the operculum. A very distinctive feature of *Nelumbium* pollen is that when viewed from the poles, the furrows do not divide the grain into three equal parts, as normally do the three furrows in other dicotyledonous types. In other words, bilateral, not trilateral, symmetry characterizes the *Nelumbium* type. As this distinction is probably a primitive feature, it may be expected to occur more frequently in fossil than in modern pollen types, and it should therefore be looked for in all work in fossil pollen, particularly the more ancient the material under examination.

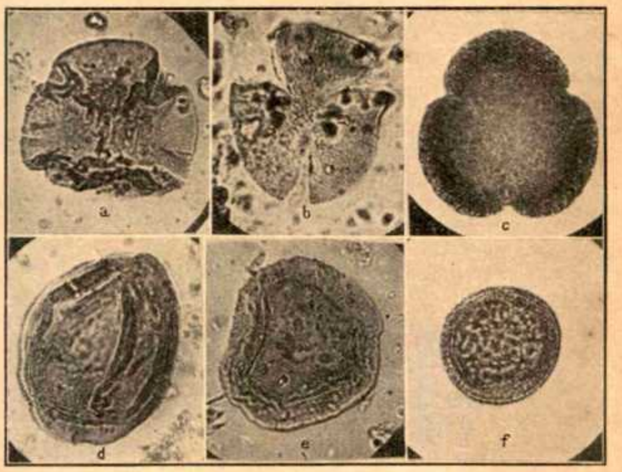

Fig. 2.

(*a*) *Nelumbium* TYPE, JURASSIC COAL, BRORA ; POLAR VIEW SHOWING OPECULAR FURROWS.

(*b*) *Nelumbium* sp., TERTIARY COAL, SCOTLAND, POLAR VIEW.

(*c*) *Nelumbium nuciferum* GAERTN., MODERN SPECIES.

(*d*) *Nelumbium* TYPE, JURASSIC COAL, BRORA ; LONGITUDINAL VIEW, SHOWING THIRD FURROW (CENTRE) AND OPERCULUM.

(*e*) *Castalia* TYPE, JURASSIC COAL, BRORA ; SHOWING OPERCULUM AND BOUNDING FURROWS.

(*f*) *Castalia crassifolia* HAND.-MAZZ., MODERN SPECIES ; OPERCULAR FURROWS ON EITHER SIDE.

ALL FIGURES × APPROX. 325 DIAMETERS.

As I think is evident from the photographs reproduced in Fig. 2, the water-lily pollen in the Brora coal already shows clear differentiation into the types characteristic of the modern genera *Nelumbium* and *Castalia*. Other genera of the Nymphæaceæ may also be present. Except for some forms possibly representing *Magnolia* and its allies, no other dicotyledons appear to be represented.

An *F*-Type Potato Virus in Australia

The *F*-type of potato virus recently described by Clinch, Loughnane and Murphy[1] and Murphy and Loughnane[2] is evidently widely distributed. At Canberra in January 1936 a virus which was carried without symptoms in a number of solanaceous hosts was recovered from potatoes with a slight aucuba mottling of the foliage. The variety of potato was supplied under the name Arran Crest, but its characters were rather those of Arran Pilot. No tuber necrosis was noticed. The virus was recovered a number of times over a period of a year from the tubers of these plants, and from second generation plants grown from the tubers. The presence of the virus did not protect the potato plants from infection with *Y*-type viruses, and various other hosts containing it were infected with *X* virus and $X + B$ without difficulty. It caused severe necrosis on pepper at mean temperatures below about 70° F.; above that, and at temperatures too low for the strong growth of pepper plants, the symptoms were milder. *Solanum nigrum* was found to be an important host on which the virus sometimes produced a very faint and transitory vein-clearing or mottle, but generally no symptoms at all. It could, however, be recovered from apparently unaffected plants in high concentration.

So far as they were studied, the properties of the Australian virus corresponded with those of the *F*-type. Whether this group is important in Australia is not yet known, although viruses causing necrosis of pepper have been recovered from several sources.

Interfertility Phenomena of the American and European Forms of *Panus stypticus* (Bull.) Fries*

Panus stypticus (Bull.) Fries is a small coriaceous agaric which grows usually on the wood of deciduous trees, and is found both in Europe and North America. Although alike morphologically, a striking difference exists between the American and European forms, namely, the former is luminous and the latter is non-luminous[1]. Since they were known to differ in this character, a study of the two forms in relation to their pairing reactions and the method of inheritance of the factor for luminosity was undertaken.

Monosporous mycelia were isolated from single fruit-bodies of *Panus stypticus* collected at Timagami, Ontario; Ottawa, Ontario; and Lake MacDonald, Quebec (in Canada); at Dresden, Darmstadt and Potsdam (in Germany); at Sigless in Austria; and at Wageningen in Holland. Series of pairings in all possible combinations of monosporous mycelia from each of these fruit-bodies have shown that both the American and European forms of this fungus are heterothallic and tetrapolar. These results were published in the Progress Report of the Dominion Botanist for the years 1931–34[2], and have been confirmed by Vandendries' work with the European form[3].

By pairing monosporous mycelia derived from different sources, it has been found that both the American forms and the European forms are fertile among themselves and that the American form is completely interfertile with the European form[3] (Fig. 1).

Fig. 1.

TABLE SHOWING THE RESULTS OF PAIRING EIGHT MONOSPOROUS MYCELIA OF THE LUMINOUS AMERICAN FORM OF *Panus stypticus*, +6004, AND EIGHT MONOSPOROUS MYCELIA OF THE NON-LUMINOUS EUROPEAN FORM, +5122. THE PLUS SIGN INDICATES THE PRESENCE OF CLAMP CONNEXIONS.

In sixty-eight pairings of monosporous mycelia of the luminous American form with the non-luminous European form, the diploid mycelium produced has been isolated and found to be luminous; that is, in the mycelium of the F_1 generation, luminosity is dominant. If sporophores are obtained from these paired cultures, the monosporous mycelia from them will be tested to determine the method of inheritance of the factor for luminosity in the F_2 generation.

Water and Fat Content of Tsetse Flies

In his recent letter to NATURE on this subject[1] Mr. R. W. Jack emphasizes the importance of excluding the weight of fat in tsetse flies when calculating the percentage of water found in them.

I came to the same conclusion early in 1935, and communicated my opinion to Prof. Buxton in a letter dated April 2 of that year. My complete findings for 1935, when more than 800 flies were examined by me, were published in 1936[2].

In Table 1 my results for 1935 are summarized. It will be observed that with increasing hunger the percentage of water in gross body weight shows a rise. But with fat eliminated from both wet and dry weights the percentage of water shows a slight fall after stage II of hunger, though the variation from stage to stage is now much less than before. The males, other than young males, are divisible into four stages of hunger by external characters—gorged, replete, intermediate and hungry.

Table 1 refers to flies (*Glossina morsitans*) collected in the field.

TABLE 1

Category	Fat, per cent of dry weight	Gross water per cent	Water, per cent of non-fatty weight
Males			
Stage I	25·87	62 19	69 55
Stage II	35 28	60 96	70·83
Stage III	24 53	63·62	69 89
Stage IV	14·56	64·77	68·43
Young	15·93	68 88	72 63
Females			
Mature	16·84	64 44	68 73
Young	15·25	68 92	72·36

Just-fed flies are normally inactive in Nature, but from laboratory experiments it is found that these contain nearly 75 per cent water in non-fatty body weight, the percentage of water in blood. By rapid excretion, water is eliminated immediately after feeding, up to 8 mgm. being removed in the first quarter of an hour.

The results are interpreted in the following way:

Fat is synthesized after feeding, and reaches a maximal proportion in stage II of hunger. Thereafter it diminishes until the next meal (stage III or stage IV). During the inactive period immediately after feeding the water content is depressed below the normal 70 per cent of fatless weight, and as it rises towards the normal, activity is resumed in late stage I. Thereafter the percentage is maintained close to 70 per cent, but falls slightly as hunger increases and loss of water can no longer be made good. It appears that death from 'starvation' occurs when the percentage falls to about 65 per cent.

In wild, young flies, for some unexplained reason, the percentage is higher at about 72½. My colleague, Mr. W. H. Potts, finds that in just-emerged individuals it is even higher.

To summarize the significant differences in the first and third numerical columns of Table 1, stage II is in each case significantly different from all the others. Stages I and III are indistinguishable from each other but, significantly different from the rest, except that in the third column the old females, because of high variance, are not quite distinguished from stage I males. Stage IV and all females and young males are indistinguishable as to fat percentage; in water percentage of fatless weight the young flies are distinct from all the others, but the sexes of young flies and of hungry males and old females are respectively indistinguishable. (Females taken in Nature are nearly always hungry.)

It is of interest that Buxton and Lewis[2] in Northern Nigeria found 63 per cent water in gross weight for wild male *G. submorsitans* and 60 per cent for wild females. These figures become 69 per cent in both cases when fat is eliminated from wet and dry weights. It is likely that some of these females were partly pregnant, as such flies have a higher fat content and therefore a lower percentage of water in the gross body weight.

Mr. Jack's point, that, when the proportion of water is so high, a small change in the ratio may indicate important losses, is well made.

Effect of Centrifuging on *Amœba proteus* (*Y*)

IN *Amœba proteus*, the cytoplasmic bodies are the nutritive spheres, crystals, neutral red bodies, mitochondria, sudanophil fat and a single contractile vacuole.

Fig. 1 illustrates the stratification of the various cytoplasmic components according to their specific gravity after centrifuging. Fat (*F*) and the contractile vacuole (*CV*) being the lightest, occupy the centripetal position. Next is clear cytoplasm (*C*), then the mitochondria (*M*) followed by a layer of neutral red bodies (*NR*), a layer of crystals (*CRY*) and the nutritive spheres (*NS*) which are the heaviest component of the cell and occupy the extreme centrifugal position. The nucleus (*N*) occupies a position in between the crystals and the nutritive spheres, and the chromatin (*CR*), being the heaviest material in the nucleus, collects towards the heavy side of the cell.

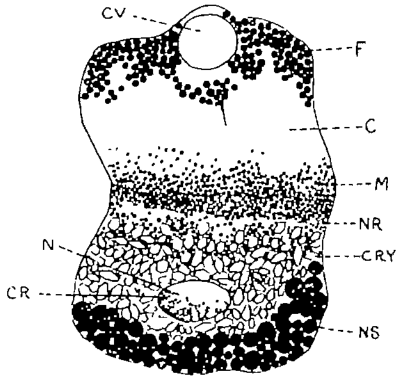

Fig. 1.

The nutritive spheres contain glycogen as a form of reserve food material. It is very interesting to note that no homologue of the Golgi apparatus appears to exist in *Amœba proteus*, and that the wall of the contractile vacuole does not blacken with osmic acid even after prolonged periods.

Excretion from Leguminous Root Nodules

VIRTANEN[1,2], using pea, vetch and clover, has amply confirmed the suspicion of some earlier workers by showing that under certain conditions (for example, in sand culture) there is an excretion of fixed nitrogen in the form of amino-acids from the nodules of these plants into the rooting medium. It does not follow that this finding may be extended to leguminous plants in general. In experiments carried out as an extension of published work[3], and with the assistance of Mr. I. W. Prentice, I have been unable, by analysis of the rooting medium, to find evidence of excretion of fixed nitrogen from the nodules of soya bean plants at any stage in development, although extensive fixation occurred within the nodules. The plants were grown in open sand-cultures, initially sterile.

These negative results may be due, not to the absence of excretion, but to (*a*) excretion being quickly followed by re-absorption by the roots, or to (*b*) the excreted substances in the soya bean differing from those in the types examined by Virtanen in that they are volatile—the sand was dried at 30°–40° C. prior to analysis. These two and other possibilities are being examined.

The earlier work of Stallings[4], who concluded that there is an excretion from soya bean nodules of ammonia, presumably in organic or inorganic combination, will be considered in a later fuller publication, together with other literature.

The Crayfordian and Boltonian Industries

THIS note refers to the nomenclature of the prehistoric flint industries found in (*a*) the basal gravel at Crayford and of the Ebbsfleet Channel, Kent, (*b*) the Upper and Lower floors in Bolton and Co.'s brickfield, Ipswich, and (*c*) similar floors in the subaerial loams of the Bean Valley and Ingress Vale, Kent. We propose in future to describe the specimens classified under (*a*) as *Crayfordian*, and those classified under (*b*) and (*c*) as *Boltonian*.

From a prolonged examination of the industries mentioned, we are satisfied that they cannot, without prejudice, be included in any of the ordinary subdivisions of prehistoric flint implements. Thus, the industries in question each includes Clactonian, Levalloisian, and hand-axe features, and it is not possible, therefore, to describe them by the usual nomenclature. The characteristics and geological age of these industries will be described before long, but we think it desirable that their new titles, which we hope will be generally adopted by archæologists, should be made public now.

We would point out that the specific names *Crayfordian* and *Boltonian* are based solely upon the characters of the flaked flints of the two industries, and do not connote any particular geological age for the specimens.

Magnetic and Electrical Dimensions

MY chief reason for desiring to reply to Prof. Howe's letter on this subject in NATURE of March 13 is that the last paragraph of the letter gives the impression, inadvertently I presume, that the implications of the adoption of Ampère's theory of magnetism had been considered fully by the International Committee when they made the recommendation that B and H were to be considered respectively in the roles of effect and cause, and their ratio μ therefore as an entity having physical dimensions. This is not the case.

Prof. Howe and I and all other members of the British Association Committee upon the subject were invited in 1934 to attend the meeting of the International Committee in London by the courtesy of the late Sir Richard Glazebrook, chairman of the International Committee. We were all made parties to the above recommendation, and at the time there seemed to be no alternative to an arbitrary resolution, although had we studied Maxwell's treatise more carefully we might have been more cautious.

It was not until January 19, 1935, that I showed in a letter to NATURE that the adoption of Ampère's theory opened up an alternative mathematical solution which makes μ undimensional, and I followed this by a paper to the British Association meeting at Norwich confirming this result and showing that I got complete support from Maxwell.

I have received a large correspondence about the conclusions of this paper. In September 1935 I received from Sir Richard Glazebrook a letter in which he writes: "To my mind Maxwell's theory, as developed in his book, is based on the two-fluid theory of magnetism. I have not considered how far the adoption of Ampère's theory, which no doubt is nearer the truth, modifies this but will consider the matter when I have a little leisure." It is greatly to be regretted that Sir Richard's untimely death deprived us of his considered opinion upon this important question.

From my correspondence with Prof. Howe, I can see that his main objection from the first to my conclusions has been the mathematical nature of the arguments. To my mind, the whole electrical science is the mathematical machine which he derides in his last letter, that wonderful machine which has produced the electromagnetic theory of light, to which is due the discovery of the quantum theory and all the other developments of modern theoretical physics. All that is fed into this machine consists of the empirical laws and the definitions of the various entities and constants. Now Prof. Howe would have us jettison the machine and the unit pole upon which several of our definitions are founded, and does not propose to provide us with equivalents. Even if equivalents were ready for adoption, is there any possibility of getting them adopted by the scientific world in the month or two before the fate of the dimensions of μ is decided?

Dealing with the purely physical character of μ, consider the coils of a wattmeter. If the current coil is energized, we get a magnetic field surrounding it, which we denote by H at every point. If now we energize the voltage coil, the nature of the magnetic field has not altered but only its magnitude and direction. If, on the other hand, we introduce a little piece of iron instead of energizing the voltage coil, this little piece of iron, according to Ampère's theory, consists of a multitude of atomic electrical circuits, each of which is equivalent to a voltage coil. In what respect does the physical nature of the magnetic field then differ from that which existed when the voltage coil was excited? According to the two-fluid theory of magnetism, they are different *in the iron*, but now that the two-fluid theory is discarded and there is only one medium to be considered, namely, empty space, is there any reason for maintaining the results of a discarded theory? According to Ampère's theory, B and H differ only in magnitude and direction, but are physically identical.

JAMES B. HENDERSON.

38 Blackheath Park,
London, S.E.3.
March 22.

IN his letter in NATURE of March 13, Prof. Howe avoids the very plain question put to him by Sir James Henderson. That question is: "What justification has he for writing $\mu \equiv 1/A'$?" The only suggestion put forward by Prof. Howe is that "the forces between magnetic poles and those between electric currents must involve the same property of space". But that condition is equally met by writing $\mu \equiv A'$—which is Henderson's proposal. In view of the strictures in Prof. Howe's review, it is clearly incumbent upon him to face this issue, and make his reasons for his choice as clear as those of Sir James; and I hope that he will do this.

WILLIAM CRAMP.

Points from Foregoing Letters

NEW experiments on the winter development of the gonads in the migratory finch, *Junco hyemalis*, under the influence of artificial illumination are described by Prof. Wm. Rowan. The author also submits photographs showing that starlings in the West End of London have in winter larger testes or ovaries than those in the country. He finds, however, that the light intensity at night, at the spot where the London birds roosted, was below that known to induce development of the sex organs, and he suggests that in this case the effect may be due to the noise which keeps the birds intermittently awake until the early hours of the morning.

The non-exponential and the exponential terms of the equilibrium constant and of the bimolecular rate constant of the reaction 2 *cyclo*pentadienes $\rightleftarrows$ di-*cyclo*pentadiene and of similar associations have been measured in the gas phase and in solution by Dr. G. A. Benford, Miss B. S. Khambata and Dr. A. Wassermann. They compare the solubility of *cyclo*pentadiene and of di*cyclo*pentadiene with the solubility of the *cyclo*pentadiene-*cyclo*pentadiene transition state.

Indirect support for Hallpike and Rawdon-Smith's membrane theory of origin of the cochlear component of the Wever and Bray effect has been btained by O. Gatty and Dr. A. F. Rawdon-Smith, who have shown that potential waves of similar haracteristics can be obtained from isolated strips f frog's skin, immersed in Ringer's solution. A type f artificial cochlea was constructed, and from this ynchronous potential changes were recorded, in esponse to sound.

W. Ross and E. C. Slow have measured the *phase elocity* of radio waves (of frequency 2·5–15 Mc. per econd) travelling along the ground, by observing the hape of the ellipse traced by an oscillograph to which vas applied the suitably amplified output from two imilar aerials placed a known distance apart. Though he observed values, for the phase velocity of the adio waves investigated, differ slightly from the elocity of light (possibly due to re-radiation from isturbing bodies near the receiving aerials), these ariations are small and without marked dependence pon frequency. The authors conclude that the *group elocity* of radio waves along the ground is also within few per cent of 3×10^{10} cm. per sec., which is not agreement with the findings of Colwell and his o-workers.

Curves showing 'coincidence' discharges in ounters' arranged in groups of three, four and five, ndicating the number of cosmic ray showers as fected by the thickness of the material (lead) in hich they are produced are submitted by Y. Watase. he curves obtained by means of the groups of four nd five counters are nearly straight lines, and show at some, at any rate, of the showers are produced y a single elementary process, as suggested by eisenberg. The curve obtained with three counters is of a quadratic type, which may mean that in some cases a succession of elementary processes is involved, or the quadratic character may be due to the presence of soft radiation of tertiary origin.

A. Luyckx reports that when nitrogen and iron oxide are simultaneously irradiated by α-rays, an intense green glow is emitted by the gas. Spectroscopic study shows that mercury lines are only observable in presence of nitrogen; iron oxide increases their intensity, and causes new mercury lines to appear.

A simple experiment showing how a rotating fluid comes rapidly to rest when given a second rotation non-parallel to the first, is described by Prof. Kerr Grant. The experiment was devised as an analogy to the resistance to motion, due to electrical eddy currents, experienced by a conducting body rotating in a magnetic field.

The '*F*-type' of potato virus recently isolated in Ireland has been found by J. G. Bald also in Australian potato plants with a slight 'aucuba' mottling of the foliage. The virus causes necroses on pepper. *Solanum nigrum* acts readily as host for the virus, showing no symptoms except an occasional transitory vein-clearing or mottle.

Panus stypticus (Bull.) Fries, as found in North America and in Europe, is shown by Miss Ruth Macrae to be heterothallic and tetrapolar. The two forms are fertile among themselves and with each other. When monosporous mycelia of the luminous American form and the non-luminous European form are paired, the diploid mycelium produced is luminous.

A table showing the water and fat percentage of tsetse flies of different ages and at different stages of hunger, is given by Dr. C. H. N. Jackson. The author had come independently to the same conclusion as R. W. Jack concerning the importance of excluding the weight of fat when calculating the percentage of water, and gives instances showing that the new way of calculating the water content gives more significant results.

Dr. G. Bond reports that analysis of the sand in which soya bean plants had been grown failed to give evidence of excretion of fixed nitrogen from the root nodules of the plants. Prof. Virtanen has shown that such excretion takes place in the case of peas, vetch and clover.

Sir James Henderson, continuing the discussion on the dimensions of electrical and magnetic concepts, points out that insufficient consideration was given by the International Committee in arriving at their decision concerning those factors. He reiterates his contention that taking Ampère's theory into consideration, the magnetic field *H*, and the magnetic flux *B*, differ only in magnitude and direction and are physically identical, so that their ratio μ, the magnetic permeability, is undimensional.

Research Items

Spirit Beliefs in Suriname

In the course of a detailed account of the folk-lore of the negroes of Suriname (Suriname Folk-lore: by Melville J. Herskovits and Frances S. Herskovits, *Columbia Univ. Contrib. Anthrop.*, 27), based on material collected in Dutch Guiana in 1928 and 1929, it is pointed out that the essential factor in the beliefs of the Paramaribo town negroes, is divination, for through the work of the diviner all the elements of their system are drawn together, explained and controlled. These elements are four in number: the *akra* or soul, the *winti* or the gods, *obia* and *wisi*, good and evil magic, and the spirits of the dead. *Winti*, the negroes say, means wind. It is in every place, and is the air we breathe. The spirit too is everywhere. The term defines the gods and spirits, which rule the universe; among the bush negroes gods are usually termed *gadŏ*, and in both city and among the bush negroes other terms are encountered. Although among the bush negroes a term for Supreme God frequently occurs, it is seldom that a sky-god is invoked in the town. The only reference is in the dance to the seven gods of the sky, the thunder gods. The earth gods are headed by the Earth Mother, who even in ritual is referred to by this euphemism, and is named correctly only in songs sung by those under possession. The Earth Mother has a large number of these 'strong' names, used only by initiates and in ritual performance. This variety of names may be due to the fact that the negroes are descendants of ancestors who hailed from very different parts of Africa. While other *winti* receive offerings only from their own devotees, the Earth Mother receives from all. The most prevalent type of *winti* among women are those associated with the snake. While some snake spirits may enter into possession of men, others possess women only. This seems to be connected with childbirth and the belief that ancestor spirits may make use of the snake. Other *winti* are connected with the river, or the bush, living in the ground, in trees and in holes. *Winti* may be acquired by inheritance, by choice of the spirit, or through the 'bad magic' of an enemy.

Expectation of Life in a Moth

MESSRS. RAYMOND PEARL and John R. Miner contributed a series of life tables for the pecan nut case-bearer moth (*Acrobasis caryœ*), of which a reprint has been received, to "Mélanges Paul Pelseneer" (*Mem. Musée Roy. d'Hist. Nat. Belgique*, ser. 2, fasc. 3; 1936). The details upon which the computations are based were taken from studies made on the insect by S. W. Bilsing and published in 1927. It appears that the proportional distribution of the imaginal life of the female moths into pre-reproductive, reproductive and post-reproductive phases, when compared with the equivalent divisions of the life of the human female, shows that the post-reproductive phase is substantially equally proportional in the two cases, while the *Acrobasis* female spends more than double the proportional amount of time in the pre-reproductive phase as compared with the human female. The mean duration of life of the moth shows an evident tendency to increase in the three successive generations after the first one. The female moths in all groups tend to be longer lived than the males by amounts that are probably significant. The relative variability in duration of life is roughly the same as that found in closely inbred strains of *Drosophila*. The above paper is part of a series of studies on life duration in the lower organisms: among insects complete life-tables have only as yet been calculated for the cockroach (*Blatta*) and *Drosophila*.

Root Systems

THERE is a general discussion of the technique of exposing and recording root systems by T. K. Pavlychenko in the *Canadian Journal of Research*, 15, No. 2, February 1937. This account describes much American work, but makes no mention of the studies of root systems of fruit trees carried out for some years at the East Malling Research Station, reports of which have been published in the *Journal of Pomology*. The author then describes the soil block washing method which has been developed at the University of Saskatchewan. All thorough methods of exposing and measuring root systems are of necessity laborious, and make big demands upon time and material; but this method, in which the roots are removed in soil blocks in specially constructed cases and then first soaked and freed from soil by constant gentle washing in a stream of water, must have been most successfully developed to judge from the photographs of root systems published. It is a little staggering to see the total length of the root system of a single wild oat plant, grown free from competition over a period of eighty days, estimated at fifty-four miles! The root systems of three-year-old plants of slender wheat grass, brome grass and crested wheat grass are estimated at 9·9, 65·2 an 315·4 miles respectively.

Necrotic Lesions of Virus Diseases

THE virus diseases known as tobacco mosaic and aucuba or yellow mosaic, produce local necrosis upor the leaves of *Nicotiana glutinosa*. Brown spots visible by the unaided eye, appear about two day after inoculation. A short paper by Dr. F. M. L Sheffield (*Ann. App. Biol.*, 23, No. 4, 752–758; 1936, traces the appearance of these areas where the tissu is killed. Necrotic material begins to form firs between the lower epidermis and the spongy parenchyma tissue of an infected leaf. It later extend upwards and outwards, until, about 72 hours afte inoculation, all the cells in the immediate neighbourhood are dead. The virus is isolated within th necrotic area. The outer cells of the necrotic regio are killed before the virus reaches them, and th virus cannot, apparently, traverse this dead tissue

Indian Lac Research

AMONG the investigations commenced in Februar 1930 at the Indian Lac Research Institute wer experiments which aimed at the improvement of th villagers' ordinary methods of exploiting the kusu tree (*Schleichera trijuga*) as a lac host (*Lac Researc Institute Bulletin*, Nos. 15 and 20. Criterion Printin Works, Jackson Lane, Calcutta, 1936). In Bull. 2

Mrs. Dorothy Norris, director of the Institute, discusses the success attained. By adopting the methods of pruning and cropping advocated, the kusum tree can be utilized in lac cultivation to much better advantage than under the rather crude methods of the Indian ryot (peasant). The hot weather crop (July) is known as *Jethwi* and the cold weather (February) as the *Kusmi* crop. The lines for the treatment of the tree were laid down in *Bull.* No. 15 and have proved highly successful. Trees pruned in February 1930 were ready for infection in February 1931, yielding a good crop of lac in July 1931, with a brood yield ratio of 1 : 3·1. A year later (the trees are rested for a year) in July 1932 the trees were again ready for infection and were cropped in February 1933, giving a brood ratio of 1 : 3·7. In February 1934 the trees were again ready for infection and gave a crop in July 1934 with a brood yield ratio of 1 : 3·2. In July 1935 the trees showed no sign of sickness or over-use, and were again infected and the crop, obtained in February 1936 was excellent in quality and gave a brood ratio of 1 : 3·1. It will be seen that these experiments were started six years ago only, and will require to be carried on for a much longer period to establish definite cropping figures; since so far only two *Jethwi* and two *Kusmi* crops have been compared.

The Arun River and Himalayan Uplift

THE Arun is one of those Indian rivers which rises north of the Himalayas and flows eastward, before turning southward and flowing through the Himalayas in a series of gorges between Mount Everest and Kangchenjunga. The theory that the river is an example of ordinary consequent drainage and that it has cut back and captured Tibetan drainage has been advocated by Hayden, Heron and others. The alternative explanation, that it is antecedent to the Himalayas and has maintained its course by vigorous erosion has also been suggested and is argued by Dr. L. R. Wager in a paper in the *Geographical Journal* of March. Dr. Wager pays particular attention to the remarkable Yo Ri gorge and the main gorge eleven miles lower down. In its upper course, the Arun flows over soft sedimentaries and forms a wide valley, but at the Yo Ri gorge it reaches hard gneiss in the Nyonno Ri anticline. This explains the change in form of the valley. West of the gorge lies the low pass of Kuyok La. Dr. Wager argues that if the original surface on which the Arun flowed had been anything like the present one, the river would have flowed through this pass. Since it did not do so, the Arun must have been established in its course before the present form of the land. The Tista River farther to the east probably shows a comparable history.

Temperature and Sunshine in the British Isles

Two interesting publications of the Meteorological Office have just appeared (London : H.M. Stationery Office). The first (No. 407) is entitled "Averages of Temperature for the British Isles" (1*s*. 3*d*. net), and the second (No. 408) "Averages of Bright Sunshine for the British Isles" (1*s*. net). In each case, the averages refer to periods ending in 1935, and are for individual months and the whole year. These averages correspond to some extent with the old 'normals', which were averages for a period, 1881–1915, which was assumed to be a whole Brückner cycle of weather, the length of which cycle was taken to be 35 years. As such a small part of our weather vagaries are consistent with such a cycle, it is doubtful whether very much is gained by using 35-year averages as representative of normal conditions. There is much to be said besides for having averages, such as these new averages, which do not include years like the early 'nineties, when the old-fashioned kind of winter with weeks of skating turned up fairly regularly each year. It is hard to give a satisfying definition of a 'normal'. If it is based on a short period, it will be objected to as too small a statistical sample. If the period is made very long, other critics will say that our climate has altered since the earlier years of the long period. Yet standards of reference of some kind seem necessary. For example, unless official forecasts give the actual range of temperature that is expected, which can scarcely be hoped for when places at different heights and different distances from the sea have to be grouped into a single 'district', the forecaster has to use expressions like 'cold' or 'rather cold', and these mean cold compared with the normal for the season. Those members of the public who want to know precisely what is implied must have averages of the kind given in these two booklets.

Viscosity of Air

G. KELLSTRÖM (*Phil. Mag.*, March) has made a new determination of the viscosity of air, using the viscous drag between concentric rotating cylinders. The mean value for the viscosity at 20° C. was found to be 18200×10^{-8} C.G.S. units. This value is about 0·7 per cent higher than the one used by Millikan in his determination of the electronic charge by the oil-drop method, and a substitution of the new value in Millikan's work raises the value of e from $4{\cdot}770 \times 10^{-10}$ to $4{\cdot}818 \times 10^{-10}$ E.S.U. The error in the viscosity data may therefore account for the difference between the oil-drop value of e and that obtained from absolute wave-length measurements of X-rays, namely, $4{\cdot}805 \times 10^{-10}$ E.S.U. (cf. NATURE 137, 655; 1936).

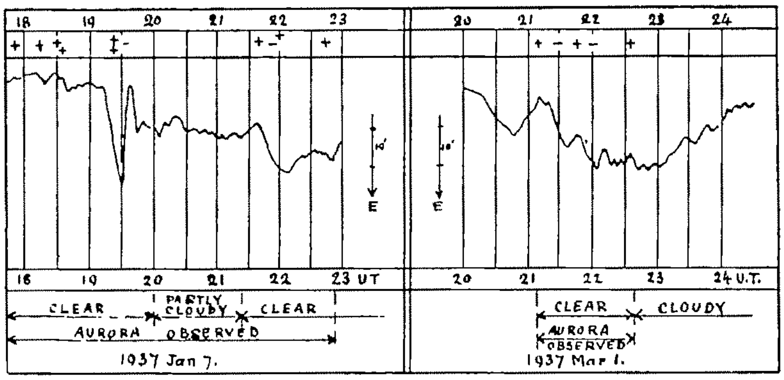
The Mysterious Number 137 Again

As mentioned in NATURE of May 23, 1936, p. 877, Euler and Kockel, working on a form of Born's unitary field theory, obtained the value 82·4 for the dimensionless pure number the explanation of which Born has declared to be the central problem of natural philosophy. An estimate of 130, which is much closer to the experimental value 137·2, has now been obtained by L. Infeld (*Proc. Camb. Phil. Soc.*, 33, 70; 1937) by using a different action function. It is shown that most of the consequences of the unitary field theory at first developed by Born and Infeld hold good for a whole range of action functions, all giving a static solution with central symmetry and finite energy, both for the electric and magnetic field, and reducing to Maxwell's action function for weak fields. That chosen by Born was distinguished by perfect symmetry between the electric and the magnetic field. A paper, not yet published, by Infeld and B. Hoffman will lay down a physical criterion to determine which function should be chosen. An even wider generalization of part of Born's electrodynamics has been made by P. Weiss (*ibid.*, 33, 79; 1937), who shows that every self-conjugate analytic function of a complex variable characterizes an electrodynamic field theory of the type proposed by Born. More stringent physical conditions, not yet available, are needed to thin out this over-luxuriant growth.

The Solar and Magnetic Conditions Associated with Recent Auroras

By the Rev. J. P. Rowland, S.J.

As already noted in NATURE (Feb. 13, 20 and 27), notable displays of the aurora were observed on January 7 and February 3, and it was anticipated there might be a recurrence after the 27-day interval of solar rotation on March 2. Weather was generally cloudy or overcast and unfavourable for observation on the last-mentioned date, but Mr. W. N. Craig, of Fortrose, Ross-shire, writes that an observer near Cambridge reported seeing the aurora between 20h. and 21h., with a maximum brightness at 20h. 45m. U.T., and another observer at South Queensferry, near Edinburgh, in a small clearing at 19h. 45m., noted the sky to be brighter than usual. Two persons near Stonyhurst, in a brief partial clearing of the sky, reported seeing auroral rays between 20h. 20m. and 20h. 30m., and an observer in the vicinity of Preston noted indications of aurora with rays, between 23h. and 23h. 25m. On the other hand, Mr. W. B. Housman, director of the Aurora Section of the British Astronomical Association, observing over the Solway Firth from Seaton, Cumberland, reports: "On March 2nd there was no aurora seen throughout a cloudless night here, observations being at very frequent intervals". On the Stonyhurst magnetic traces there was a moderate magnetic disturbance from 18h. 40m. to 19h. 40m., after which conditions were quiet, with only very slight movements.



On March 1, however, a prolonged and bright quiescent aurora was observed at Stonyhurst, from 20h. 45m. to 23h. 30m., which was especially bright between 21h. 30m. and 23h., extending to an altitude of 35° or 40°, gradually fading away to a slight glow by 23h. 30m. when observation ended. This aurora, and that of January 7, were observed in great detail by Mr. Housman at Seaton, and from a correlation of his log with the Stonyhurst magnetic declination traces, some interesting inferences may be drawn. This correlation, as made by Mr. Housman, is shown in the diagram above; the signs + and − above the declination trace, indicate respectively when a homogeneous arch was in being at the time indicated, and when the arch dissolved into streamers and luminous activity. The sign ‡ indicates the existence of a double arch, during the large easterly deflection of the magnet between 19h. 15m. and 19h. 30m. on January 7.

As Mr. Housman points out, it appears that in general the arch forms during an easterly swing of the magnet, and dissolves into an outburst of streamers and other luminous effects at or near the end of the easterly swing. It also appears from these observations, that auroral features may be seen when there is very little disturbance of the magnets, though a greater disturbance accompanies a more vivid display, as on February 3.

Mr. Craig mentions an aurora seen in Maine, U.S.A., "in the middle of December", but as no date is given, it is not possible to correlate this with the magnetic conditions, which were, in fact, remarkably quiet throughout the month, with the exception of a moderate disturbance on December 27 and 28. The auroral display of October 16, 1936, discussed by Prof. Vegard in NATURE of November 28 (p. 930), was accompanied by a very notable magnetic disturbance, lasting from October 16d. 15h. to 17d. 7h., with oscillations in declination of 28′ between 18h. and 20h., a rapid easterly deflection of 23′ at 22h. 30m., and a range of 39′ over the whole disturbance.

When we come to consider the relation of these phenomena to solar activity, we are on less sure ground. According to generally accepted theory, both auroras and magnetic disturbances are attributable to the emission of streams of corpuscles from disturbed areas on the sun, which travelling with high velocity under the action of radiation pressure enter the earth's upper atmosphere, and there set up ionization currents and electrical discharges in the rarefied gases, which manifest themselves in the disturbance of the earth's magnetic field, and the glows of the auroral light. The frequency of both auroras and magnetic storms, and the mean annual magnetic ranges, show a close correlation with the 11-year sunspot cycle, and both show a recurrence tendency after 27-day intervals, corresponding to the mean solar rotation period.

When we come, however, to the consideration of individual correspondences, the position is not so clear. There are cases where large sunspots cross the disk without any obviously corresponding magnetic disturbance, and conversely, magnetic disturbances occur when there are no spots on the sun. It should be remembered that sunspots are not the only manifestation of solar activity, and magnetic disturbances may be associated with the presence of faculæ, bright or dark flocculi, and eruptions on the disk, which, at the limb, would be seen as prominences. In the case of magnetic disturbances which are apparently associated with individual spots, statistical investigations show that the magnetic disturbance may occur from 1–2 days before to 3–4 days after the central meridian passage of the spot, corresponding to mean corpuscular velocities of 1,100–270 miles per second.

There is good ground for believing that the recent auroras and accompanying magnetic disturbances were due to the activity of a region of the sun centred in approximately lat. 10° S., long. 200°. In this area, the centre of an enormous spot group, extending over 8° in latitude and 16° in longitude, crossed the sun's central meridian within 4° of the centre of the disk at approximately midnight of January 30–31. It was therefore in a most effective position for a roughly radial stream of corpuscles to be intercepted by the earth, and the magnetic disturbance and aurora of February 3 must be attributed to it. The same region crossed the central meridian on January 3 and February 26, in each case showing a spot of moderate size, the times of central meridian passage being Jan. 3d. 9h. and Feb. 26d. 18h. respectively, and it is reasonable to suppose that the phenomena of January 7 and March 2 were associated with this area. The aurora and magnetic disturbance of March 1 were probably not associated with this area, but with a small group of spots in lat. 11° S., long. 228°, which crossed the central meridian on Feb. 25d. 0h. If these inferences are correct, the time intervals between the central meridian passages of the spots and the respective auroras, and the deduced corpuscular velocities are as follows :

Date of Aurora.	Time Interval.	Corpuscular Velocity.
Jan. 7.	4d. 10h.	250 miles per sec.
Feb. 3	4d. 19h.	220 ,, ,, ,,
Mar 1.	4d. 22h.	217 ,, ,, ,,
Mar. 2.	4d. 0h.	280 ,, ,, ,,

On February 25 there was an extensive belt of spot groups stretching almost across the disk in the northern hemisphere of the sun, but as there was no corresponding sustained magnetic disturbance, these groups appear to have been magnetically comparatively inactive, probably on account of their distance from the centre of the disk, which averaged about 20°. A large naked-eye spot in lat. 9° N. crossed the central meridian on March 2d. 0h., but it is unlikely that this was associated with the aurora on that day or the previous one, both on account of the lack of the requisite time interval, and because, owing to the backward tilt of the sun's axis, it was 16° from the centre of the disk, where it would be less effective. It may, however, have been responsible for a moderate magnetic disturbance on March 5.

Mr. Craig suggests that the aurora of October 16, 1936, may belong to the same series as the recent displays, but this seems unlikely, as it would involve a mean interval of 27·5 days, corresponding to the solar rotation period in latitude 20°, whereas the spots involved in the recent cases had a latitude of 10°, with a rotation period of 27·05 days. A spot of appreciable size in lat. 12° S., long. 225° crossed the central meridian on October 11·8, and may have been responsible for the aurora and magnetic storm of October 16. As this position is very nearly the same as that of the group which has been suggested above as probably responsible for the display of March 1, it would appear that these two occurrences may be considered as belonging to a separate series different from that of the displays of January 7, February 3 and March 2. This case, however, illustrates the difficulty of assigning individual correspondence between solar and terrestrial phenomena, for on October 12 a sporadic group of small spots crossed the central meridian in lat. 18° N., which, owing to the forward tilt of the sun's axis at that time, was only 12° from the centre of the disk, and therefore in a more favourable position to produce terrestrial effects than the southern spot, the distance of which from the centre was 18°.

With the approach to the time of sunspot maximum, conditions for the production of the aurora are likely to be frequent during the next two years, but owing to the decreasing hours of darkness, conditions for observing the displays will not be favourable until next autumn or winter, when it is to be expected many displays may be seen.

The Development Commission

THE twenty-sixth report* of the Development Commissioners, covering the year ended March 31, 1936, reviews the expenditure from the Development Fund on agricultural and rural economy, fisheries, the construction and improvement of harbours and on the acquisition of land for road improvements. Advances recommended from the Fund amounted to £555,201 on agricultural and rural industries and £85,925 on fisheries as against £402,859 and £88,109, respectively, in 1934–35. For the maintenance of agricultural research, advisory services for farmers, experiments on field crops and livestock and the provision of buildings and equipment £421,762 was advanced as against £361,691 in 1934–35. Of this, £285,984 was advanced to the Ministry of Agriculture and Fisheries, £67,101 to the Department of Agriculture of Scotland and £16,982 to the Agricultural Research Council, in addition to £43,000 to the latter Council for capital expenditure. The advances to the two Agricultural Departments include £198,170 for maintenance grants to Research Institutes in England and Wales and £40,966 for those in Scotland. The total provision recommended during the year for research and advisory activities in agriculture in Great Britain amounted to £369,977, a generous figure in comparison with State assistance to other industries, although even at this figure research expenditure only amounts to about 0·14 per cent of the value of the year's output.

For the first time since 1931 a considerable sum was approved for the erection of new buildings at institutions engaged in research or agricultural education. Grants have been approved for this purpose to the Studley College for Women, the Royal Agricultural College, Cirencester, the University College of North Wales, Bangor, the Midland Agricultural College, the Avoncroft Agricultural College, and the Royal (Dick) Veterinary College, Edinburgh. Assistance given to rural industries has three principal aims : the provision of technical advice for craftsmen by the Rural Industries Bureaux ; the interest of local residents, usually members of Rural Community Councils, in the welfare of village craftsmen; and the employment by Rural Community Councils of a Rural Industries Organizer. Details of the work of the Rural Community Councils and of the Rural Industries Bureaux are included in the report.

---

* Development Commission. Twenty-sixth Report of the Development Commissioners, being for the Year ended the 31st March 1936. Pp. 184. (London: H.M. Stationery Office, 1937.) 3s. net.

Although the Commissioners are not directly concerned with the provision of work for the unemployed, assistance has been given to two admirable schemes relating to land cultivation—the Allotment Scheme of the Society of Friends and Central Allotments Committee and the Land Settlement Association. Stress is laid upon the experimental character of these schemes for converting the unemployed industrial worker into an independent landholder and on the need for organization in this field if our natural resources are to be used to full advantage. Assistance has also been given to the Agricultural Camps Committee.

While the agricultural section of the report is concerned only with administrative matters, the section on fisheries includes an account of work reviewed by the Commissioners' advisory committee on fishery research as well as progress reports submitted by the directors of institutions receiving grants in aid of fishery investigations. The difficult situation at Armstrong College, Newcastle-upon-Tyne and the Dove Marine Laboratory, Cullercoats, since the financial emergency of 1931, due to the fact that the staff were partly engaged in 'directed' research on the local herring fishery and on pollution in the Tyne for the Ministry of Agriculture and Fisheries, for which the Minister's vote was drastically reduced, has been met by initiating a new grant period of five years in the form of a single block grant towards the total maintenance expenses of the Laboratory. Tribute is paid to Prof. Hobson's determination and ability in overcoming the difficulties and re-organizing research and to the value of the Laboratory in supplementing the fishery researches of the Ministry. Continued support of Prof. A. C. Hardy's investigations at University College, Hull, on the influence of plankton on fisheries is recommended; and reference is made to the development at Conway through investigations on shellfish of a cleansing process for mussels which eliminates the danger of carrying typhoid, and this process has been adapted to the purification of oysters. Other investigations in this field are concerned with the reliability of bacteriological methods for the routine testing of shellfish for sale, and grants have also been given for the development of freshwater fisheries, including investigations of salmon and sea-trout.

Grants for fishery research are made from the Development Fund either to the Fishery Department for 'directed' researches on problems immediately affecting the economic development and exploitation of fisheries, or to universities, colleges and marine laboratories for 'free' research, with the object of increasing our knowledge of the animal and plant life of the sea in relation to its whole environment. In the first category fall the important investigations on the difficult problems connected with herring fisheries, which differ for England and for Scotland. In Scottish waters the Fishery Board's investigations have shown that the shoaling of the herring on the drift-net grounds in early summer is associated with the search by groups of fish from different sources and of different types for the rich food-plankton then present in northern waters. In the great autumn fishery off Yarmouth and Lowestoft, however, the fish are on a migration preliminary to spawning and the shoals are not feeding. The investigations of the English Fishery Department have led to the issue of much more accurate forecasts of this autumn fishery. Other directed investigations have been concerned with inshore fisheries such as the population of small plaice in sand bays on the east coast of Scotland with a view to determining how far the stock needs protection by regulation of fishing. Diseases of freshwater fish, such as furunculosis, have also been studied, while among the 'free' researches assisted may be mentioned Dr. H. B. Moore's investigations on animal and plant life of the seashore, the cause of the dying out of eel-grass or grass-wrack and on artificial hatching and stocking of salmon fisheries.

Enough has been said, however, to indicate the wide range and importance of the Development Commissioners' contribution to scientific research. Equally it would seem that the Development Fund contains possibilities of co-ordinating the national effort in research, which might well be applied in very much wider fields.

The Chemist in Industry

THE Society of Chemical Industry concerns itself very largely with the practical application of chemistry, and in the main operates through its subsidiary groups, of which there are four, and its numerous sections in Great Britain, in the Dominions and in the United States. Once a year, at the annual general meeting, the Society as a whole meets at the headquarters of one of the sections and like the British Association it visits the Dominions and the United States from time to time. This year the annual meeting will be held at Harrogate, though Leeds is the headquarters of the Yorkshire Section, and next year the meeting will be in Canada. At these meetings the business of the Society is dealt with, addresses are delivered, a few papers are read, works and places of interest are visited, but the social atmosphere predominates.

About a year ago, however, the Council came to the conclusion that some matters of general interest to chemists and the chemical industry as a whole could only be dealt with at conferences specially convened, and accordingly it appointed a strong committee with Dr. Wm. Cullen as convenor to give effect to its decisions. The Manchester Section was anxious that the first conference should be held there, and no more appropriate place could have been chosen.

As the subject chosen for the symposium held on April 2, namely, "The Chemist in Industry", was somewhat wide, and indeed vague, it was decided that there should be two sessions, one in the afternoon and the other in the evening, at which sub-divisions of the general subject should be discussed. The subject of the afternoon session was the "Induction and Functions of the Chemist", and that of the evening session, "His Influence and Reward".

Eight short papers were prepared and all were published in advance of the meeting in *Chemistry and Industry*. In addition, reprints were available at the meeting. Two *rapporteurs* were appointed to summarize the papers, namely, Dr. R. H. Pickard, director of the Shirley Institute, for the afternoon session, and Mr. C. J. T. Cronshaw, managing director of the British Dyestuffs Corporation, for the evening session. In the unavoidable absence of Lord Leverhulme, president of the Society, Mr. W. A. S. Calder, a past president, presided over the conference.

By adopting this arrangement, practically the whole of the time available was devoted to the discussions, and it may be said that the speeches on the whole were excellent. The immediate point under discussion was seldom lost sight of, and so far as the first session is concerned, it looks as if the Committee would be in a position to come to definite conclusions which it is hoped will be helpful to the universities and colleges on one hand and industry on the other. As might have been expected, the discussions centring around the subject for the evening session were less helpful, but inspiring nevertheless.

No attempt will be made to summarize these discussions here. In due course they will no doubt be published, together with the conclusions of the Committee, but it is quite clear that the symposium has justified itself, and others will no doubt follow in due course.

The following is a list of the writers of the papers, all of whom were requested to confine themselves, so far as possible, to their own experiences: *Afternoon Session*: Dr. J. J. Fox (Government Chemist); Prof. J. C. Philip (Imperial College of Science and Technology); Mr. F. Scholefield (College of Technology, Manchester); Mr. C. M. Whittaker (Courtaulds, Ltd.). *Evening Session*: Mr. H. Ballantyne (Lever Bros., Ltd.); Mr. G. E. Collins (Shirley Institute); Dr. A. E. Dunstan (Anglo-Iranian Oil Co., Ltd.); Mr. J. Rogers (Imperial Chemical Industries, Ltd.).

It will be observed that the writers of these papers covered a very wide field, from both the academic and industrial points of view, and though the whole field could not be covered, this defect was remedied largely by the discussion in which twenty-five persons, all men of standing, took part.

It is just as impossible to summarize the papers as the discussion, but one or two points have emerged:

(a) For certain classes of work, graduate chemists do not appear to be sufficiently trained in manipulative technique, possibly through the attempt to put too much into the curriculum.

(b) There has been too little contact between industry and the teaching institutions generally.

(c) There is a large demand for chemists whose training from the start is along definitely technical, as opposed to purely academic, lines.

(d) For success in other walks of life, such as administration, business, salesmanship, and even finance, chemical training forms just as good a background as any other.

Probably the most striking statement made during the symposium was by Mr. C. M. Whittaker, who said: "In my experience there are just as many fools walking about with high academic qualifications as there are able men walking about with lesser academic qualifications, but of greater ability and deserving of greater financial reward."

In this connexion the views of many of the speakers, which seemed to be endorsed by the very large audiences present, were that the avenues to inclusion in the profession should not be closed in the slightest degree to those who had the desire to better themselves.

Forestry in the Gold Coast

THE annual report of the Forestry Department of the Gold Coast for the year 1935–36 (Accra: Govt. Printing Dept., 1936) by Mr. R. C. Marshall, conservator of forests, is written in non-technical language and gives evidence of progress in the introduction of a sound forest administration.

Cocoa forms one of the staple exports of the Colony, and the protection of a certain area of forests in the right situations is indispensable to this industry. It has been established by the research work carried out under the Cocoa Research Scheme at the Imperial College of Tropical Agriculture in Trinidad that an even moisture status is one of the characteristics of a good cocoa soil, and environmental studies have demonstrated that the moisture status of both soil and atmosphere have important bearings on crop productivity. The chief function of shade trees in cocoa cultivation is to provide a buffer against fluctuations in environmental conditions. This lesson was learnt many years ago in Madras and Ceylon in connexion with coffee and the tea gardens and other forms of planting cultivations. The clearing of large blocks of forest and the hacking which took place in those remaining in the neighbourhood led to serious erosion, desiccation of the soil and so forth; this led to heavy losses and considerable areas going out of cultivation. If the conditions in the Gold Coast are to be adequately preserved, where such preservation is not altogether too late, "the requirements of this industry need to be considered from time to time by the Forest Agricultural Departments in collaboration with the Administration".

Mr. Marshall considers three types of protection forest reserves as required in the Colony: (a) headwater reserves, (b) barrier reserves, and (c) shelterbelt reserves. It is said that reservation has been so far concentrated on (a) the protection of headwaters and (b) the barrier reserves situated between the edge of the closed forest zone where it marches with the drier open (savannah) forest; the idea being to stay the encroachment of dry conditions. During the year, the chief attention has been paid to what are termed (c) the shelterbelt reserves. These latter are to be oriented so far as possible at right angles to the prevailing wind and spaced at intervals through the countryside: their function is to protect agricultural cultivation, especially cocoa; to assist in maintaining the necessary environment of a closed forest climate, and to afford additional lines of defence against the encroachment of open-forest conditions. How far this aspiration will be possible in view of the considerable area of forest which has already been swept away or reduced to a condition in which it will prove useless for the purpose in view it is impossible as yet to say. But this matter has not been taken up any too soon.

It is apparent from the report that the Conservator has been able to increase considerably his gazetted staff (from 12 in 1934 to 18 in 1936) and is making progress in an even more desirable matter—that is, in "bringing the Forest Department district organization into line with the political district organization which itself follows tribal distribution as far as possible. At present forest districts consist of two to three political districts".

With a strengthened staff, the Conservator rightly decided that the first work to deal with was the selection, demarcation and cultivation of the forest reserves still demanding constitution, and a considerable amount of work in this connexion was undertaken during the year.

With the sub-division of the country into definit forest districts, each to be in charge of an assistan conservator of forests, the management of the fores districts will receive more attention and the advanc in the introduction of working plans will prov feasible, when sufficient stock mapping of the growin stock in the forests has been accomplished.

Fuel will be required so far as can be foreseen i increasing amounts in the Colony, both for domest consumption and for power in connexion with wate work schemes. The exotics *Cassia siamea* and th Indian neem are both giving satisfactory results, e elsewhere in West Africa. Good fuel wood is succes fully produced in seven years or less. The total are of fuel plantations amounts to 1,000 acres, th greatest area at Achimota, where the highly successf School is situated, within a short distance of Accr the capital on the Coast. Other plantations of th same type exist at Cape Coast, Kumasi and oth centres. Assistance is also given by the Departmen in connexion with water-works schemes. The su tained supply of fuel to the mines is proving a mor difficult matter.

The report has some interesting remarks on th subject of the prevalent practice of firing the sc called open or savannah forest lands and shiftin cultivation. It is the most informative forest repor on the Colony which has appeared for some time.

Oak-galls in Theophrastus

PROF. GUSTAV SENN, of Basle, has published a short but interesting note on this subject (*Verh. Schweiz. Naturforschende Gesellschaft*, Solothurn, p. 372; 1936). Theophrastus mentions, in his "Historia Plantarum", no less than ten species of oak-galls. Some are well known and unmistakable, such as the common Turkey or Aleppo gall; and one, or the insect which produces it, *Andricus Theophrasteus*, bears the old Greek's name. But no one seems ever to have studied the Theophrastean account as a whole, and even Sir Arthur Hort made no attempt to identify the several species. Prof. Senn finds little difficulty in doing so, and the result is a remarkable testimony to Theophrastus's diagnostic skill.

The 'little gall' with which the account begins (H.P., 3, 7, 4) is the valuable Aleppo gall, or 'ink marble', formed by *Cynips tinctoria*. The common 'black resinous' gall is the Bassorah gall, made by *C. insana*; it is the only one with a coat of resin. A scarce one, very hard in texture, mulberry-like in form, is identified by Prof. Senn as the gall of *C. culiciformis*. Another, phalliform in shape, growing into something like a bull's head at one end and with a hard interior like an olive-stone, is identified as the gall of *C. Quercus-Tozæ*. Fluffy balls, serving for lamp-wicks, are the woolly or cotton galls of *Andricus Theophrasteus*, akin I suppose to *A. ramuli*; and other hairy or bristly galls, covered with sweet honey-drops in spring, but quite useless, are those of *A. lucidus*. Certain stalkless galls, looking like a cluster of leaf-scales and growing in the axil of a leaf or twig, are the hop galls or artichoke galls of *A. fecundator*. The rare, elongated, close-textured foliaceous balls are the galls of *A. multiplicatus*; and, last of this catalogue, the clear juicy globules, grow ing on the midrib of a leaf, are the well-know currant galls of *Neuroterus baccarum*.

In another passage (H.P., 3, 3, 8), Theophrast mentions, with the same brief accuracy, the gall which the tanner uses and the black ones whic serve for the dyeing of wool; these being, onc again, the Aleppo galls of *C. tinctoria* and the Bassora galls of *C. insana*. A little gall, something like th Aleppo gall but smoother, and of no commerci value, is in all probability the oak-marble, or oa apple, of *C. Kollari*. Connold, in his "British Oa galls" says of it: "*C. tinctoria* bears a very clo resemblance to *C. Kollari*, and many specimens o the latter might easily be mistaken for the Alepp gall"; but the latter, he adds, yields 40 per cent tannin, while *C. Kollari* gives only 17 per cent. Th last identification may be a little doubtful, but th other nine oak-galls mentioned and characterize in a word or two by Theophrastus are easily an safely identified. The fact is that, great philosoph biologist as Aristotle was, Theophrastus was f ahead of him as an observer and recorder of speci from a modern botanist's point of view.

Sir Thomas Browne, in his notes on the "Natur History of Norfolk" (ed. T. Southwell, 1902 found on the oak just about as many galls a Theophrastus knew, and characterized them wit equal skill. His "*Juli pilulæ*, little balls on th flower catkins", are a form of the currant gall his *excrementum lanatum* is a woolly gall; an his *capitula squamea jaceæ æmula*, "little scaly hea like the heads of knapweed", are without doubt o hop or artichoke galls.

Science News a Century Ago

Heathcoat's Steam Plough

IN the *Gentleman's Magazine* of 1837, under the date April 18, it is said: "A deputation named by the Highland and Agricultural Society of Scotland met at Red Moss, near Bolton, according to appointment, to inspect the steam plough invented by Mr. Heathcoat, M.P. for Tiverton, and working under the direction of Mr. Parkes, Engineer. The deputation was composed of the Marquess of Tweeddale, Vice-President, Sir John S. Forbes, Mr. Oliphant, M.P., and other Members, with Mr. Gordon the Secretary. The machine has been made by Mr. Heathcoat, to operate in the first instance on moss, in which it is very efficient. The engine is of 15 horse-power, and the plough is attached by a band of the width of about two inches. The length of the furrow in the ground operated upon was 304 yards, breadth 18 inches and depth 9 inches. The furrows were cut on an average in four minutes and a half, which is equal to about half an acre turned over by the hour. The deputation, and many other gentlemen present, from different parts of the United Kingdom, expressed themselves highly gratified by the efficiency of the machinery."

John Heathcoat (1783–1861) was famous as the inventor of lace-making machines, and had a mill at Loughborough which was destroyed during the Luddite riots of 1816. After this, he removed to Devonshire and in 1832–59 represented Tiverton in Parliament. His plough was patented in 1832.

Natural History Collections from New Zealand

IN *The Times* of April 19, 1837, is the following note from a correspondent: "It will, perhaps, not be uninteresting to your readers who are lovers of natural history to know that the bark *Guiana* arrived this morning from Van Dieman's Land, on board which is a young naturalist (whose name I did not learn) who has been out to Van Dieman's Land and New Zealand, collecting in the various branches of natural history. I was favoured with a sight of his splendid collection of insects, shells and bird skins; but more particularly with three fine living opossums, one of which is white, the only one which has left its native woods. As they are to be deposited for a short time in the Surrey Zoological Gardens, previous to their removal to the country, this paragraph in your valuable and widely circulated paper will give many naturalists an opportunity of seeing them previous to their removal. I also saw a box containing from 400 to 500 roots, of the curious and splendid terrestrial orchidiæ of the above countries, many of which are new and will be a grand acquisition to our gardens; they are valued at the sum of £700."

David Douglas's Observations in America

WHEN David Douglas (1798–1834), a Scottish botanical collector, was killed in the Sandwich slands, he left various manuscripts which ultimately ame into the hands of Major (afterwards General Sir) Edward Sabine (1788–1883), brother of Joseph Sabine (1770–1837), secretary of the Horticultural Society, to whom Douglas had been recommended by Sir W. J. Hooker. The manuscripts consisted of several volumes of lunar, chronometrical, magnetic, meteorological and geographical observations, and these formed the subject of a paper entitled "Observations taken on the Western Coast of North America by the late Mr. Douglas" read to the Royal Society on April 20, 1837, by Major Sabine.

Douglas began life as a gardener, and was sent to the United States as a collector first in 1824. After his return home, to make himself fit to render service to geographical and physical science, he began to study the principles of science and the methods of observations, and at one time worked at these subjects for eighteen hours a day. The observations he left in manuscript included among other things observations of the magnetic dip and intensity at various stations in North America and the Sandwich Islands.

Comparative Anatomy of the Brain

AT a meeting of the Royal Institution on April 21, 1837, Mr. Solly, of St. Thomas's Hospital, gave a lecture on the comparative anatomy of the nervous system and especially of the brain, and illustrated his views by reference to a number of well-executed drawings. Avoiding all minute details, he confined himself to the leading parts of his subject, of which he conveyed a very clear idea to his audience. He commenced with some remarks on neurine and its two kinds—the pulpy and the fibrous—whose offices he explained, and then proceeded to trace the nervous system, from the state in which it exists in the lowest kingdom of Nature in which its existence has been demonstrated, up to that in which it is found in man. In doing so he explained the most interesting points in the nervous system throughout the various divisions of the animal kingdom, and how the different senses are more or less developed according to the wants of each individual, as for instance, the sense of sight in birds. He also demonstrated most clearly that the simplest forms in which it has been possible to detect the nervous system are accurate types of its more complicated forms, and ended by briefly explaining the anatomy of the human brain. (*London Medical Gazette*, April 29, 1837.)

Conditions in Germany

THE following extract is taken from an editorial article in the issue of the *British Annals of Medicine* for April 21, 1837:

"Germany at present is in a very anomalous position. Her people are the best scholars in Europe, but they are without political freedom; they know nothing practically of representative self-government. The descendants of Arminius remain passively obedient to the princes under whose feet they happen to be born; and if in the different states the burthen bears unequally, this depends in no way on the will of the people, but on the accidental temper of the government. Government—paternal government—is carried to a revolting extent. Absolute ministers dictate to the people—a full-grown adult people—what they shall read. Only a certain number of foreign newspapers can enter Prussia, the press is submitted to censorship; an Austrian student could under no pretext obtain permission to visit France or England. Schönlein, Oken, Arnold—names which pronounced before a German student make his countenance light up with recollections of glowing thoughts and revelations of Nature—the most illustrious men have been driven, for liberal opinions, from their natural spheres—from the unnatural country, of which they were the glory, and are the shame".

University Events

Cambridge.—At Trinity College, the electors to the Wyse studentship in social anthropology have awarded a studentship of £300 for three years to Gregory Bateson, of St. John's College.

It is announced by the Philosophical Society that the adjudicators for the Hopkins Prize for the period 1930–33 have awarded the prize to Prof. P. M. S. Blackett, for researches on cosmic radiation.

St. Andrews.—At the graduation ceremonial to be held on June 30, the honorary degree of LL.D. is to be conferred on the following, among others: Dr. W. O. Kermack, Royal College of Physicians, Edinburgh; Dr. Angus MacGillivray, ophthalmic surgeon, Dundee; and Sir Arthur Rose, chairman of the Carnegie Trust for the Universities of Scotland.

Societies and Academies

Academy of Sciences, March 8 (*C.R.*, 204, 733–828).

Marcel Godchot and Mlle. Germaine Cauquil: The molecular transpositions obtained in the dehydration of 4-methylcyclohexylisopropylpinacone.

N. Gunther: Nuclei of the Fourier type.

Lucien Malavard and Joseph Pérès: The corrections for the walls in the case of a tunnel of elliptical section.

Albert Métral and François Raymond: A method of measuring the resistance exercised by the air on a railway train.

Jean Dufay: Nitrogen lines in the spectra of comets.

Jean Roubaud-Valette: The equations of the photon.

René Dugas: Quantum mechanics and the last multiplier according to Jacobi.

Ernest Baumgardt: The ultra-sound yield of piezo-electric quartz.

Nicolas Kurti, Paul Lainé and Franz Simon: Experiments on the thermodynamic scale of temperature below 1° K. Results of experiments by the method of adiabatic demagnetization using the large Bellevue magnet.

Douchan Avsec and Michel Luntz: Some new forms of electro-convective vortices.

M. Haïssinsky and Mme. H. Emmanuel-Zavizziano: The preparation of thin layers of titanium by the electrolytic method. Details of a method of preparing thin films of metallic titanium on a lead cathode, of a thickness about 0·1–0·2 mgm./cm.^{2}.

Pierre Mesnage: The molecular emission spectra of some metallic salts. Description of results obtained with manganese chloride, ferrous bromide and ferrous iodide.

Mlle. Hoàng thi nga: The photo-voltaic effects of the naphthalene diamines.

Marcel Chatelet: The partial precipitation of cobalt by ammonia in excess and the formation of cobaltammine ions.

J. Bénard and Georges Chaudron: The preparation of ferrites by the substitution of ferrous ions in magnetite.

René Delaplace: A method of analysis of saturated and unsaturated gaseous hydrocarbons under very low pressures. Application of the method of fractional distillation of the liquid gases under low pressures, with subsequent separation of the saturated and unsaturated gases by chemical means.

Jens Boe and Mlle. Madeleine Gex: Modifications of the spectra of aqueous solutions of phenylpyruvic acid as a function of the pH and of the time.

Albert Portevin and Pierre Chevenard: The cooling transformations of steels.

Marcel Prettre: The heterogeneous combustion of mixtures of carbon monoxide and oxygen on a vitreous surface.

Jean Baron and Paul Laffitte: The influence of nitrogen on the inflammation of diethylether. The results obtained for the variations of the temperature of inflammation of mixtures of ether, oxygen and nitrogen produced by varying the proportion of nitrogen present are in agreement with the theory of chain reactions.

Christian Aall: The influence of the impurities silica, alumina and magnesia on the melting point of calcium carbide. The experimental results are given graphically: the curves showing the lowering of the melting point have not the same form.

Mlle. Denise Hibert and Clément Duval: Cobaltic chloride. Of various methods available, the best consists in treating a suspension of cobaltic oxide in ether with dry gaseous hydrochloric acid, afterwards removing the ether and excess of acid with a current of dry air.

René Sutra: The formation of acetone derivatives of the mercaptals.

Mlle. Simonne Caillère: A special mode of alteration of anorthite and a calcium variety of thomsonite.

Marcel Gigout: The Palæozoic series of Adrar n'Dgout (Marrakech Atlas).

Edmond Saurin: The Trias of the Phu-Tinh-Gia sheet (North Annam).

Léonce Joleaud: The very recent morphological evolution of a group of archaic Ungulata, the Damans.

Frédéric Marie Bergounioux: The faunal relations between the fossil Chelonians of Spain and France.

Pierre Dangeard: The zones of marine Algæ of western Morocco.

Paul De Graeve: The evolution of puric nitrogen during germination.

Henri Gaussen: Young forms and future evolution.

Mlle. Fernande Flous: The transmission o characters in the hybrids of firs.

Constantin Dawydoff: A new metanemertean belonging to a purely marine group, from the Grand Lac of Cambodia.

Léon Binet and M. V. Strumza: Variations o the resistance to anoxhæmia according to the degre of narcosis.

Léon Képinov: Synergy of adrenalin and of th pituitary hormone. The mechanism of the glycogenolytic action of adrenalin.

André Paillot: The polyembryonic developmen of *Amicroplus collaris*, a parasite of the larvæ o *Euxoa segetum*.

Mme. Véra Dantchakoff: The effects of sexua determinism in a feminized male.

André Dognon, Wladislas Kopaczewski an Stanislas Marozewski: The absorption of ultraviolet rays by the serum and anaphylaxy.

Mme. Raymonde Duval and Jean Marie L Goff: The detection of small quantities of cobal in human urine. The cobalt is concentrated b electrolysis and detected by the α-nitroso-β-naphth reagent.

Nicolas Bezssonoff and Mlle. Mélanie Woloszyn: The duality of the oxidized forms and the polarization of vitamin C shown by two reversible reactions with phosphomolybdic acid.

Léopold Negre and Jean Bretey: The anti-tuberculous immunization of the ape by injection of tubercle bacilli from smooth colonies.

Fernand Arloing, Albert Morel and André Josserand: New researches on the action towards cancers of the soluble organo-metallic complex compounds of ascorbic and dehydrascorbic acids, where the iron is replaced by copper or titanium.

Jean Nageotte: Remarks on the surgical repair of losses of traumatic substances of the peripheral nerves.

Amsterdam

Royal Academy (*Proc.*, 40, No. 2, 1937).

F. K. T. van Iterson: Separation of substances by flotation. Mathematical treatment which shows that the greater the angle of contact the better the flotability of a substance.

J. A. Schouten: The differential geometry of groups of contact transformations (1). Doubly homogeneous treatment of contact transformations.

F. M. Jaeger: The relative and absolute spatial configurations of isomorphous optically active complex salts (2). Comparison of the tri-diamino salts of cobalt, rhodium and chromium.

F. M. Jaeger and L. Bijkerk: Investigations on the complex salts of the racemic and optically active cyclohexanediamines with trivalent cobalt and rhodium (2). The complex tricyclohexanediamine rhodium salts.

A. H. Blaauw and Miss H. G. Kronenberg: The epoque of the flower formation of the hyacinth and Darwin tulip in Holland and in southern France.

C. S. Meijer: Products of Whittaker functions.

J. Popken: An arithmetic property of certain integral functions.

J. A. Barrau: Self-projective point-casts in space.

A. L. T. Moesveld: Fundamentally wrong methods for establishing the non-existence of polymorphy.

J. H. C. Merckel: Relations between the melting points, boiling points and critical magnitudes and the number of carbon atoms in homologous series.

C. H. Andreas: Plant growth hormone and growth of the aerial roots of *Vitis gongyloides*.

F. Florschütz: Palæobotanical investigation in connexion with a supposed human settlement on the plateau of the Belgian peat moor (Houtes Fagnes).

H. D. M. Burck: Fauna of the Bartonian in Eastern Holland.

G. H. Voorwijk: Foraminifera from the upper Cretaceous of Havana, Cuba.

A. E. Walker: Experimental anatomical studies of the topical localization within the thalamus of the chimpanzee.

W. J. Roberts: Detection of gold in the brain and in the fœtuses of animals injected with sanocrysin.

F. Krüger: "Cellophane" as a substitute for kymograph paper.

A. de Buck: Some observations on the salivary and stomach secretion of *Anopheles* and other mosquitoes.

C. Visser: A certain class of conformal mappings.

Cracow

Polish Academy of Science and Letters,
January 11.

St. Loria and J. Klinger: The diffraction of electrons of average velocity.

Th. Banachiewicz: The calculation of determinants with the aid of Cracovians.

L. Chrobak and J. Chojnacki: The striped spots of Laue radiograms. The lines on the spots of the Laue photograms are due to the characteristic spectrum emitted by the anticathode.

K. Dziewonski, W. Gumulka and J. Moszew: New studies on compounds of the type of 2-aryl-4-amino or 4-hydroxyquinolines.

J. Lilpop: New plants from the Permo-Carboniferous in Poland.

Mme. J. Janiszewska: The third and fourth stage of the development of the larvæ of *Contracæcum aduncum* of the intestine of the flounder.

L. W. Wisniewski: The evolutive cycle and biology of *Parafasciolopsis fasciolæmorpha*.

M. Gatty-Kostyal, Mme. M. Paszkowska and Z. Zakrzewski: The influence of certain plant substances on the growth of grafted tumours. The aqueous extract of the tissues of a representative of the family Polyporaceæ, of species not yet exactly defined, has an intense inhibitive action of grafts of sarcoma on mice and rats.

H. Grossfeld: Metabolism and amœboid movement. The conditions producing visible amœboid movements in the Metazoa.

Moscow

Academy of Sciences, *C.R.*, 4, No. 9, 1936.

M. Krein: Differential oscillating operators.

P. Kalantarov: Selection of a system of units for measuring electromagnetic and mechanical values.

M. Kondakova and M. Kacnelson: 1-Ethyl-2-methyl-valeric acid.

M. Kacnelson and B. Dubinin: Researches in the series of normal acids with long chain closed by a cyclohexyl or a cyclopentyl (1). Cyclohexylvaleric acid and its derivatives.

M. Kacnelson and M. Kabačnik: Some derivatives of lupinine.

M. Kacnelson and J. L. Goldfarb: Synthesis of the furanic isomer of cocaine (methyl ester of 2-furoyleggonine).

M. P. Gerčuk and M. Kacnelson: Preparation of anhydrides of naphthenic acids.

G. Čelincev and E. Osetrova: Amide condensations. Preparation of benzoylacetone by condensation of N_1N-diphenylacetamide with acetophenone.

Ch. S. Koštojanc and T. I. Bekbulatov: Comparative study of the importance of respiratory rhythm for the condition of the central nervous system.

A. A. Isakova: The problem of the nature of the action of bacteriorhizal micro-organisms on plants. The action of the micro-organisms is of the hormonal type.

T. I. Privolnev: Respiratory rhythm during the segmentation of eggs of *Lampetra fluviatilis*.

G. A. Schmidt: (1) Development of the external gills from the ectoderm in Anura and from the entoderm in *Triton*. (2) Differences in the induction abilities of the organizing centre in Urodela and Anura.

Forthcoming Events

Monday, April 19

Royal Geographical Society, at 8.30.—Captain A. Dunlop: "The Dadessa Valley".

Tuesday, April 20

Institution of Civil Engineers, at 6.—Prof. S. M. Dixon, G. Fitzgibbon and M. A. Hogan: "The Flow of the River Severn, 1921–1936".

Thursday, April 22

Institution of Electrical Engineers, at 6.—Prof. J. Chadwick, F.R.S.: "The Elementary Particles of Matter" (Kelvin Lecture).

Friday, April 23

Royal Institution, at 9.—Prof. H. Mark: "The Synthesis of Large Molecules".

International Association for Testing Materials, April 19–24.—Second International Congress to be held in London.

Sir William Bragg: President.

Faraday Society, April 22–24.—General discussion on "The Properties and Functions of Membranes, Natural and Artificial" to be held in University College, Gower Street, London, W.C.1.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Lecturer in Chemistry in the Woolwich Polytechnic, London, S.E.18—The Secretary (April 20).

Assistants (grade II) at the Royal Aircraft Establishment, South Farnborough, Hants.—The Chief Superintendent (April 28) (quote Ref. 342/B).

Assistant Investigator (roof control and haulage) for the Safety in Mines Research Board—The Under-Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S.W.1 (April 23).

Lecturer in Mathematics and Elementary Physics in the Polytechnic, Regent Street, London, W.1—The Director of Education (April 26).

Lecturer in Biology in the Polytechnic, Regent Street, London, W.1—The Director of Education (April 26).

Research Chemist for the Bone Research and Development Association, Ltd.—Prof. W. A. Bone (April 26).

Assistant Investigator for the Safety in Mines Research Board—The Under-Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, London, S.W.1 (April 27).

Scientific Officers and Assistants (grades I, II and III) in the Chemical Defence Research Department, 14 Grosvenor Gardens, S.W.1—The Chief Superintendent (April 28).

Assistant (grade II, aeronautical materials) at the Royal Airship Works, Cardington, Bedford—The Superintendent (April 30) (quote Ref. B. 352).

Junior Scientific Officer in the Headquarters Office of the Department of Scientific Research, 16 Queen Street, S.W.1—The Establishment Officer (April 30) (quote J. 37/9).

Three Technical Officers (electrical engineering), One Assistant (grade II, physics or electrical engineering), and Two Assistants (grade III, physics or electrical engineering), in the Signals Experimental Establishment, Woolwich Common, S.E.18 (April 30).

Professor of Organic Chemistry in the Egyptian University, Abbassia, Cairo—The Dean of the Faculty of Science (April 30).

Assistant Veterinary Officer for the Essex County Council—The Clerk of the Council, County Hall, Chelmsford (May 1).

Lecturer in Mechanical Engineering in the Derby Technical College—The Clerk to the Governors (May 10).

Junior Engineer at the E.M.I. Laboratories—Electric and Musical Industries, Ltd., Employment Department, Hayes, Middlesex.

Temporary Assistant Engineers, Engineering Assistants, and Junior Engineering Assistants for trunk road survey of the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1.

Social Responsibilities of Science

ONE of the most significant features of representative scientific gatherings in recent years, even of such widely differing types as the British Association, the World Power Conference, the Society of Chemical Industry, or the Association of Scientific Workers, as in the reports of Carnegie Institution of Washington or the Carnegie Endowment for International Peace, is the concern which has been expressed at the social consequences of the application of scientific discoveries. The necessity for concrete action in this field has been emphasized in recent months in different ways by the attention being given to the problems of the Special Areas, the rearmament programme and the growing *malaise* in Europe. We are witnessing a race between scientific progress and social instability.

It is accordingly appropriate and welcome that the International Council of Scientific Unions, meeting for the first time in London, should have before it a proposal submitted by the Royal Academy of Sciences at Amsterdam for the appointment of a committee to endeavour to co-ordinate views advanced in recent years regarding the social responsibilities of science and scientific workers (see p. 697).

At present, however, it is difficult for any scientific worker to get a sufficiently clear and ample picture of the problems confronting us and their implications. The proposal, therefore, aims at providing a means of collecting the various opinions which have been brought forward in this sphere and presenting them in a form which may help individual scientific workers and scientific organizations to obtain a better view of their work and of their position in relation to social problems. In support of the proposal a memorandum which has been forwarded to the General Secretary of the International Union bears the signatures of seventy-four scientific workers from different countries, although in inviting support of its proposal the Amsterdam Academy did not address itself to men of science in Germany, in Italy or in the Union of Soviet Socialist Republics, on the ground that in these countries at present scientific workers are bound much more closely to their respective Governments than is the case elsewhere. Nor has support been sought from scientific workers who have emigrated from these countries; in the first instance, an endeavour has merely been made to ascertain the attitude to the proposal of men of science in countries where there is more freedom to express individual opinions.

That such a discrimination should be necessary in the twentieth century is a striking reminder that science has a spiritual message as well as its material aspect, and that it demands a supreme loyalty to truth which must over-ride all other claims if error and delusion are not to result. The search for truth is not fulfilled by giving bare facts, numbers or abstract theories only; there must be also some sense of values and of perspective.

The cherishing of such ideals is a primary function of professional associations whether on a national or an international plane, but to turn to such a programme of research as that set forth in Sir Josiah Stamp's "The Science of Social Adjustment" is to realize the imperative need for scientific organizations to draw together if the beginnings of an attack on these problems is to be contemplated. Equally it is clear that a bridge must be built from the general but indefinite consciousness of social responsibilities to a definite practical campaign in this field. Clear thinking about the social implications of scientific work, of the uses that are being and could be made of science, of the abuse of scientific knowledge, and of the fuller use which could be made of it for promoting general social welfare, is the prelude to effective action.

For such thinking, data must be assembled as basis for judgment, and it will still remain to determine the means of making such judgments more effective in the struggle of opinions by which the world is ruled. In the memorandum which accompanies the proposal of the Amsterdam Academy, the possibility is reviewed of interesting existing organizations in this work, and reference is made in particular to the admirable work of co-operation which has already been fostered by the League of Nations in the field of international health and intellectual co-operation. It is suggested that fuller use might be made of the scientific point of view in the work which the League undertakes in adjusting political and social conditions.

The largest general scientific organization, however, is the International Council of Scientific Unions, and it was at first suggested by the Amsterdam Academy that the International Council might regard it as part of its task to consider opinions brought forward from various sides concerning the attitude which should be taken by scientific workers in relation to the dangers at present menacing the future of our civilization. On this basis consideration of the social responsibilities of science could be introduced into various aspects of the Council's work, particularly that carried out on behalf of the League of Nations.

A mere statement of this kind, however, is too wide to lead to the initiation of any concrete piece of work, and the resolution finally submitted to the Council accordingly proposes the appointment of a special committee in the following terms :

"The International Council of Scientific Unions, already at a former occasion having expressed its faith in the possibility and the necessity of peace between the world's peoples, and being convinced that the 'brotherhood of scientists' can be an important factor towards the establishment of a desire for mutual understanding and helpfulness, considers it to be a part of its task to give attention to the opinions brought forward from various sides concerning the attitude which should be taken by scientists in relation to the dangers which at present menace the future of our civilisation.

"The International Council therefore decides to appoint a Committee, which should attempt to arrive at a co-ordination of what has been proposed in respect to the social responsibilities of science and of scientific workers."

It is intended that this work should be carried out in a way which will relate the points of view expressed so that the result may be a guide for those interested in these matters. Moreover, such a committee would no doubt attempt to formulate some general conclusions which might indicate where scientific thought or the personal influence of scientific workers could assist in analysing and attacking social problems, and which might also help individual scientific workers to choose their own point of view in co-operating to safeguard our cultural advance. At the same time, the committee should serve as a centre of contact for organizations and persons interested in this type of cultural work, and assist in creating between these organizations and persons a feeling of mutual sympathy and of solidarity.

It can scarcely be challenged that such a committee could render almost invaluable service, both in the education of public opinion as to the contribution of science in social matters, and in the stimulation of scientific investigation, as well as of effective co-operation between professional organizations, to provide not merely a definite professional code but also a permanent anchorage or shelter from which members of the profession of science would be free to render their special service and exert their full influence undeterred by political or any other type of prejudice. It is indeed only from some such vantage ground that scientific workers can assist humanity to link up science with ethical values, and derive the courage and the authority needed at times to denounce the abuse of scientific effort or results, and to point out positive means of promoting the well-being and co-operation of mankind.

It is unnecessary at this stage to go further into the programme of activity for the committee sketched by the memorandum. The opportunities which confront us in such matters as nutrition, the problems of the Special Areas and the location of industry, the prevention of accidents and industrial disease, are only a few examples of questions to which reference has recently been made in these columns, in respect of which scientific workers might make an important or decisive contribution. Surveys of these fields, of the possibilities of assuring a certain standard of life through a full use of scientific and technical means of production and distribution of food and general commodities, and of the alleviation of poverty and misery; the prostitution of scientific knowledge for ignoble uses and in particular for purposes of war, and the development of a code of ethics and the question of a right attitude to preparations for war; the study of racial relations and feelings are all touched upon in some detail by the memorandum, and indicate the vast field in which fruitful work could be done. No scientific worker who realizes the benefits which science is able to give to society, or who desires to exert his full influence in social affairs, whether as a citizen or in his special capacity as a scientific worker, can be indifferent to the proposal or programme outlined by the Amsterdam Academy.

What matters above all, even in the collection and co-ordination of the existing material, is the spirit in which the work is carried out. Only as that is dominated by the highest ideals and finest loyalty to that spirit of service inherent in science itself can we expect to arouse the devotion and to create the vision which will enable the many difficulties in the way of effective action to be overcome. Even if the committee starts with a comparatively restricted field, that need not hinder it from rekindling the finest ties of professional loyalties and a vision of the possibilities and benefits which the scientific spirit linked with a sense of human values might bring to mankind. Once that is kindled, the human spirit will not long delay to break the shackles with which craven and retrograde political creeds and nationalist systems have sought to restrain its advance into an age of freedom and plenty, where man's mind and spirit, released from the cramping influence of poverty, disease and war, may achieve a stature and creative fertility hitherto unknown.

Personalities in Natural History

Green Laurels:
the Lives and Achievements of the Great Naturalists. By Donald Culross Peattie. Pp. 38+429 plates. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1937). 12*s*. 6*d*. net.

THE author enjoyed his book, coining happy and striking phrases and suggesting interpretations of great characters. Goethe is "the father of the German romantic movement in poetry and science" and the Nordic interprets himself as "everything upstanding, gifted, pure, great and superior". Darwin is a "kindly English gentleman known by his good works", whose twenty years' record of silence is unsurpassed. Wallace was the greatest of professional collectors, because "he thought as he collected", but he was an "humanitarian before he was a scientist . . . a virtue only in a Romantic"; "disgraceful wrangles . . . never between these two". The old ideas were ancestors of theirs; "they built upon the sunken piers of obsolete wisdom". It is to sketch these "piers of nature's unfolding in the mind of man" that pleasures the author, not a history of biology and an orderly sequence of discovered facts. Plato, Aristotle, Theophrastus, Dioscorides, Galen and Pliny held the field until sixteenth-century Gesner published his "Historia Animalium" with Dürer's illustrations. In this man is seen the universality of science, for, from his Swiss home, he corresponded among others with Belon, whose picture of the bones of man and bird founded comparative anatomy, Rondelet (fish-lover), Aldrovandi (traveller), and Turner.

We are rather pleased to escape Vesalius and Harvey and to think of Borelli and Redi as unruly members of the first "Accademia del Cimento", unknown adventurers "on the rim of a volcano". There is sympathy for, and understanding of, Malpighi, Swammerdam and Leeuwenhoek in the first great days of microscopy. Réaumur is a brilliant of purest water, meteorologist, metallurgist, biologist, creator of entomology. In contrast, Buffon, protégé of the Pompadour, recreator of the Jardin des Plantes, prolific writer, courtier, in his jealousy and pride true forerunner of Cuvier, his fame crushed in our minds by his championship of spontaneous generation against the experiments of Spallanzani. Here were gleams of evolution, but the next volume affirms a belief in the scriptural creation "both as to order of time and matter of fact". Linnaeus appeals, a country "sport", great collector and systematizer without whose work further progress had become impossible. He had forerunners, of course, especially Ray, and they, too, had made approach to the idea of sexuality in plants and its analogue in animals.

It was a glorious age, the collecting of Nature from every clime and isle—and in the story there is no elimination of that personality, which never gives enduring fame, but on which is founded human love. Thus is approached that great "chevalier" Lamarck, who founded the "concept that evolution is possible, is real, is more characteristic of life than motion or breathing". There was no success here, a penniless old age, no helping hand from Cuvier, the man and all his work ungratefully contemned by him, his bones consigned to the pauper's tomb. Happy it is that Owen was no Cuvier in Darwin's days, and that Lyell preceded and Huxley lived. Personal humility, genius and confidence are, indeed, three factors in science.

Later, a few chapters to tell us about the early collector-naturalists of North America. We all know of sour Wilson with his pictures of museum-stuffed birds, and flighty Audubon with his nature brush. Few know C. S. Rafinesque, of the University of Transylvania, literally built in the backwoods, its golden age synchronous with his professorship, 1819–26. Here was a picturesque and eccentric genius, dabbler in every field of biology with incursions into Indian archæology and language, member of a score of scientific societies, but yet a failure, since never a single idea or suggested thought was carried to fruition. Returning from an excursion, Rafinesque found his museum swept bare and was denied his classroom, the villain of the piece, President Holly himself, driven out next year by his fundamentalist students. Here again a death in abject poverty, the body almost cased in the nine hundred books and pamphlets it had written.

Then there were the Bartrams, father and son and families, the father fresh from the plough to become the correspondent of Linnæus and the fashionable world of England, all collectors then. The gorgeous *Franklinia* was theirs, those living now descended from a single tree of Georgia never since found wild. Michaux, a French farmer, was sent over in 1785 to collect trees and plants for the forest of Rambouillet, but, although he shipped a vast abundance, Nature in Europe formed too close a "society" for them; he is better known for his later contributions from the East. Jefferson, third President of the United States, was a naturalist, but surely the strangest enterprise and settlement must have been that of New Harmony, the communistic State founded in 1825 by thirty-five ladies and gentlemen from the cultivated purlieus of Philadelphia. Kindly Robert Owen was the founder, an immigrant from Lanark, not appreciated there—the experiment a failure, but New Harmony a place of pilgrimage for fifty years. Here the great "American Conchology" of Say took shape, its author's name-seal to be ever associated with a large share of the animals of North America, his associate Lesueur responsible for its exquisite plates. A most pleasant book.

J. S. G.

Secret Languages of Ireland

The Secret Languages of Ireland: with Special Reference to the Origin and Nature of the Shelta Language, partly based upon Collections and Manuscripts of the late Dr. John Sampson. By Prof. R. A. Stewart Macalister. Pp. x+284 (Cambridge: At the University Press, 1937.) 16*s*. net.

SHELTA, or more correctly Sheldrū, a secret language found among a certain class of tramps in England and current among Irish tinkers, was discovered in 1876 by Charles Godfrey Leland, that enthusiastic, if somewhat erratic, student of everything appertaining to the customs and beliefs of peasantry, gypsies and vagabonds generally all the world over. The results of his investigations of Shelta were ultimately passed to the late John Sampson, the great authority on gypsy languages, and through him brought to the notice of Kuno Meyer, the Celtic scholar, by whom the language was at once hailed as a survival of the old Celtic used by the Druids. Unnoted until the time of Leland, it has since been investigated by a number of Celtic and Romani scholars, with results which would now seem to have failed to justify early enthusiasms.

The book on the language, which was to be produced by Leland, Meyer and Sampson, was never completed; and on the death of the last named, the material which had been collected for it was passed to Prof. R. A. Stewart Macalister. Very wisely, while using this material, he has written his own book, enlarging the scope of the inquiry to include as a whole the intriguing problem of the occurrence of a number of 'secret' languages in early and medieval Ireland, and the evidence for their survival until recent times. It is a problem which not only has provided material of interest to the phonetician and the philologist, but also as a development which can be traced back to early historic times in Ireland, of no little significance for the student of the growth of social order and religious belief in that country.

Prof. Macalister discusses the whole problem with thoroughness. Beginning with the use of oghams as a method of alphabetic writing, which he believes, probably with justice, to be a deliberate archaism, intended to preserve, if not to create, an esoteric atmosphere, he goes on to discuss in considerable detail the various methods of cryptographic record which were adopted by the Irish scribe. This he follows with a discerning sketch of the social and religious conditions, which would have tended to preserve the Druidic custom of using at need a language understood only by the initiated ; and from this traces the rise of those bastard dialects, Hisperic Latin and Hisperic Irish, as well as the jargon known as Bog Latin. In regard to Hisperic Latin, he might, perhaps, have pointed out that this development is not peculiar to Ireland, and have found a parallel in the language of the macaronic verse of "The Battle of the Frogs and Mice", the Italian burlesque in imitation of the Aeneid. The vocabularies and analyses which Prof. Macalister gives of these secret languages, as well as of the modern Shelta and "Vernacular of the Masons" are of extreme interest.

The author completes his picture of the conditions which favoured the production and perpetuation of these languages by a brief sketch of the vagrants of Ireland. The accession of declassed clerics to these vagrant bands will explain, he holds, some anomalous evidence of learning which appears in the secret languages. As regards the central theme of inquiry, his conclusion is that Shelta does not represent an ancient language, though there are, not unnaturally, archaic elements in it, and that while its vocabulary is Irish, its syntactical construction is essentially English.

Bibliography of the Exact Sciences

Sotheran's Bibliotheca Chemico-Mathematica: Catalogue of Works in many Tongues on Exact and Applied Science. Second Supplement. Vol. 1. Pp. xi+840. Vol. 2. Pp. iii+841–1396. (London: Henry Sotheran, Ltd., 1937.) 21*s.* net.

THE second supplement to Sotheran's "Bibliotheca Chemico-Mathematica" lists no less than 22,895 items, thus exceeding in length not only the first supplement, but also the original two volumes. The arrangement of the contents is similar to that adopted in the first supplement. The individual items are arranged under a series of subject headings, instead of under a general alphabet, as is the case in the earlier volumes. This supplement has in fact been produced by binding together thirteen different special subject catalogues that have appeared separately during the last fourteen years. For this reason, presumably, the compiler has not thought it necessary to prepare a detailed subject index, a feature that rendered the original work especially valuable. However, the new arrangement may well prove more convenient to many users. The main subject headings in this great catalogue are as follows: aeronautics, astronomy and astrology, chemistry, chemical technology, engineering, geology and meteorology, horology and dialling, mathematics, microscopy, mineralogy, mining and metallurgy, navigation and physics. Some of these subjects are further subdivided, and there are also sections dealing with scientific works of general interest, collected works and sets of scientific periodicals. In the new supplement, nautical, aeronautical, mining and engineering works are more fully represented than in preceding volumes of the "Bibliotheca".

Those familiar with the catalogues of scientific books issued from time to time by the old-established firm of Henry Sotheran, Ltd., will realize the value of this supplement. To others it may be pointed out that, as catalogues of second-hand books, they are among the select few that have permanent interest and value. Comparable catalogues are issued by only a very few antiquarian booksellers, either in Great Britain or elsewhere. Those issued by Henry Sotheran, Ltd., excel, in the first place, in sheer numbers of books listed, these including both modern and standard texts and old, historically interesting publications of the sixteenth, seventeenth and eighteenth centuries. Secondly, the catalogues are not restricted to the more important (and therefore more valuable) works, but include also the lesser known writings of well-known men of science, and many books by obscure and almost unknown authors. Moreover—and herein lies the especial value of these catalogues—a very large proportion of the entries are annotated with bibliographical, biographical and historical notes. These notes, sometimes of considerable length, are drawn from many different authorities, and are remarkable for their accuracy.

No comprehensive bibliography of the exact sciences exists, and indeed the preparation of such a work would be a monumental task. Very few of the separate sciences have, in fact, formed the subject of special bibliographies. Such as exist are invariably incomplete, and are often either inaccurate, or lacking in bibliographical detail. It may fairly be claimed that this new supplement, together with the three preceding volumes of Sotheran's "Bibliotheca Chemico-Mathematica", comprising in all 47,480 entries, form the nucleus of a complete bibliography of the exact sciences, and an essential addendum to the few special bibliographies already existing. It is therefore a work of very definite value to librarians, bibliographers and historians of science.

The "Bibliotheca", being compiled from successive priced catalogues of an antiquarian bookseller, suffers from the unavoidable defect that a proportion of the entries are repeated. This repetition throws an interesting sidelight on the value of old scientific books. A comparison of the prices asked in earlier volumes of the "Bibliotheca" with those asked for the same work in Sotheran's latest catalogues indicates unmistakably that a marked increase in the value of at least the more important early scientific books has taken place during the last fifteen to twenty years An outstanding example is afforded by Newton's "Principia", the first edition of which might have been purchased in 1919 for £30; in 1934, £120 was asked for it. Other examples could be quoted in confirmation of this trend in prices, which must indicate not only an increased demand for this type of book, but also a growing scarcity. Librarians throughout the world are filling gaps in their collections, and it seems probable that before many years pass it will be extremely difficult, if not impossible, to obtain copies of the outstanding early works of science at any price.

The compilation of the "Bibliotheca Chemico-Mathematica" is entirely the work of Mr. H. Zeitlinger, a member of the staff of Henry Sotheran, Ltd. Mr. Zeitlinger is obviously equipped, not merely with a critical sense of the value of the books he catalogues, but also with an exceptionally wide knowledge of the bibliography and history of science, qualifications which render valuable the notes with which he enriches his catalogues. Both he and the publishers are to be congratulated on the production of a work of such interest and lasting worth.

Marine Zoo-geography

Tiergeographie des Meeres
Von Prof. Sven Ekman. Pp. xii+542. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1935.) 32 gold marks.

THE collection of specimens of marine animals by individual workers and on fully organized expeditions has been carried on for many years, and still continues. To the systematic zoologist, much of the interest in these collections lies in the discovery of new or rare species which may throw light on evolutionary trends and classification. But the gradual accumulation of publications giving the faunistic results of collections, and often comprising lists of already known species, serves another purpose. Each record marks a pin prick on the globe to add to our picture of the geographical distribution of that species. It is only after many years of such recording of already described and well-known species have passed that this second purpose can reach fruition in an outline of marine zoo-geography.

Already in 1896, Ortmann had produced his well-known "Tiergeographie der marinen Organismen", giving a preliminary outline of the different faunistic regions; but almost all the results of the collections of the great oceanographical expeditions have been published since that date, and we have now a wealth of data out of all proportion to that available in Ortmann's time. Many of these reports contain summaries of the known distribution of separate groups or families, but there has been no comprehensive survey of all these results as a whole. Prof. Sven Ekman's book is therefore welcome and timely. He gives an outline of all the marine faunistic regions as they exist to-day and their relationships one with the other. In order that the relations between the different faunas might be disclosed, their composition has had to be studied in the light of geological evidence, and this is one of the main aspects of the book, which is not only an outline of present-day marine zoo-geography but also a history of its past and of the causes that have produced its characters to-day. All types of faunas are dealt with, from the littoral to the abyssal, including the pelagic and planktonic animals, of all the oceans and seas as well as of the Caspian Sea and the Sea of Azov.

As might be expected, it is the tropical littoral fauna with its limited methods of dispersal that shows the least geographical uniformity at the present day. In the Cretaceous and early Tertiary, the tropical fauna of the Indo-Pacific and Atlantic regions had much in common, being united by the shallow Tertiary sea of Tethys. Climatic change in the Atlantic and the gradual emergence of land destroyed much of the tropical Atlantic fauna, and initiated the present era with its strong contrast between Atlantic and Indo-Pacific faunas. Results have shown that the term Indo - West Pacific must replace the older expression Indo-Pacific, since the faunas of east and west Pacific are radically different, the former having affinities rather with the Atlantic region The vast island-free area between Polynesia and America was presumably the barrier between the littoral faunas of east and west Pacific. Later climatic change in the North Atlantic with its warm conditions also impeded the evolution of an endemic boreal fauna, which is so much richer in the Pacific.

Such are the type of conclusions brought forward in this most interesting book. Although much of the theoretical picture has previously been constructed by workers in individual animal groups, the probable truth gains added strength by Ekman's work, which has shown how different groups of the animal kingdom follow the same trends. The book is well illustrated, and contains a valuable literature list of some twenty-six pages. This list has an additional attraction in that all titles of papers are given in full, and it thus forms a most useful guide to many of the most important reports on all the marine animal groups.

Prof. Ekman's book is more than a text-book, and is one of the most important additions to marine biological literature since Murray and Hjort's "Depths of the Ocean". Perhaps one of the most striking features brought out is how very great has been the advance in knowledge of species of marine animals within the last century. We cannot be far wrong in saying that in many groups the identification and description of the component species is nearing completion in certain regions. It behoves us now to pay increasing attention to the biology of the species themselves and their interrelationships one with another. It is only with such knowledge that we shall reach a correct understanding of the factors which bind the species to the different ecological associations in the zoo-geographical regions which Prof. Ekman has so ably outlined.

F. S. R.

Catalytic Reactions

Catalytic Reactions at High Pressures and Temperatures

By V. N. Ipatieff. Pp. xxii+786. (New York: The Macmillan Co., 1936.) 30*s*. net.

THIS is a chemical autobiography; it concerns the life researches of a great Russian chemist, now an exile and professionally active in the United States in the field of catalysis and its industrial application. The author seeks to have correct significance placed upon his investigations, which he claims has not always been done; he retaliates by making little reference to the work of others. As a result, the reader is presented with a mass of information often stimulating and suggestive, which however should be approached critically. It is most valuable to have a subject presented in this way instead of the judicial form necessary in the text-book; instead there is the zeal of the author convinced of the importance of his discoveries and the soundness of his hypotheses. Such are developed here for the reactions of dehydration, alkylation, polymerization and isomerization, in some instances for the first time.

The name of Ipatieff is in particular associated with his pioneer work on catalytic reactions at high pressures and temperatures, and his method is followed industrially in the preparation of such products as cyclohexane, tetralin and decalin. A summary of the main lines of his researches is given in an introduction. He was the first to observe in 1900 that a catalyst could influence the course of decomposition of an organic substance and force the decomposition to go in a certain direction only, and also to recognize that the material of the vessel might play the part of a catalyst. He showed how, according to the nature of the catalyst, alcohol could break down almost quantitatively in three different ways, to aldehydes, to ethylene, to butadiene. To-day such principles are universally recognized and made use of in diverse branches of the chemical industry.

The book is divided into thirteen chapters in which under appropriate headings the various sections of the subject are collected: these are sometimes rendered more useful by a series of numbered conclusions at the end. It can serve no useful purpose, even it it were possible, briefly to summarize some of Ipatieff's hypotheses and results, nor are all of them generally accepted.

The book will be read eagerly by workers in the field, particularly by those in industrial laboratories, and few will do so without some gain either in ideas or knowledge. The author's work has not been in vain; his contribution to progress is a substantial one.

The Human Foot:

its Evolution, Physiology and Functional Disorders. By Prof. D. J. Morton. Pp. xiii+244+14 plates. (New York: Columbia University Press; London: Oxford University Press, 1935.) 15*s*. net.

The author of this book, though he bears the name, is not responsible for the designation which we know as Morton's metatarsalgia. The most important statement in the book is that the disabilities of the foot start in the first instance from defects of the bones and ligaments. The evidence for this statement is assembled from diverse sources.

Approximately one third of the book is devoted to an account of the evolution of the foot. This is quite interestingly and well done, and is in accordance with the prevailing ideas at the moment. It is inevitable that its truth should be more general than particular. From gaps in our knowledge, detailed speculation as to the way individual muscles may have changed to meet new functional demands must remain speculative and have little value as proof. From his evolutionary studies, the author arrives at the conclusion that the foot has become a coherent elastic arched contrivance in which bone and ligament differ only in calcium impregnation, but otherwise are short or long trabeculæ answering to the stresses and strains imposed upon them. The muscles have but to balance the legs and the body upon the foot.

The analysis of the postural and locomotory activities of the foot but bear out this contention, and the disabilities of the foot are of course interpreted in the same way In the examination of nurses and students, the author estimated the power of the muscles in those who had static change of the foot and found this the same in those who had no such disabilities. The opposing view asserts that in the maintenance of the configuration of the foot the muscles stand in the first line of defence; the ligaments are resistances invoked against external forces only after the muscles have failed. The reflex postural activity of muscles maintains not only the equilibrium of the body but also the form of the foot. It is the penetration of this conception into the practice of orthopædics that has elevated its teaching and enhanced its results. The work of British medicine in bringing this about has been very considerable, and it has become widely adopted elsewhere. The problem at issue is one of clinical investigation and cannot be settled by appeals to a more or less speculative evolutionary background.

A National Encyclopædia of Educational Films and 16 mm. Apparatus available in Great Britain, 1936

Edited by William L. Lally. Pp. 479+7 plates. (London: The Central Information Bureau for Educational Films, Ltd., 1937.) 15*s*.

This is a new, enlarged, and again improved edition of a work first published under its present name in 1935 but really dating back to 1933. The improvement—and it is an immense improvement—consists in the inclusion first of a film title index giving reference to both 35-mm. sound and silent and 16-mm. sound and silent films, and secondly, of a new subject index to the main classification. The first meets a criticism which we made of the first edition that there was no possibility of direct reference to any specific film when the title was known, and the second enables us to find films that deal with any particular topic. The encyclopædia is now in fact usable without a great expenditure of energy and temper.

Although it is now possible to trace films, the process is not even yet quite so simple as it might be. If we wish to obtain a film on a particular subject, we first turn to the subject index and choose a name. Then we look up this name in the index to titles. Perhaps we were unlucky, but when we looked up 'Cacao–Trinidad' and 'Cocoa from Trinidad' we could find neither. If the name is given, we find whether it is 35-mm. sound or silent or 16-mm. sound or silent, and on what page further particulars are given. We turn to that page, identify the film and find the source of supply and its length. 'Identify' is the word to be used, for when we looked up "Hop Gardens of Kent" as given on the title index, we found "Hoplands" not on the page named but the next. Nor is this the sole example of transmutation of titles.

The lengths are still given in reels. This is not quite satisfactory; for it makes a great difference to the suitability of the film whether it runs for 7 or 15 minutes. But this, with some other matters, can be attended to in future editions. It is a great advance to have a catalogue that is usable.

Grundlagen, Methoden und Ziele der Hygiene:

eine Einfuhrung fur Mediziner und Naturwissenschaftler, Volkswirtschaftler und Techniker. Von Prof. Dr. Werner Kollath. Pp. xvii+508. (Leipzig: S. Hirzel, 1937.) 18 gold marks.

The preface declares that this book is intended as an introduction to hygiene for the student of medicine and also as a stimulus for the interested layman to introduce hygienic methods wherever this may be possible. The plan of the book is good in that the first part is devoted to the scientific foundations of hygiene, the association of physics and chemistry with biology and of biology with medicine. Subsequent parts deal with environmental hygiene, with nutrition, with medical statistics and public health organization, and the last part with bacteriology and serology.

The book, however, is too ambitious in trying to cover too much in five hundred pages. Balance is not maintained, the writing being either too discursive or too laconic. Twenty-three pages are devoted to atomic physics, ten pages to oxidation-reduction potentials, but immunology is accorded only nine and medical statistics only thirteen pages. Epidemiology receives only passing mention, and even the problems of milk-borne infections are dismissed by giving an incomplete list of the diseases which may be spread by milk. The bibliography makes mention of a number of text-books and gives references to fifty-six papers on a large variety of subjects by the author himself. The book is not likely to appeal to the English reader.

The International Council of Scientific Unions

THE International Council of Scientific Unions, formerly the International Research Council, will meet at the rooms of the Royal Society, for the first time in Great Britain, on April 26. The original statutes laid down that the triennial meetings of the Council should be held at Brussels, but these were altered in 1931 to empower the General Assembly to accept invitations from other countries

The present Council was established in 1919 after its predecessor, the International Association of Academies, had lapsed during the Great War after actively promoting international science for about sixteen years.

For some years before 1898, the Academies of Munich and Vienna, with the Royal Societies of Gottingen and Leipzig, had been in the habit of meeting annually at one or other of these places as an association to discuss matters of common interest, and in 1898 they were to meet at Göttingen. The Royal Society of Göttingen invited the Royal Society to send delegates to take part in the meeting and its discussions, and also intimated that the four institutions would be glad to learn the views of the Royal Society on the possibility and desirability of its joining them. The Council of the Royal Society accepted the invitation and instructed its delegates to say that the Society would be disposed to join the association provided that it were so extended as to assume a fully international character. The suggestion was accepted in principle, and the Royal Society was requested to take such steps as might be desirable to ascertain how far the formation of such an international association might commend itself to the leading scientific bodies of other countries. As a private institution, the Royal Society was very favourably situated for opening such negotiations.

In the following year the Académie des Sciences of Paris, the Academia dei Lincei of Rome, the Imperial Academy of Sciences at St. Petersburg, and the National Academy of Sciences at Washington, approved of the proposal and expressed their readiness to join such an international association. A preliminary conference was therefore held at Weisbaden in October 1899, at which a draft scheme for the organization was prepared providing for triennial meetings of the General Assembly, which would consist of delegates from each adhering Academy. The Assembly was to be formed of two sections, one for the natural sciences, and the other for literature and philosophy. The Council of the Association held its first meeting at Paris in 1900.

By the organization of the association an academy might be admitted either to the literary section alone, or to the scientific section alone, but not to both unless its constitution showed that the sphere of its labours included both literary and scientific subjects ; and as at that time there was no society in existence in England dealing with the subjects of the literary section in such a manner as to satisfy these conditions, the United Kingdom could only be represented in the scientific section by the Royal Society. The Council, therefore, consulted several distinguished men of letters, a number of whom afterwards submitted a memorandum in which it was suggested that the Royal Society might either enlarge its scope so as to include a section corresponding to the philosophical, historical and philological division of some foreign academies ; or that it might address a memorial to the Government pointing out the exceptional position in which Great Britain was placed as compared with other European countries through the absence of any academy representing departments of study other than mathematics and natural sciences, and advocating the formation of such an academy.

In 1900 the Council of the Royal Society appointed a committee of fellows of the Society to consider this memorandum and to report. The committee went into the whole matter very thoroughly and, after conferring with a number of representatives of historical and philological studies, presented a report, which was laid before a special meeting of the fellows, at which a very full and interesting discussion of it took place on May 9, 1901. The report came before the Council again at its meeting in July, and after full consideration it was resolved "that the Council while sympathising with the desire to secure corporate organisation for the exact literary studies considered in the Report, is of the opinion that it is undesirable that the Royal Society should itself initiate the establishment of a British Academy".

At the end of 1901 a number of those who had taken part in these discussions formed a new body, the British Academy for the Promotion of Historical, Philosophical and Philological Studies. This body drew up a petition to His Majesty in Council for the grant of a Royal Charter, and in 1902 the British Academy for the Promotion of Historical, Philosophical and Philological Studies was constituted, and incorporated by Royal Charters.

During the Great War, the periodical meetings of the International Association of Academies and of many other international organizations could not be held, though some of them were continued in neutral countries. In 1918, therefore, the Royal Society, the Academy of Sciences, Paris, and the National Academy of Sciences, Washington, discussed informally the question of the future organization of the scientific undertakings which had been carried on before the War by international co-operation; and ultimately the academies of all the allied countries were invited to send representatives to a conference which took place at the rooms of the Royal Society in October 1918. This was followed by a meeting at Paris at the end of November, when it was agreed to form an International Research Council and a number of affiliated International Unions to deal with matters of international scientific interest, which was done at Brussels in the next year.

Besides the ordinary routine of the triennial meeting, which is being held in London on April 26–May 4, the Council will have for consideration the report of the standing committee on the Study of Solar and Terrestrial Phenomena, and also that of the committee which was appointed three years ago to report on the relations which should exist between the Council and the Committee of Intellectual Co-operation of the League of Nations concerning matters of international science.

The Royal Academy of Amsterdam is proposing that the International Council should appoint a committee to study what co-ordination can be achieved in the opinions which have been put forward regarding the social responsibilities of science and of scientific workers towards the dangers at present menacing the future of civilization.

Public lectures will be given on April 28 and April 30 at the Royal Institution; the former by Sir William Bragg, on "Classical Experiments made at the Royal Institution", and the latter by Prof. E. V. Appleton, on "International Co-operation in Radio Research". The Government is giving an evening reception to the delegates at Lancaster House on April 29.

Arrangements have been made for the delegates to visit a large number of scientific institutions in and near London, where they will receive assistance from members of the scientific staffs in the objects of their visits.

The General Assembly will hold its closing meeting on Monday, May 3, and the delegates will attend the soirée of the Royal Society on Tuesday, May 4.

On Tuesday, April 27, there will be a reception of the delegates at the University of London, when the Chancellor of the University, the Earl of Athlone, will confer the honorary doctorate of science on Dr. N. E. Nörlund, the president of the International Council.

The Total Solar Eclipse of June 1937

THE total eclipse which starts on June 9 next and, crossing the date line, ends on June 8, will be the longest visible for many years, the maximum duration of totality being 7 minutes 4 seconds. It is most unfortunate that the belt of totality lies almost entirely over the ocean and that the maximum duration available from land is reduced to 4 minutes 8 seconds. This is from Enderbury Island in the Phoenix Group (lat. 3° 8·5′ S., long. 171° 10·0′ W.) which is described in the *Sailing Directions, Pacific Islands Pilot*, vol. 2, 1932, as "30 feet high, uninhabited and surrounded by a coral reef, which is steep to. There is no fresh water, no anchorage and landing is difficult". The island is about 2·5 miles long and 1 mile wide. Of the other islands in the Phoenix Group, which lie within the belt of totality —Gardner, McKean, Hall, Birnie, Canton and Phoenix, all uninhabited—the most suitable island for landing eclipse apparatus appears to be Canton Island (lat. 2° 28·9′ S., long. 171° 42·6′ W.). Here totality lasts 3 minutes 45 seconds The island is a coral atoll 10–12 feet high, with a spacious lagoon: there is anchorage, in 10 fathoms, unsafe with westerly winds, close to an entrance to the lagoon on the west side. Coco-nuts have been planted on the island, which is nine miles long by four miles wide. The islands are leased by the Colonial Office to Messrs. Burns Philp (South Seas) Co. Ltd., and come under the jurisdiction of H.E. the High Commissioner for the Western Pacific at Suva, Fiji.

The belt of totality east of the Phoenix group never strikes land until at sunset it reaches the coast of Peru. The U.S. Navy reported an island, Sarah Anne Island, which would have lain in the track of the shadow, but the island must have sunk below the ocean as it is no longer to be found. In Peru the maximum altitude of the sun is 8° and the maximum duration of totality 3 minutes 20 seconds. The Faculty of Science of the University of San Marcos has formed a committee to help visiting scientific expeditions in all matters of transport, meteorology, health conditions and camp installation. The Dean of the Faculty, Prof. Godofrich Garcia, is president of the Committee.

So far, three expeditions have been announced as going to observe this eclipse. With the aid of a sloop of the New Zealand Navy, Mr. C. B. Michie, of Kaitaia, N.Z., is taking a party consisting of Dr. W. C. Burns and Mr. F. Gawith—all three being members of the 1930 expedition to Niaufou' or Tin-can Island—and Mr. Thomsen and some other member of the staff of the Dominion Observatory. The 19-foot coronagraph used at the eclipses of 1926, 1929, 1930, 1932, and 1936, has been sent to Mr. Michie from Japan and will be taken by him to Canton Island. By kind permission of the Royal Irish Academy, the 8-inch Grubb cœlostat will be used to feed the coronagraph. Photographs of the corona will, it is hoped, be secured through various colour-filters. Other details of the programme are not available here.

Another party will be organized by the U.S. Navy, the National Geographic Society and the National Bureau of Standards, and will proceed to Canton or Enderbury Island. Prof. S. A. Mitchell, director of the Leander McCormick Observatory, will be the scientific leader of the expedition, while Captain J. F. Hellweg, Superintendent of the U.S. Naval Observatory, Washington, will be responsible for the naval side of the work. Dr. H. D. Curtis, director of the Ann Arbor Observatory, Michigan, Dr. P. A. McNally, director of the Georgetown College Observatory, Dr. F. K. Richtmyer, of Cornell University, Dr. I. C. Gardner, National Bureau of Standards and Mr. J. W. Willis, of the Naval Observatory, accompany the expedition and assure a wealth of valuable eclipse experience. The party will be completed by a naturalist (a naval surgeon), and a photographer from the National Geographic Society.

The spectrum of the chromosphere and corona will be photographed by Dr. Mitchell and Dr. Curtis respectively. Dr. McNally will photograph the corona through a variety of filters, while Dr. Richtmyer will measure the total light of the corona. Colour photographs of the corona will be attempted by Dr. Gardner, who will repeat some of the photographs secured by him in Siberia last June (*see* NATURE, March 13, p. 434). Time observations of contacts will be made by the observers from the Naval Observatory.

This party will be taken from Honolulu by the U.S. Navy mine-sweeper *Avocet* early in May. They may have a difficult time in preparing for the eclipse. We can only hope that the good weather, which has generally, though not invariably, attended Dr. Mitchell and Dr. Curtis, will hold for both parties on the morning of June 8 next.

A Japanese expedition, under the leadership of Prof. I. Yamamoto, of the Kwasan Observatory, Kyoto, will proceed to the coast of Peru to observe the eclipse of next June at sunset. The other members of the party are Prof. T. Araki and Messrs. Y. Sibata and M. Horii. The programme includes photography of the corona and of the spectra of the chromosphere and corona, photometry of the corona and some geodetic observations. The equipment will include some cinematograph cameras.

F. J. M. S.

Radium Treatment in Great Britain

RADIUM treatment is an established medical service in Great Britain, as may be gathered from the reports which are issued from year to year, especially by the four important organizations which have the responsibility of encouraging its practice and of helping research bearing upon its many problems. These organizations are the National Radium Commission, now in its eighth year of existence, and King Edward's Hospital Fund for London, both of which are primarily concerned with treatment; the British Empire Cancer Campaign and the Medical Research Council, whose interests in the subject are primarily research, their common matters of discussion in the first instance usually being referred to a joint Radiology Committee. The allocation of radium by these four organizations at present exceeds 40 grams of radium element.

The seventh annual report of the Radium Commission[*] includes a statistical report of 47 pages which teems with interest. It being no longer a question whether radium is of *any* use in the treatment of cancer, one of the first questions which the Commission has tried to answer is how much use it is. To this end, an elaborate plan was laid, and the first fruits of this are now at hand. The present report gives the 3-year and 5-year results of radium treatment of five common sites of cancer, namely, breast, cervix uteri, lip, tongue and floor of mouth. From the data contained in thirty-nine tables it is now possible to obtain the answer to almost any question that can normally arise concerning the probable results of treatment, as practised throughout the country. The report is based upon an analysis of the records of more than 5,600 patients, and the hospitals from which the patients have been drawn are widely distributed throughout the whole of Great Britain.

---

[*] Seventh Annual Reports of the National Radium Trust and Radium Commission 1935–1936 including a Statistical Report. (Cmd. 5342.) Pp. 91. (London: H.M. Stationery Office, 1937.) 1*s*. 6*d*. net.

Little is said throughout this statistical report of the efforts which the Radium Commission made in its preparation of suitable clinical record sheets and statistical cards so as to ensure that the right kind of information was eventually received from its National and Regional Centres, preferring to report upon the fact that the accuracy of this material has shown signs of steady improvement. How loyally these Centres have contributed in the work of the follow-up of patients is shown by the fact that only 3·9 per cent of the total patients has been lost sight of.

The spirit of co-operation is further shown by the arrangement made by the authorities of King Edward's Hospital Fund, that the data from hospitals receiving allocations of radium from the Fund should be put at the service of the Commission.

Though radium is used in the treatment of other diseases, its outstanding medical interest is its use in cancer, and one of the chief difficulties in the preparation of data is to agree upon some common and acceptable method of classifying the various stages of the disease. This had already been done in 1929 for uterine cancer by the Radiological Sub-Commission of the League of Nations Health Organization, but for no other sites. The Commission therefore undertook this for the other sites of cancer already mentioned.

The general scheme of the report follows the same lines for each site under investigation; the completeness of the information may be gathered from the following tabular headings: percentage net survival rates; patients who have died classified according to cause of death; percentage three-year net survival rate according to whether or not a histological examination was made; number of patients treated by different methods or combinations of methods; percentage net survival and symptom-free rates at three and five years after treatment according to method of treatment and stage of disease; age distribution of patients; three-year net survival rate according to age of patient and stage of treatment.

In only one of the five groups, namely, carcinoma of the cervix uteri, is there any appreciable difference in the three-year net survival rate according to whether or not a histological examination was made. Table 13 is here reproduced; while no explanation is available, it may be suggested that the failure to have this valuable histological evidence was only one indication of inadequate treatment.

TABLE 13 CARCINOMA OF CERVIX.

Percentage three-year net survival rate according to whether or not a histological examination was made

Stage of Disease	Histological examination made	No histological examination
I	63 4 (304)	50 8 (66)
II	51·2 (440)	35·7 (99)
III	32 4 (678)	15·5 (120)
IV	15·0 (266)	5·0 (85)
All stages	40·0 (1,688)	24·8 (370)

Numbers in brackets are the number of patients.

The dangers of malignant disease are two-fold; primarily the growth with its local spread, secondarily its extension into other structures of the body. The extent to which the latter adds to the difficulty of radiological treatment is well shown in the section of the report devoted to carcinoma of the tongue. The patients were classified according to the stage of the disease as follows:

I. Primary growth limited to the tongue: (*a*) glands not involved; (*b*) glands involved.

II. Primary growth limited to the tongue and floor of mouth: (*a*) glands not involved; (*b*) glands involved.

III. Primary growth has spread from the tongue to other structures within the mouth: (*a*) glands not involved; (*b*) glands involved.

This should be read in conjunction with the following data contained in Table 27.

TABLE 27.—CARCINOMA OF THE TONGUE.

Percentage net survival rates from all methods of treatment in which radium was employed.

Stage of Disease	Net Survival Rate at:	
	3 years	5 years
Ia	49 7 (339)	26·2 (83)
Ib	12·6 (310)	5 1 (85)
IIa	39·6 (143)	18 5 (29)
IIb	11 5 (265)	11·1 (57)
IIIa	31 0 (47)	— (6)
IIIb	7·5 (136)	3·3 (30)
All stages	25·7 (1,240)	13·9 (290)

For those who prefer composite figures, the following data (p. 701) are available, giving net survival rates in percentages.

The impression should not be formed that these patients have been treated by means of radium only; this is far from the case. In breast cancer, for example, no less than 86 different conbinations of methods of treatment come under analysis, in uterine cancer 66, and so on. This arises from the fact that there are three main methods in radium treatment, each of which may be associated with varied surgical or X-ray treatment.

Site	Earliest Stage of Disease		All Stages of Disease	
	3 years	5 years	3 years	5 years
Breast .	70 1	50 0	37 2	24·6
Cervix Uteri ..	61·1	49·4	37 3	31·1
Lip .. .	77·5	77·8*	68 8	53·6
Tongue	49·7	26·2	25·7	13·9
Floor of Mouth ..	62 0	53·6	36 2	31·0

* Small group of patients.

Difficulties in treatment are many, but no sentence in this report brings these difficulties more acutely to mind than the following:

> "The proportion of patients in whom the disease is still localised to its original site and in whom there are no signs of local or metastatic spread when the patient is first seen amount, for all sites investigated, to only 25 per cent. of the patients. The marked difference in the survival rates shows that for these patients the chances of survival are much more favourable than when either local spread or metastasis has taken place."

Of necessity the results of individual centres cannot be gauged when merged into the larger groups, so invaluable for statistical work. From the reports entitled "Medical Uses of Radium" issued for the last fifteen years by the Medical Research Council, this can be done for the centres taking part in its scheme of research. These reports also from time to time show the important results of radium treatment in certain non-malignant gynæcological conditions.

Radium has proved of service in the treatment of cancer, especially when the direction of the medical services has been in competent and inspiring hands. The tendency in treatment is for less interstitial work to be done, giving way to surface and distant applications of radium, the latter involving the use of bigger units, 1-5 grams. There is little doubt that, as the warrant is shown for the use of these bigger units, the country will see to it that the necessary radium is provided.

S. RUSS.

Centenary of the University of Göttingen

From a Correspondent

GÖTTINGEN is celebrating its bicentenary on June 30 of this year. Perhaps no university has maintained so high a standard of learning over so long a period as Göttingen. Among its illustrious professors have been Albrecht von Haller, a man of most varied genius and the first modern physiologist, Gauss, supreme alike as mathematician, astronomer and experimenter, Blumenbach, the humane and wise father of anthropology, the brothers Grimm, begetters of modern scientific philology, whose name is known in every nursery, Wilhelm Weber, associated with the measurement of electrical quantities, with terrestrial magnetism, with the electric telegraph and, along with his brother Ernst, with a multitude of physiological researchers, Ewald, the Hebrew scholar, commonly regarded as the father of scientific biblical criticism, Wüstenfeld, who traced the debt that European science owes to the Arabic-speaking world, and Henle, one of the greatest of anatomists, founder of the science of histology, whose name is attached to more than one structure of the body. These men and their colleagues and successors taught and inspired innumerable English-speaking students.

During the first third of the twentieth century, Göttingen fully maintained its historic standards. Its mathematical disciplines, especially, were held in the highest esteem. The great mathematical-physical group at Göttingen was, beyond all cavil, the most important scientific school in post-War Germany. Members of this school were among the first to re-establish contact with English colleagues after the War, and Göttingen was the first German university to receive English students.

The University of Göttingen was founded by George II of England, and opened on October 31, 1734. Thus an appropriate occasion for a bicentenary would have been the early autumn of 1934. At that time, however, both Germany and her neighbours were still very conscious of the effects of the official massacre, known as the 'clean-up', of June 30 of that year. The number who perished on that day is still not exactly known—the German Government has published no list—but a list of persons of political importance who disappeared about that time contains no less than 1,184 names. Further, it was towards the end of June 1933 that students and "black guards" (S.S. men) secured a great number of books from the University library at Göttingen and burnt them in public without protest from the Rector. Memories are short, but it has been found impossible to secure complete forgetfulness of these events. The German authorities have, therefore, taken the prudent line of associating the day with other events. Last year the Heidelberg centenary celebrations were arranged to culminate on June 30, and this year June 30 is chosen for Göttingen.

Though 1934 might have been more appropriate for the celebration, 1937 is certainly the centenary of important events in Göttingen history. On September 17, 1737, the University occupied new buildings. In 1837, the liberal constitution that had been granted to the Hanoverians a few years earlier, was revoked by their sovereign, Ernest Augustus, son of George III of England. Seven of the most distinguished professors of Göttingen—the famous *Göttinger Sieben*—protested. They were expelled. The displaced professors included some of the greatest scholars of the age. Among them were Wilhelm Weber, the brothers Grimm and Ewald. These three events, therefore, the massacre of June 30, 1934, the burning of the books about a year before, the abrogation of the liberal constitution of 1837 and the expulsion of the professors in the same year, will be in the minds of many on June 30, 1937, when the Rector of the University of Göttingen has bidden guests from universities and learned bodies throughout the world to rejoice with him.

Those who join in the celebrations at the University of Göttingen will ask in what spirit that body interprets learned anniversaries. The question has been answered by its professor of ancient history, Dr. Kahrstedt, in an address at Göttingen on German Empire Day. He explained that that day was :

> "the day to take this vow :— We renounce international science. We renounce the international republic of learning. We renounce research for its own sake. We teach and learn medicine, not to increase the number of known microbes, but to keep the German people strong and healthy. We teach and learn history, not to say how things actually happened, but to instruct the German people from the past. We teach and learn the sciences, not to discover abstract laws, but to sharpen the implements of the German people in competition with other peoples. If the German universities make and keep this vow, then it will naturally come about again that they are the first to be consulted in all cultural and spiritual questions."

These sentiments and this confidence were echoed by the Minister of Education, Herr Rust, at the centenary celebrations at Heidelberg on June 30, 1936. Herr Rust said that "the National Socialist Government has, since 1933, got rid by a series of institutional measures of what was outworn and superfluous in the Universities". We may now therefore glance at these "outworn and superfluous" elements at Göttingen.

In its institute for mathematics, in its institute for theoretical physics, in its two institutes for experimental physics and in its institute for mathematical statistics, there were gathered together at Göttingen in 1932 as active and brilliant a group of investigators as were to be found anywhere in the world. Wholesale dismissals began in 1933, earlier at Göttingen than at any other seat of learning, and they affected especially these institutes which were the chief glory of the University. At the mathematical institute there was only a single survivor, while the other great institutes were also 'cleaned-up'. Of the 238 members of the staff, 52—twenty-two per cent—were displaced. The readers of NATURE may be interested to learn the names of a few of these.

(1) Prof. Felix Bernstein at the time of his dismissal had been on the staff at Göttingen for twenty-five years. He was director of the Institute for Mathematical Statistics which was developed under his supervision. He now holds a chair at Columbia University, New York.

(2) Prof. Max Born has become famous for his work on the quantum theory and on atomic structure and is generally recognized as one of the most distinguished living exponents of theoretical physics. He now holds a chair at Edinburgh.

(3) Prof. Richard Courant is a specially stimulating teacher. He was the chief organizer of mathematical research at Göttingen. He is now a professor at New York University.

(4) Prof. James Franck won the Nobel Prize for physics in 1925 for his experimental confirmation of the basis of the quantum theory. At the time of his resignation he had been an "ordentlicher" professor at Göttingen for eight years. On resigning he wrote that he could not remain silent while his colleagues were being dismissed. Thirty-three professors and lecturers at Göttingen signed and published a protest against his "impertinent resignation", accusing him of "sabotage" ! Prof. Franck now occupies a chair at Johns Hopkins University.

(5) Prof. Hermann Fraenkel is very well known as an Hellenic scholar. He is now professor of Greek at Leland Stanford University, California.

(6) Prof. V. M. Goldschmidt, a geologist and mineralogist of international reputation, was liable to dismissal as a foreigner. He is of Norwegian nationality, having been born at Oslo where his father was professor. Many professors of geology and mineralogy in Germany signed a memorial that he might be retained. He was allowed to stay for a time, but his life was rendered unendurable and work impossible. He was given no sort of protection by the Rector or by the other authorities. He resigned and accepted a chair at Oslo.

(7) Prof. Edmund Landau is generally regarded as one of the great pure mathematicians of our time. His name is specially associated with the theory of numbers and the theory of functions At the time of his dismissal he was director of the Mathematical Institute and had been for twenty-four years an "ordentlicher" professor at Göttingen. He is sixty years of age.

(8) Prof. Otto Neugebauer is one of the most distinguished living exponents of the history of science and especially of Greek astronomy and mathematics. He is now professor of the history of mathematics at the University of Copenhagen.

(9) Miss Emmy Noether had an international reputation. She was widely regarded as the most distinguished woman mathematician of our time and perhaps of all time. Her name is especially associated with the theory of groups. She died in exile in the United States soon after her dismissal.

(10) Dr. Karl Saller, an anatomist who specialized on questions of 'race', was dismissed because he could not teach the official doctrines concerning an 'Aryan race'. Dr. Saller was himself once a Nazi, but he could not endure the limitations laid by the Party on scientific inquiry, and his anthropological knowledge prevented him from accepting its racial doctrines. He resigned and was treated with great severity.

(11) Prof. Hertha Sponer is a distinguished experimenter whose name is associated with the analysis of molecular spectra. She is now professor of physics at Duke University, North Carolina.

(12) Prof. Hermann Weyl was called to Göttingen from Zurich in 1930 to succeed the mathematician Prof. Hilbert for whom the famous Mathematical Institute had been built, partly from Rockefeller funds. Prof. Weyl had difficulties because of his wife's Jewish origin and therefore took the opportunity to leave Göttingen when invited to Princeton. Prof. Weyl is known as a philosopher as well as a mathematical physicist.

In estimating the influence of the new régime on German universities several factors have to be considered :

(1) The actual losses can now be estimated with fair accuracy. The number of teachers known to have been displaced from the universities and seats of higher learning is 1,684 ; that is about fifteen per cent of the scholars of Germany. To this must be added a number of quiet resignations and retirements. The true number of displacements is probably not far from 2,000. No institution has suffered more than the University of Göttingen by the loss of distinguished members of its staff ; and of the universities, only Berlin, Frankfurt and Heidelberg have lost as high a percentage.

(2) The intimidation of the staff has a profoundly unsettling effect on their work. Moreover, a stream of edicts—often of a contradictory nature—constantly pours from the Ministry of Education. Merely to master this mass of 'official German' is a considerable task. The excited and threatening political atmosphere in which all officials must live—and German university teachers are now more than ever officials—militates against careful scientific work. Estimates in all departments are unanimous in reporting a rapid and continuous fall in quality. This fall is somewhat masked, partly by the inclusion of foreign contributions, which are eagerly accepted by German scientific journals, and partly by the output of text-books.

(3) The most deadly enemy of German science is the method of recruitment of the junior teaching staff. There is now in operation a complex apparatus that effectively bars studious, scholarly and objectively minded young men from joining the junior staffs of German universities. Beginning in the elementary schools and ending with 'habilitation', there is a whole series of searching tests of the opinions, the political reliability and the military value of every academic aspirant. Two recent orders must suffice to illustrate these points.

The official *Völkische Beobachter* issued a statement on April 5, 1937, that sword practice would shortly become compulsory in all the universities. The statement ends thus :

> "Soon, when we hear again the words of command for the duel in the universities and seats of higher learning, and the arms clash again, we shall know that this bodily exercise that belongs equally to the whole nation, is no longer a class distinction as formerly. And everywhere, when a man challenges the offender of his honour, there will no longer be any such thing as academic privilege, but only the manly settling of an offence against honour for every Folk-Comrade trained to arms."

The following decree of the Minister of Education was issued last month in his official journal :

> "*Disciplinary Procedure against Student Leaders.* I request the Rectors of the German Universities that in future, *before* initiating disciplinary procedure against students who hold office in the German Students' Federation or in the Nazi Students' Union, they report to me with the presentation of the evidence and await my decision."

Thus not only are students being selected at the universities for qualities irrelevant to their scholarship but also the universities themselves are being deprived of their disciplinary power. The whole organization of the German university from rector to student is on a new basis. Göttingen ceased in 1933 to be a scientific centre. On June 30, visitors to Göttingen will celebrate a unique series of losses of learning, liberty and life.

Obituary Notices

Brigadier-General Sir H. C. L. Holden, K.C.B., F.R.S.

SIR HENRY CAPEL LOFFT HOLDEN died on March 30 at the age of eighty-one years. He was a man of great vision, a distinguished scientific investigator, mathematician and mechanician. His was a versatile and inventive mind which knew no bounds. No matter what the nature of the work or investigation he undertook, he would bring to it an active, keen brain, with freshness of outlook and freedom from the trammels of past practice. He sought to improve on what already existed, or to develop something fresh which would be more effective in its application.

It is now nearly forty years since I came into contact with Sir Capel Holden, when he was superintendent of the Royal Gun Factory, Woolwich Arsenal. He at once impressed me as a man of forceful character and of considerable scientific attainment.

At a time when electric transmission in connexion with machine tools was almost unknown, Holden was a pioneer and applied his talents to the development of an electric drive on machines for the manufacture of guns. He introduced an ingenious magnetic chuck which has had many applications and is still in use in the Royal Arsenal. These pioneer efforts were the forerunners of many of the electrical devices applied to up-to-date machinery of the present day.

Prior to my contact with him, Holden had already shown a flair for experimental work and electrical investigation. Nearly fifty-five years ago when in India, he was given permission to erect a special area line, and the knowledge gained by his tests led to his appointment in the Royal Arsenal, Woolwich, in 1885 as Captain Inspector in the Royal Gun Factory, and afterwards as Inspector of Warlike Stores in 1888. But his innate genius for experimental and electrical work did not find full scope for his abilities until his appointment in the experimental establishment in the Royal Arsenal. Here he built up a reputation as one of the foremost ballistic experts and authorities on gun construction. Among other scientific developments, he modernized and improved the Boulengè chronograph for measuring velocities of ammunition in flight.

At this time, Holden was continuously at work designing instruments and making experiments in internal ballistics and investigating the burning of explosives, which materially improved our knowledge of such matters and led to great savings in expenditure. The most important results of his experiments were embodied in the rules and methods for calculating explosive charges and ballistics in guns. These had formerly been a matter of guesswork, and were actually obtained by trial and error. Since his methods have been in use, it has been easy to predict what are the best proportions of the charge of projectile and what ballastics can be obtained as a maximum from a given gun under different conditions. For his special work in connexion with the foregoing investigations he received a substantial reward from the Government.

In 1899, Holden was appointed superintendent of the Royal Gun Factory, Woolwich, and acted as Chief Superintendent of Ordnance Factories for a short period in 1903. When the Royal Gun Factory and the Royal Carriage Departments were amalgamated in 1907, he was selected for the joint post, which office he held until his retirement in 1912. During this period, he completely revolutionized safety devices for guns and introduced many ingenious mechanical and electrical devices. Standing to his credit are many inventions and improvements which evolved from the fertile brain of this scientific investigator and born engineer. He again received a substantial reward from the Government for these further services. For many years, Sir Capel served as an official member of various committees, where his wisdom and advice were greatly sought after.

Yet, amid all the activities directly connected with his official post, Holden's inventive powers sought other fields of investigation. His energies directed him to take up motor engineering, in which he sought to perfect an engine for use in a motor-car and motor-cycle, and a four cylinder 'Holden' motor-cycle of his design, which embodied many ideas in advance of the then current practice, was put on the market. In 1905 he became chairman of the Royal Automobile Club, and afterwards, in 1921, chairman of the Royal Aero Club.

Holden's scientific attainments brought him early to the fore-front as a clear-thinking investigator of a high order. This was recognized by his election to the Royal Society more than forty years ago. He was called from his retirement to be Director of Mechanical Transport at the War Office in 1914, and served at the Ministry of Munitions in 1917–18. For his further services to the Government he was honoured by His Majesty the King by being made a Knight Commander of the Order of the Bath.

Sir Capel's services to electrical science and its application to electrical and mechanical development were clearly recognized by his election to full membership of the Institution of Electrical Engineers, and afterwards he became a vice-president of the Institution. He was also a vice-president of the Royal Society of Arts and in 1927 president of the Radio Society of Great Britain.

It is difficult, if not impossible, to estimate with any degree of accuracy, the value of the service Sir Capel rendered to his country and to the armament and engineering industries; but it may be said of him, as of other great engineers, that he wrested from Nature some of her secrets and used them for the benefit and convenience of mankind.

FRANCIS CARNEGIE.

Prof. S. Young, F.R.S.

PROF. SYDNEY YOUNG, after a brief illness, died in a nursing home in Bristol on April 8 at the age of seventy-nine years. He received his training in chemistry at Owens College, Manchester, and the University of Strasbourg, and in 1882 was appointed lecturer under William Ramsay in University College, Bristol. From that date until Ramsay went to London in 1887, he and Young published a series of joint papers dealing with such subjects as evaporation and dissociation, the properties of water and steam, and the thermal properties of many liquids.

It was not, however, until Young was appointed to the chair of chemistry in Bristol in 1887 that the long series of investigations commenced which established his reputation as one of the leading physical chemists of his day. The earlier papers dealt with the generalization of van der Waals, the determination of critical volume and density, the law of Cailletet and Mathias, the thermal properties of iso-pentane, *n*-pentane and *n*-hexane, and the boiling points of different liquids at equal pressures.

The preparation of the substances Young investigated necessitated a new type of still head, and after much experimental work, those he devised and made himself were so remarkably efficient that he was able for the first time to obtain liquids of an exceptional degree of purity, and with them he was able to investigate in a way that had been previously impossible the nature of the lower boiling fractions of American petroleum. The determination of the vapour pressure and boiling points of mixed liquids, such as the lower alcohols and water, and the alcohols, benzene and water, led to the 'azeotropic' method for the preparation of absolute alcohol, which proved of considerable technical importance.

The whole of this fundamental work was characterized by a very high degree of accuracy, and demanded great experimental skill and extraordinary patience. Dr. Young gave an account of this work in "Fractional Distillation", published by Messrs. Macmillan and Co., Ltd., in 1903, and in a second enlarged edition called "Distillation Principles and Processes" in 1922.

It was whilst Young was in Bristol that he was elected to the Royal Society in 1893. In the laboratories there the numbers of students were small, and in consequence both administration and teaching left him ample time for experimental work. Although some of his communications were joint papers with Miss E. C. Fortey, Dr. G. L. Thomas, Dr. F. Francis and Prof. F. R. Barrell, by far the larger number were the result of his own individual work. When he accepted the invitation to the chair of chemistry at Trinity College, Dublin, in 1903, he found the conditions there entirely different, and the large amount of teaching and administration made such heavy demands on his time that his experimental work suffered, although he still made contributions to various societies.

Young was president of Section B (Chemistry) of the British Association at the Cambridge meeting in 1904. "Stoichiometry" was published by Messrs. Longmans, Green and Co., Ltd., in 1908, and a second edition in 1918. In 1917 he was elected one of the vice-presidents of the Chemical Society, and between 1920 and 1925 he served on the Advisory Council of the Department of Scientific and Industrial Research. His work for Trinity College, Dublin, was highly appreciated, and a leading article in the *Irish Times* when he retired stated that "he was a proof that Irish and English mentalities are not among the things which resist combination".

Young's connexion with the Royal Irish Academy, of which he was president in 1921–26, gave him an importance in Ireland's intellectual life, and his tact, kindliness and known moderation, together with the able co-operation of his wife, did much to ease a difficult period of transition. On his retirement from Trinity College in 1928, he received a remarkable, and perhaps unique tribute, for on that occasion he was presented with an address containing 210 signatures of old students and eminent men of science from all over the world. They expressed their high appreciation of his work, and wished him many years of leisure. In the last year of his life he was greatly pleased at being elected president of the Manchester University Old Students' Association.

Prof. Young married Grace Martha Kimmins in 1896, and she survives him. They had twin sons, of whom Sydney Vernon was killed in the Great War and Charles Edgar is headmaster of Lincoln School and headmaster designate of Rossall.

JUST at a time when preparations are being made to celebrate the hundred and fiftieth anniversary of the birth of the Czech biologist, Jan Evangelista Purkyně (Purkinje) comes the news that his grandson, Prof. Cyril Purkyně, died in Prague on April 5 after a long illness at the age of seventy-four years. Prof. Cyril Purkyně had been professor of geology and mineralogy at Prague Technical University since 1907, after having taught geology and palæontology at Pilsen from 1895 until 1907. Whilst there, he began his work on local geological cartography and this was extended after his appointment as the first director of the Czechoslovak State Geological Institute in 1919

WE regret to announce the following deaths:

Prof. A. W. Borthwick, O.B.E., first professor of forestry in the University of Aberdeen, and formerly chief research and education officer to the Forestry Commission, on April 19, aged sixty-four years.

Lord Conway, known for his explorations in the Himalayas, Spitsbergen, the Andes, etc., author of many well-known works on exploration and travel, on April 18, aged eighty-one years.

Prof. A. Gravis, emeritus professor of botany in the University of Liège, on January 1.

Sir George Hart, K.B.E., C.I.E., formerly Inspector-General of Forests in India, on April 16, aged seventy-one years.

News and Views

Prof. G. G. Henderson, F.R.S.

THE medal of the Society of Chemical Industry has been awarded to Prof. G. G. Henderson, regius professor of chemistry in the University of Glasgow. The Medal is presented every alternate year for conspicuous service to applied chemistry. Prof. Henderson began a life-long association with teaching in 1884, when he became assistant to the professor of chemistry in the University of Glasgow. He also possesses the unique distinction of having been president of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry. For a number of years, he was one of the secretaries of Section B (Chemistry) of the British Association, in 1905 he became recorder, and in 1916 he was president. Much time and energy has been devoted by Prof. Henderson to the prosecution of original research —mostly in the organic field and particularly the chemistry of terpenes—and to the supervision of the research work of students.

Destruction of the Bed Bug

A PROMISING advance in solving the problem of the destruction of bed bugs is reported in the *British Medical Journal* of February 27, p. 459, by Messrs. S. A. Ashmore, of the Government Laboratory, and A. W. McKenny Hughes, of the Natural History Museum, acting for the Committee of the Medical Research Council. That the evil is a grievous one, although often passed by on account of the unsavoury nature of the subject, can be gathered from conversations with medical officers of health, who have been known to declare that they can identify streets with infested houses from the paleness of the children due to sleeplessness produced by bites. It has been said that in hot weather children are driven from their beds to play in the streets in some quarters during the light night hours. Disadvantages attach to most of the treatments previously tried. Thus hydrocyanic acid in the gaseous form is lethal to the insects and also to their eggs, but the use of this highly toxic substance obviously requires great precautions, especially, for example, in treating a room situated in the midst of tenements. Certain chlorinated aromatic derivatives appeared promising, but were found to act as liver poisons on the animal organism, and presumably on man, if traces were left unevaporated.

THE authors put forward a simpler method with which they have had promising results both in the laboratory and in about two hundred infested houses. It consists in spraying the room at a temperature not below 60° F. with a quantity of fairly high boiling coal-tar naphtha for which a specification is given, the room being thereafter sealed for eighteen to twenty-four hours. It is claimed that this substance is not only lethal to the insects, but is also an ovicide, and that it is not harmful to other animals. The concentration of vapour necessary is well below that of the flash-point of its mixture with air. Research is going on at the Field Biological Station of the Imperial College of Science to determine which of the many constituents of this coal-tar naphtha is specially efficacious, but the above-quoted report points to a remedy, by the careful use of a cheap and easily obtained product. It is greatly to be hoped that this method proves successful, for this social evil is a very great and widespread one.

The Boulder Dam

A LECTURE on the remarkable engineering achievement, known as the Boulder Dam, across the Colorado River about thirty miles south-east of Las Vegas, Nevada, where the river forms the boundary between the States of Nevada and Arizona, was delivered to the Institution of Civil Engineers on April 15 by Mr. John Lucian Savage, chief designing engineer, Bureau of Reclamation, United States Department of the Interior. The Dam has already been referred to in NATURE (Feb. 9, 1935) and the leading particulars will be given in one of a series of articles on "Water Power Developments in the United States", already prepared and awaiting publication. Mr. Savage's lecture was a very detailed account of the engineering features of the undertaking and of the constructional methods employed. It is interesting to note that the four diversion tunnels for the river (which were a necessary provision at the outset of operations) each 56 ft. diameter bore and 4,000 ft. long, were driven through unusually sound monolithic rock, with the result that 1,500,000 cubic yards of excavation in the three miles of tunnel were removed without the use of timbering or roof supports of any sort. "The ideal character of the andesite breccia rock for tunnelling purposes, as evidenced by this record, is one of the marvels of Boulder Dam." The reservoir behind the dam, called "Mead Lake" in honour of the late Dr. Elwood Mead, has a capacity of 30,500,000 acre-feet, of which 9,500,000 acre-feet has been reserved for flood control. This volume of flood storage, combined with the 520,000 cusecs (cubic feet per second) of flood discharge capacity, provides for an estimated inflow into the reservoir of nearly a million cusecs without overtopping the dam. This extraordinary provision for inflow is made in view of the remote contingency of the failure of an upstream dam.

A Film of the Royal Botanic Gardens, Kew

A PRIVATE view of a new 'documentary' film of the Royal Botanic Gardens, Kew, was given to a number of men of science in London on April 14. The film, which was made by Short Film Productions, Ltd., and produced by Mr. Harold Lowenstein with the co-operation of Sir Arthur Hill and his staff, gives a 'cross-section' of the activities of Kew as a public garden and as the centre of economic botany and horticulture in the Empire. The opening views give a picture of the Gardens as seen by the ordinary visitor, followed by sequences showing some of the work that goes on behind the scenes, both out of doors and under glass, in order to keep the Gardens in good condition and to provide a constant succession of bloom throughout the year. The most interesting section of the film from the scientific point of view is that illustrating the work that is carried out in the Herbarium, Jodrell Laboratory and Museums. The process of drying, pressing, mounting and storing botanical specimens is shown in the film in detail, and the method of examining and describing new species is also dealt with. The work of the Jodrell Laboratory consists largely of identifying fragments of plants (roots, stems, leaves, etc.) by microscopical examination, and one of the best sequences in the film illustrates the technique of examining a portion of stalk found in the stomach of a poisoned cow. The film ends with an impressionistic treatment of the part that Kew has played in the foundation and improvement of many of the important agricultural enterprises throughout the Empire. The introduction of Para rubber and cinchona (quinine) from South America via Kew to the East in the middle of last century is illustrated, and more recent instances show that this type of work is still being undertaken. This film will undoubtedly be of value in spreading a knowledge of the great importance of the Royal Botanic Gardens in the botanical and horticultural work of the Empire, and it is hoped that it will obtain a wide circulation, especially among schools and other educational institutions.

Palestine Folk Museum

AN appeal for financial assistance towards the needs of the Palestine Folk Museum, appearing in *The Times* of April 19, should meet with a sympathetic reception from the widespread public in Great Britain and America, which is interested in the history and culture of Bible lands. The museum, which is situated in Jerusalem, was opened in 1936 under a committee formed in the preceding year and composed of representatives of the resident English, Arab and Jewish communities. Unfortunately it has no funds, and its work is carried on by voluntary helpers—no inconsiderable burden, even with a tolerant standard of efficiency. No Government grant has been made towards the expenses of the Museum, nor is it eligible to receive assistance from the funds provided by the Carnegie Corporation to aid the museums of the Empire through the Museums Association, Palestine being a mandated territory. Until something in the nature of an assured income is provided, it will not be possible to appoint a curator, an obvious necessity, or to carry on research. Folk museums now have a recognized and an increasingly important part to play in the record and study of cultural history; but the value to the student, whether archæologist or historian, of a folk museum in a country in the near East, such as Palestine, is exceptional. A prolonged period of little cultural change has preserved peasant arts and industries, with their characteristic implements and appliances, domestic and other, virtually unchanged for many centuries, so that objects can be seen in daily use in the villages, which are identical in form and purpose with finds from Palestinian sites of the Bronze and Iron Ages. This period of comparative immobility is rapidly drawing to a close under the impact of an expansion of population and industry under Western influence.

Science and the Conservation of Food

IN his Friday evening discourse at the Royal Institution on April 16, Mr. T. Macara described some special problems of "Science and the Conservation of Food". While the term 'conservation of food' may be applied to many aspects of the production and handling of foods, he confined himself to problems connected with some common types of manufactured food. The first problems discussed were mould growth and fermentation, crystallization, and absence of jelly property in jam. As regards mould growth and fermentation, Mr. Macara put forward the theory that their prevention depends on the production of a jam having a higher osmotic pressure than that of mould spores or yeast cells, and he showed how this result could be achieved. The jelly property of jams is due to the fruit pectin, and it was shown how the jellifying property of this pectin may be lost or destroyed through lack of knowledge of its properties. Problems connected with the preservation of fruits, vegetables and meat products were then discussed. The British Food Manufacturers' Research Association has found certain bacteria the spores of which show an extraordinary high resistance to heat. Boiling for 8 hours or heating to 230° F. for an hour fails to destroy them. It was pointed out that these times apply to small quantities of materials, and that when larger quantities have to be sterilized it is necessary to know the rate at which heat penetrates the product. The question of food storage in cans is surrounded with difficulties on account of defects in the coating of tin on the cans. A number of cases have been met with where the cans became perforated after three or four months' storage.

Joint Committee on Materials and their Testing

A COMMITTEE having the above title has now been set up by leading technical institutions and societies in Great Britain to act as the British national organization in matters relating to materials and their testing. The need in Great Britain of some means to provide for more adequate co-ordination of the study of materials and their testing has, during the past year, received the earnest consideration of the principal technical institutions and societies which are concerned directly and indirectly with these important subjects. Twenty-two institutions and societies are represented on the Joint

Committee. Essentially, the work of the Joint Committee will be divided into two fields of activity, national and international, of which the former will no doubt be of major importance. As a commencement in this field, the Committee is now engaged in making arrangements for a general discussion on the subject of the notched bar test to be held in Manchester in the early autumn of the present year. The activities of the International Association for Testing Materials in Great Britain are at present entrusted to the keeping of a British Committee, and the latter has agreed that, at the conclusion of the London Congress of the International Association for Testing Materials now being held (April 19–24), the Joint Committee shall take over the representation in Great Britain of all matters connected with the International Association. The first chairman of the Committee is Dr. H. J. Gough, largely through whose initiative the Joint Committee has come into being; the secretary is Mr. C. W. J. Taffs, of the staff of the Institution of Mechanical Engineers, the Council of which has kindly offered the necessary facilities for office work at Storey's Gate, St. James's Park, London, S.W.1.

New Commonwealth Society

THE fourth annual report of the New Commonwealth Society and Institute for the year ended September 30, 1936, refers to the way in which the events of the year have emphasized the soundness of the thesis of an equity tribunal and an international police force which the Society was created to advocate, and the report indicates that the New Commonwealth Society is rapidly gaining ground. Forty-four countries are now represented in the membership, which including the international members shows an effective increase of 252 on the year. The position of the group associate membership is less satisfactory. In addition to the publication of the journal and numerous pamphlets during the year, the British Section has initiated a scheme for a "Writers Panel" to develop publicity in the Press. Brief reviews of the activities of other national sections are included in the report. The section dealing with the New Commonwealth Institute outlines the progress of collective research on procedure for peaceful change, a basis for which has been provided by a report prepared by Prof. K. Strupp dealing with the possibility of an international peace convention and peace charter. A department for collective research on the organization of some form of international force has been initiated under Capt. E. Abraham, and similar activity has also been initiated on the reform of the League of Nations. Detailed proposals have already been forwarded to the members of the Advisory Research Committee and to the Foreign Offices of all States members of the League. A further development in the year is the organization of an information department.

Additional Food for the Special Areas

A MEMORANDUM on the Special Areas Bill dealing with the provision for additional food, etc., for mothers and children in distressed areas has been submitted to the Prime Minister by the Children's Minimum Council. The memorandum submits evidence of the inadequacy of incomes in distressed areas based, in respect of food, on figures given in "A Revised Estimate of the Poverty Line" by R. F. George (*J. Roy. Statistical Soc.*). The figures indicate broadly the increasing extent to which the incomes of the unemployed fall below the requirements for health as the size of the family increases. Other evidence of the lack of nourishment of mothers and children in these areas is presented, and the limitations of the present provision by local authorities in England and Wales in consequence of the inability of local rates to support it are also reviewed and discussed. The memorandum urges that the Government should provide in the forthcoming Bill for grants from the national exchequer to local authorities in the Special Areas to cover the whole cost of the supply of free milk to all children in public elementary schools and to scholarship children in secondary schools; the supply of free school meals to all children belonging to families where the amount available for food falls below a scale to be determined by the Ministry of Health; the supply of free boots to school children in such families; and the supply of free milk to expectant and nursing mothers and to children under school age in such families.

Lancashire and Cheshire Fauna

THE twenty-second report of the Lancashire and Cheshire Fauna Committee, just issued, which covers 1935, is probably the most useful publication of the Committee apart from its Check List. It deals chiefly with vertebrates, and in addition to the records of the occurrence of rare species, includes detailed tables of the distribution of the woodcock, grey squirrel and great crested grebe in Cheshire, and the pochard, great spotted woodpecker and redstart in both counties. The committee which announces it is also to include the recording of the marine fauna within the three mile-limit in its work, makes an addition of 101 species new to both counties and 25 new to one county, the former consisting of 28 Coleoptera, 20 Diptera, 20 Hymenoptera, 12 sawflies, 8 Acari, 5 Hemiptera, 2 Mallophaga and Neuroptera and 1 each of Mollusca, Lepidoptera, Anoplura and Siphonaptera. The more interesting specific records are: a new colony of Natterjack toads at Storeton, Cheshire; a November golden oriole at Macclesfield; numerous reports of the invasion of crossbills; a meadow-pipit at Heywood, Lancashire, with an abnormal clutch of five sky blue eggs spotted with red, and a magpie that has developed the habit of nesting on the ledge of a steep moorland cliff there; a chiffchaff wintering there, although it does not nest in the district; a December immigration of blackbirds; an investigation of swallow broods showing that 35 broods in Lancashire averaged 4·05 young and 97 broods in Cheshire averaged 4 young; a kestrel taken in Manchester and found to have its plumage and its nostrils so heavily laden with soot that none of the usual parasites inhabited it.

Horticultural Science in France

M. Georges Truffaut lectured to the Royal Horticultural Society in October of last year, on the experiments on manuring, pest control and microbiology of the soil, which have been carried out under his direction at Versailles. The text of this lecture appears in the Society's *Journal* (62, Pt. 3, March) and portrays results which are in sufficient accord with the findings of research institutes in Great Britain to warrant thankfulness, and yet are original enough to provide great stimulation. M. Truffaut and his colleagues have shown that only when the nitrogen, phosphoric acid and potash are combined upon a basis of their atomic weights will the soil yield its fullest increase in response to artificial manures. The insistence of the earlier agricultural chemists on the necessity of lime for the growth of most crops is countered vigorously by the workers at Versailles, who find that the presence of calcium ions is often undesirable in garden soil. The most welcome contribution of the lecture to the science of pest control is perhaps the description of a new spray fluid known as 'Elgetol'. This is a mixture of a synthetic yellow dye with wetting agents. It has a milder action upon the tree than lime sulphur or tar oil winter wash, but it is quite effective against the overwintering eggs of various insect pests. Workers at the Versailles laboratories have established the fact that soil bacteria can obtain their energy exclusively from carbohydrates and organic salts excreted by the root-hairs of plants. "Living green plants are thus the main source of energy for soil micro-organisms." The lecture also reviewed a wider field of work than the results here mentioned; the sections on calcium metabolism and the control of pests during winter are most informative.

The Post Office and Broadcasting

IN the *Journal of the Institution of Civil Engineers* of March, a report is given of the interesting discussion of a recent paper by Sir Noel Ashbridge on broadcasting. Sir George Lee pointed out that the Post Office acts in several ways as an auxiliary to broadcasting. An important function which it fulfils is reducing the interference which many listeners experience on their wireless sets from electrical machinery. Last year, it investigated 40,000 cases of interference. The total circuit mileage used by the B.B.C. in the P.O. network last year was about 6,000. A large number is also in use for Continental broadcasts. Every country in Europe has now these special circuits, and they are often used for the broadcasting of special events. It is estimated that if 80 per cent of the mains-operated receivers were in use during some important event, such as the coronation, when most people switched on their receivers, the load on the grid system due to this cause alone would be 250,000 kilowatts. The annual consumption of receivers is about 270 million units, quite an appreciable fraction of the load on the grid. Another interesting statistical fact which Sir George Lee gave was in connexion with the three short-wave and one long-wave station which work to America every day. Several hundred kilowatts are radiated from Great Britain towards America but all the power picked up in America would be only sufficient to raise a fly seven inches high in one year. On land-lines, amplifiers are put in at about every fifty miles and there is therefore a large number of amplifying stations between Great Britain and San Francisco. Each amplifier receives such feeble signals that they are just distinguishable from the inherent noise in the circuit, and it amplifies them only sufficiently for the signals to be received at the next station; yet the total amplification received in that repeated process is 10^{156}, a number inconceivably great!

Electric Locomotives for the Natal Railways

FROM the Metropolitan-Vickers Electrical Company's *Gazette* of March 1937, we learn that during the year 1935 it had received orders for twenty-five new 1,200 h.p. electric locomotives for the railways of Natal from the South African Government. The new locomotives had become necessary because of the increased traffic and the doubling of the route mileage. The company had already supplied ninety-five locomotives which had been in constant service in Natal for terms varying from nine to twelve and a half years. The line from Glencoe to Pietermaritzburg is very hilly. Glencoe is situated near the centre of the Natal coal-field, and the transport of coal to Durban constitutes a large part of the traffic on the line. Power is supplied from Colenso through a three-phase 88,000 volt transmission system. The new locomotives differ from the original ninety-five in many details, but they are suitable for multiple unit working in combination with any of the ninety-five original locomotives. Each locomotive is of 1,200 h.p. capacity with four axles each driven by a 300 h.p. traction motor. The auxiliary machines in each locomotive consist of an air compressor, an exhauster and two motor generators of 16 kW. and 28 kW. capacity respectively. The compressor supplies compressed air for the operation of the locomotive brakes. The exhauster produces the vacuum for the train brakes. Of the many improvements embodied in the new locomotives the most important are in the control gear and the pantagraphs for collecting the current. The latter work with a line pressure of 16 lb. as against the original 26 lb. and weigh about 400 lb. less. They can now be raised to the collecting wire without mechanical shock, and similarly there is no shock when lowered to the roof.

Recent Solar Activity and Auroras

A NOTE received from MM. Eigenson and Gnevishev of the Pulkovo Observatory directs attention to the high degree of sunspot activity on and about January 31 last (when the Tashkent Observatory recorded a total spotted area of 4000 millionths of the sun's hemisphere) and a series of auroras which were extensively observed from the U.S.S.R. between January 31 and February 3. The solar activity and associated terrestrial phenomena (including the aurora observed in England on February 3) have been described in NATURE (Feb. 6, p. 228; Feb. 13, p. 277; Feb. 27, p. 375; and April 17, p. 680).

The Royal Veterinary College and Hospital

THE new governing body of the Royal Veterinary College has now been set up according to the constitution granted by the new Royal Charter of 1936, by which its name has been changed to the Royal Veterinary College and Hospital. The government of the college is now vested in a court of governors and an executive council. The Duke of Gloucester is president of the court, which consists of eighteen members nominated by the Royal College of Veterinary Surgeons, the Royal Agricultural Society of England, the National Veterinary Medical Association, the County Councils Association, the Medical Research Council and the Corporation of London.

Colonial Officers and Scientific Research

A FURTHER series of grants have been made by the Trustees of the Carnegie Corporation of New York to the Secretary of State for the Colonies to enable selected officers of the Colonial Service to spend a period of absence from their official duties in study, research and travel. Those who have received grants include the following: H. L. Collett, agricultural and soil erosion officer, Basutoland, for the purpose of investigating methods for the prevention of soil erosion in the United States; H. R. Phillpotts, assistant superintendent of public works, Jamaica, for a course of study in water purification and chlorination in the United Kingdom, and in sanitary engineering; W. Fotheringham, veterinary research officer, Kenya, for a course of study in pathology and bacteriology at the University of Edinburgh, and at the Royal Veterinary College, Camden Town, particularly in relation to the respiratory diseases of sheep; W. C. Gee, assistant engineer, Wireless, Posts and Telegraphs Department, Malaya, for the study of short-wave telephony transmission and ultra-short wave transmission and reception at various institutions in the United Kingdom, in the United States, and elsewhere; A. G. Beattie, agricultural officer, Nigeria, for a visit to India for the purpose of studying peasant husbandry, dairying and cattle breeding, and irrigation from wells; H. M. O. Lester, deputy director of Sleeping Sickness Service, Nigeria, for visits to the Congo, Tanganyika, the southern Sudan, and other parts of Africa, to study methods of sleeping sickness control; J. D. Martin, assistant conservator of forests, Northern Rhodesia, for a course in sylviculture and ecology at the Imperial Forestry Institute, Oxford; J. G. M. King, district agricultural officer, Tanganyika, for a visit to Nigeria to study methods of mixed farming introduced in that colony; R. A. M. Mackay, assistant inspector of mines, Tanganyika, for a course of study connected with the ore bodies of the Lupa Gold Field at the Royal School of Mines, London; A. C. G. Palmer, science master, Grenada Boys' Secondary School, Windward Islands, for a course in education with particular reference to agriculture.

Announcements

LIEUT.-COLONEL J. H. M. GREENLY has been elected chairman of the British Non-Ferrous Metals Research Association in succession to the late Mr. Thomas Bolton.

PROF. L. A. ORBELI of Leningrad, who is in charge of the late Prof. Pavlov's laboratories, has been appointed a member of the Permanent International Committee of Physiological Congresses in succession to Prof. Pavlov.

SIR HUMPHRY ROLLESTON has been appointed chairman in succession to the late Lord Moynihan of the Medical Board of the Eichholz Clinic, 204 Great Portland Street, W.1, which employs a staff of blind chartered masseurs, and is administered by the National Institute for the Blind.

THE February issue of *Forschungen zur Alkoholfrage* is dedicated to Dr. Emil Abderhalden, professor of physiology in the University of Halle, on the occasion of his sixtieth birthday.

THE Health Section of the League of Nations has nominated Prof. Giuseppe Bastianelli, director of the Institute of Malariotherapy at Rome, as president of the Special Committee for Malaria.

THE second Rumanian Congress of Radiology and Medical Electricity will be held at Cluj on May 21–23 under the presidency of Prof. Negru. Further information can be obtained from the secretary, M. Hananut, Calea Motitol 7a, Cluj, Roumania.

THE first International Congress of Infantile Psychiatry will be held at La Maison de la Chimie, 28 rue Saint-Dominique, Paris 7^e on July 27–August 1. Further information can be obtained from the treasurer, M. Gimbert, 11 rue Duroc, Paris 7^e.

THE twenty-sixth Congress of the German Society for Historical and Social Medicine will be held at Breslau on May 12–14, the subject for discussion being the present state of our knowledge of electropathology. Further information can be obtained from Prof. Gerhard Schrader, Lahnstrasse 9, Marburg.

AN International Congress for a discussion on short waves in physics, biology and medicine will be held in Vienna under the honorary presidency of Dr. Arsonval, Marconi and Zonnek on July 12–17. Further information can be obtained from the Secretariat, Alserstrasse 4, Wien IX.

THE Paris laboratory known as "La Biothérapie" has founded a Besredka prize of 15,000 francs for an essay on the therapeutic applications of local immunity. The first award will be made in June 1938. Further information can be obtained from La Biothérapie, 5 rue Paul-Barruel, Paris XV^e, before December 31.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 720.

Correspondents are invited to attach similar summaries to their communications

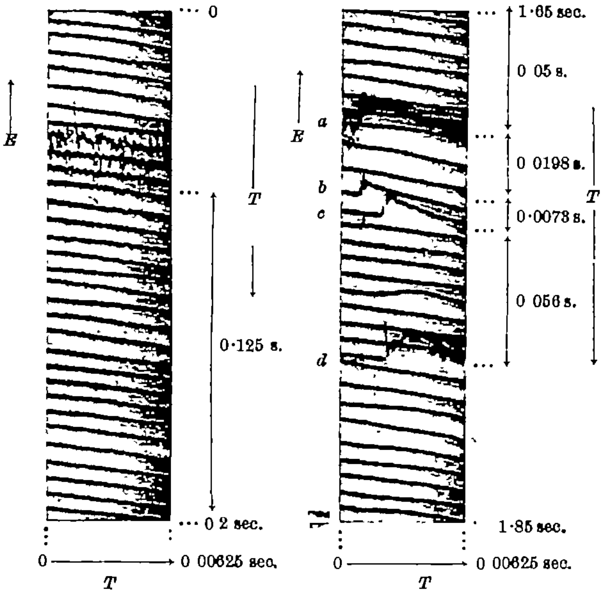
Atmospheric Disturbances due to Thundercloud Discharges

It is generally recognized that the phenomenon of lightning is extremely complicated, and many attempts, notably by Schonland[1], using a special camera, have been made to analyse and classify lightning flashes.

The problem has been attacked in another way by the study of the variations in the earth's electric field due to the lightning discharges. I have already described in Nature[2] an automatic cathode ray oscillograph photographic method of recording these variations. In that work, as in similar observations on field changes made by others, it was recognized that the inherent limitations imposed by the particular time-scale employed resulted in the observer's interest being centred on a part rather than on the whole phenomenon. A convenient cathode ray oscillograph photographic method has now been developed to make a continuous record of all the electric disturbances resulting from thundercloud discharges over a period of seconds, yet providing sufficient resolution to separate pulses of only a few micro-seconds duration.

A linear time-base is employed to produce a horizontal deflection of the cathode ray fluorescent spot; the field changes produce a vertical deflection, while the photographic film is moved at right-angles to the time-base deflection at a speed of 16 cm./sec. In this way a trace of saw-tooth form is obtained with the wave form of the field changes superimposed in time order of arrival, and the records give the total duration of the whole discharge as well as that of the separate lightning strokes. The advantage of this method is apparent, for, to obtain the same resolution by a continuous film time base alone, the film speed would have to be 1·6 metres per second.

An example of a complete record of the atmospheric disturbance occurring during a thundercloud discharge is shown in Fig 1. Portion *A* extends over 0·2 sec. and after an interval of 1·45 sec. is followed by the further phenomenon of the type shown in Fig. 1 *B*. The advantages of this continuous recording are again illustrated since in Fig. 1 *A*, we see the extraordinary phenomenon of a volley of discharges. followed in Fig. 1 *B* after a quiescent interval of 1·625 sec. by the main lightning discharge. This is seen to be analysed into a series of pulses essentially different from the previous ones, but presumably to be correlated with the intermittent lightning phenomenon photographed by Schonland. In Fig. 2 is illustrated part of a volley of discharges of the type already noted in Fig. 1 *A*. The whole disturbance had a duration of 2·3 sec. and in this case there was no indication of any succeeding intermittent lightning discharge. These examples of the results were obtained on Friday, June 19, 1936, between 11 p.m. and 1 a.m., when an extremely active storm crossed London from the south.



(*A*) (*B*)

Fig. 1.

Now it is to be presumed that the extended phenomenon shown in Figs. 1 *A* and 2 is the type of brush discharge so often observed in an active cloud as a prolonged flicker or glow. Although this does not produce the large and rapid change in the electric moment of the cloud charge that the lightning flash does, it is, nevertheless, effective in radiating a long series of electromagnetic waves of peak value and duration sufficient to cause considerable interference in radio receivers. It is interesting to note in this connexion the aural observations of Ashmore[3] and Howard[4], who reported that noise was heard by them in a wireless receiver an appreciable time before the lightning was visible, and also the similar observations of Fyson[5] and Coursey[6] recently mentioned in Nature.

Turning now to the main lightning discharge illustrated in Fig. 1 *B*, the successive pulses *a*, *b*, *c*, *d*, represent partial discharges. It will be noted that the main change of field in *a* is accompanied by a characteristic series of perturbations of decreasing intensity which is usually followed immediately by a rapid intense discharge. No case has so far been recorded of this particular process *a* preceding any of the subsequent discharges *b*, *c*, *d* of the group. The perturbations are evidently due to radiation from the successive 'steps' of the 'stepped leader' pre-discharge mechanism always found by Schonland to initiate such a series of lightning flashes. A detailed analysis shows that the 'steps' are separated by an interval of between 30 and 100 microseconds, their quasi-period corresponding to a wave-length of between 15 and 30 km. Also, during this pre-discharge process, a considerable cloud charge is moved of sometimes even greater magnitude than that caused by the main lightning discharge, and evidently produces the rapid localization of high potential gradients by which the subsequent discharge is initiated.

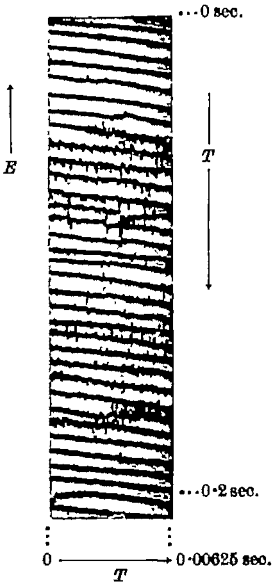


Fig. 2.

In Fig. 3 is shown the type of radiation field change resulting from the pre-discharge and main discharge of a distant lightning flash. This discharge was not preceded by the volley, and it must be emphasized that there is not sufficient evidence at the moment by which it can be asserted whether the volley of discharges is the usual or rare precursor of the lightning flash.

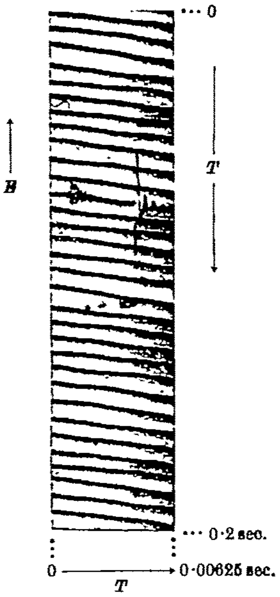

Fig. 3.

A careful study of many such records brings to light a number of interesting features concerning thundercloud phenomena which will be discussed in a subsequent paper.

Chemical Detection of Helium formed in Beryllium by Gamma Rays

Some time ago, we showed[1] that micro-analytical methods are sensitive enough to identify spectroscopically and to measure the helium artificially produced by slow neutrons in boron. This reaction

$$^{10}_{5}\mathrm{B} + ^{1}_{0}n \rightarrow ^{7}_{3}\mathrm{Li} + ^{4}_{2}\mathrm{He} \qquad (1)$$

has been fully investigated by physical methods[2], so that chemistry can merely help in its quantitative study; but there are other processes of artificial disintegration where apparently at present only microchemical methods can decide between different possibilities.

Since the discovery of the 'nuclear photo-electric effect' by Chadwick and Goldhaber, it is known that gamma rays produce neutrons from deuterium and beryllium[3]; in the latter case the formation either of $^{8}\mathrm{Be}$ or of $^{4}\mathrm{He}$ is to be expected according to the equations

$$^{9}\mathrm{Be} + h\nu \rightarrow ^{8}_{4}\mathrm{Be} + ^{1}_{0}n \qquad (2)$$

or

$$_{4}\mathrm{Be} + h\nu \rightarrow 2^{4}_{2}\mathrm{He} + ^{1}_{0}n \qquad (3)$$

It is equally possible that both reactions take place. Now if reaction (3) occurs to any considerable extent, then we should be able to detect the helium by gas-analytical methods, while in the case of formation of a stable, or slowly disintegrating, $^{8}\mathrm{Be}$, no helium should be found.

In a first, semi-quantitative, experiment, lasting one month, we placed tiny radon sources in holes bored into a lump of 6·6 gm. of beryllium metal. After the decay of 0·6 curie of radon, we dissolved the beryllium in sulphuric acid and, by our micro-method, analysed for helium the 17 litres of hydrogen evolved; we found therein about 2×10^{-8} c.c. In another 8 gm. of beryllium, cut from the same piece but not irradiated, no helium could be detected; this means that less than 5×10^{-10} c.c. was present. The amount of helium which must thus be ascribed to the γ-irradiation is so considerable that it would appear to be formed by the main reaction; for if we assume the γ-rays of radium C′ of 1·8 and 2·2 million volts to be equally efficient, and the cross-section of the beryllium nucleus to be 5×10^{-28} cm.[2], we should expect a quantity of helium corresponding to the order found. Because of the uncertainties in these assumptions, however, we tried to decide by a more exact method whether helium is the main product of the reaction. Should this be so, then the number of helium atoms produced in beryllium would be twice that of the photo-neutrons; this latter figure can be determined from the equal number of helium atoms produced in boron according to reaction (1). With this aim in mind, we repeated the experiment, with larger quantities of radon, arranged as follows.

Into a sphere of metallic beryllium (radius 0·84 cm., weight 4·5 gm.) we drilled small holes towards the centre; in these we inserted glass capillaries (length on the average 6 mm., width 1 mm.) filled with radon. The sphere was placed during the whole irradiation in the pocket of the methyl borate vessel of 7·5 cm. radius, described in our previous paper[1]. Owing to their slowness, about 90 per cent of the photo-neutrons are caught inside this vessel. When, after 8½ months, 4·7 curie of radon had decayed near the centre of the beryllium sphere and the surrounding methyl borate, we analysed both the beryllium metal and the borate for helium; in the first we found $1 \cdot 8 \pm 0 \cdot 3 \times 10^{-7}$ c.c., in the latter $1 \cdot 1 \pm 0 \cdot 3 \times 10^{-7}$ c.c. of this gas. The theoretical ratio 2 : 1 is, therefore, approached closely enough to make it highly probable that the main product of the γ-irradiation of beryllium is ^{4}He, and not a stable ^{8}Be; thus, if reaction (2), and not (3), is the primary step, then the ^{8}Be nucleus disintegrates into two helium atoms with a half-value period of not more than a month.

Our grateful thanks are due to Prof. S. Russ, director of the Radon Department, Middlesex Hospital, London, for kindly supplying the radon tubes; and also to Dr. M. Goldhaber, Cavendish Laboratory, Cambridge, for suggesting the experiment and for helpful discussions.

Dilatometric Ultra-Micro-Estimation of Peptidase Activity

As appears from recent publications of Indian workers (Sreenivasaya and Bhagvat[1], compare also Rona and Fischgold[2]), a considerable volume change is observed in systems in which enzymatic cleavages take place. This volume change may be applied to the estimation of enzyme activity, and the dilatometric methods thus developed possess certain advantages, among which may be mentioned the continuous observation of the undisturbed enzymatic process. While looking around for possible means of refining the histochemical methods previously described (Linderstrøm-Lang and Holter[3]), I came across the falling drop method for the measurement of specific gravity (Barbour and Hamilton[4]), a method which recently was re-investigated and improved by Fenger-Eriksen, Krogh and Ussing[5]. Experience with this method led to the development of a static principle of measurement especially suited for estimation of volume changes in small drops and therefore for micro-estimation of enzyme activity. The following description is concerned only with the application of the method for this latter purpose, but the method may prove useful for the estimation of specific gravity also in other cases.

In a vertical glass tube, 30 cm. long, placed in a water-bath at 30° ± 0·005°, a practically constant specific gravity gradient was produced by mixing kerosene and bromobenzene in varying ratios. The gradient was measured by means of 0·1 c.mm. test drops of known specific gravities. Fig. 1 illustrates a characteristic experiment. The test drops were introduced at the top of the glass tube, a suitable micropipette being used, and fell in the course of ten minutes to the level given on the figure, where they remained practically constant for more than eight hours if the medium was well saturated with an aqueous solution of a suitable water vapour pressure. Their positions were observed in a horizontal microscope with ocular micrometer. The drops of enzymatic reaction mixtures were introduced in the same way and their positions were observed after about ten minutes.

In Fig. 1 the drop *A* (0·1 c.mm.) had the composition: 0·1 *M* with respect to *dl*-alanylglycine; 0·0173 *M* with respect to caustic soda; 0·0333 *M* with respect to phosphate buffer of *p*H 7·4; and it contained a suitable amount of peptidase (extract of pig stomach). During the enzymatic reaction the drop fell—corresponding to a decrease in volume—and its positions at different times were compared to those of the test drops. It reached a final position *A′* when the reaction was completed. Drop *B* contained boiled enzyme but was otherwise identical with *A*. In drop *C* the *dl*-alanylglycine was replaced by *dl*-alanine (0·1 *M*) plus glycocol (0·1 *M*). Both these drops remained constant at their respective

levels. The final position of A (A') is nearly halfway between B and C, in agreement with the fact that *d*-alanylglycine alone is split by the enzyme.

Fig. 2 (Curve I) shows graphically the results of this experiment. The chemical change (appearance of amino groups) during the enzymatic reaction was measured simultaneously in larger samples of the same reaction mixture and calculated as milligrams of amino nitrogen liberated per 0·1 c.mm. (Curve II). Finally, Fig. 3 shows the linear connexion between volume change and liberation of amino-nitrogen, 0·74 c.mm. disappearing per mgm. amino nitrogen formed. This agrees as regards order of magnitude with the volume changes found by Sreenivasaya, Sastri and Sreerangachar[6] for other proteolytic processes.

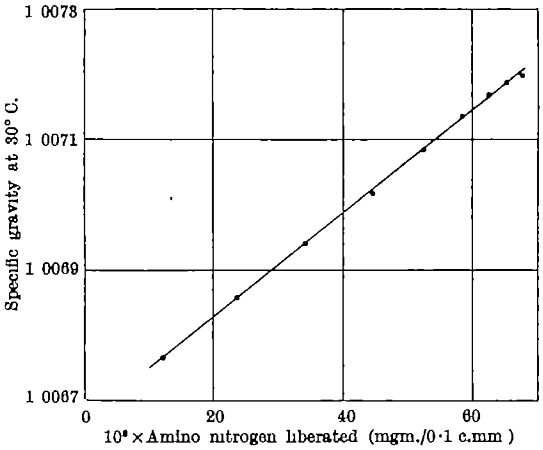

Fig. 3.

The method is being further developed and extended to include other enzymatic processes.

A Presumptive Culicine Host of the Human Malaria Parasites

IN controlled experiments with *Culex bitæniorhynchus* carried out during the past seventeen months, we have observed what we are unable to distinguish from the complete cycle of development of the parasites of benign and sub-tertian (malignant) malaria in laboratory-bred females fed on gametocytes of *Plasmodium falciparum* and *P. vivax* respectively. Presumptive sporozoites accompanied by a stomach cyst were also observed in an insect which was fed on gametocytes of *P. malariæ*, the parasites of quartan fever, those of sub-tertian being also present in much smaller numbers. Ross's black spores were found associated with sporozoites and cysts in several sub-tertian infected, and in one benign tertian infected, insect. These appearances were absent in laboratory-bred controls which had had no blood meals.

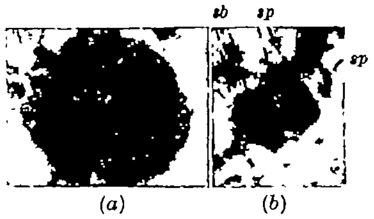

FIG. 1.

PRESUMPTIVE PLASMODIAL FORMS IN LABORATORY INFECTED *C. bitæniorhynchus*

(*a*). UNSTAINED SEMI-CHITINIZED-BLACK PIGMENTED CYST: S.T. INFECTION.
(*b*). BLACK SPORES: B.T. INFECTION, UNSTAINED.

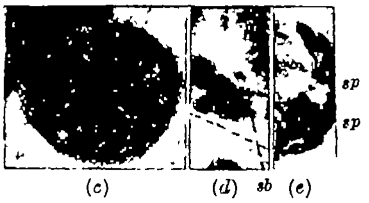

Fig. 2.

CORRESPONDING PHASES IN PLASMODIALLY INFECTED ANOPHELINE

(*c*). STAINED CYST (Q. OR S.T.). AFTER WALCH.
(*d*). UNSTAINED CHITINIZED SPOROZOITES AND 'SPOROBLAST'. AFTER WALCH.
(*e*). BLACK SPORES. AFTER WALCH.
sp = CHITINIZED SPOROZOITES. *sb* = CHITINIZED 'SPOROBLASTS'.

Apart from the fact that culicine mosquitoes have up to the present been held to be inhospitable to human malaria parasites, the interest of these observations is biochemical. Some years ago, one of us pre-indicated *C. bitæniorhynchus* as a possible malaria carrier[1] because it breeds in pure water among *Spirogyra*[2] (on which it also feeds), it being pointed out[1] that some of the most virulent anopheline vectors are likewise found in uncontaminated sources, a fact later confirmed by Covell's tables[3]. The practical, as well as the theoretical, implications of significant correlation between larval environment and power to transmit malaria are of great interest, but since they call for further discussion than is here possible, this together with details of our observations must await publication elsewhere.

We wish to express our obligations to successive Senior Health Officers, Penang, for opportunity to carry out our work, and further, especially to Dr. J. W. Scharff for his critical interest in it.

Biology of a Littoral Mite

DURING my work on the biology of the sea-shore, in East Greenland[1] I made some biological observations of the large, bright red littoral mite (*Molgus littoralis* L.); its distribution is almost circumpolar, especially on the shores of the more northern regions. In East Greenland it was commonly met with on the shore, but extending its domain beyond the shore, being found (also the eggs) up to an altitude of 120 m., most often in sandy and gravelly places. Trägårdh (p. 419[2]) has recorded this and explains it by the non-occurrence of big competing mites. In southern Spitsbergen, it seems to be a strictly littoral form; but in northern Spitsbergen (Low Island, c. lat. 80° N.; Hinlopen Strait) it also extends to the "fjœldmark", which is beyond the shore (Summerhayes and Elton, p. 250)[3].

According to the statements of Sig Thor (p. 97)[4], in southern Spitsbergen (Hornsund), more than one generation seems to develop in the year. This does not hold good for the species in East Greenland. June 25 (at Eskimonœs, lat. 74° 05′ N.), the snow having recently melted, I found eggs in abundance (in good agreement with the figures given by Trägårdh (p. 10, tab. I, figs. 1–2)[5].) They were found especially on the dry sandy shore, in dense cakes under almost every flat stone. Some of the eggs had not hatched, and others were just hatching, the larvæ swarming over the shore. They only had three pairs of legs. Adult individuals were definitely not found. Later in the summer, also in the other localities I visited, only empty egg-clusters and adult individuals were found. So there can be no doubt that the species in East Greenland only winter in the egg. The difference in behaviour from that in Spitsbergen is possibly due to the more severe climatic conditions.

Molgus littoralis is probably feeding especially upon Collembola; though I have seen it suck out the shore fly, *Fucellia ariciformis*, also gnats and even individuals of the same species.

Effect of Unilateral Elimination of the Horizontal Semicircular Canal in the Pike

IN a recent publication[1] it was shown that in the dogfish the sense organ situated in the ampulla of the horizontal semicircular canal is in a constant state of excitation. This activity is maintained in the resting animal in the absence of any obvious external stimulus. The result raises the question as to whether the inflow to the centre of the spontaneous discharge from the ampullary sense ending has any noticeable effect on muscle tone.

In order to investigate this, the horizontal semicircular canal of the pike (*Esox lucius*) was eliminated by severance of the nerve branch supplying the ampulla. The operative technique used in the experiments permitted the elimination of a single canal without any damage to the rest of the labyrinth. A fish in which the left horizontal canal has been eliminated shows a persistent tonic deviation of the eyes towards the side of the eliminated canal, that is, the left eye is deviated backwards and the right eye forwards. This deviation is obviously due to the inflow to the centre of the spontaneous afferent discharge from the remaining right horizontal canal, which is no longer counterbalanced by a similar discharge from the corresponding left canal. The asymmetry in eye muscle tone which causes the forced deviation of the eyes clearly indicates a tonic function of the horizontal semicircular canals.

During clockwise rotation in the horizontal plane, that is, during rotation of the fish towards the side of the intact right canal, the eye deviation is increased and a normal horizontal eye nystagmus follows. During anticlockwise rotation the spontaneous eye deviation is abolished, that is, the eyes return to their normal positions. These eye responses are in full accord with the behaviour of the ampullary sense organ as studied in the dogfish, where the spontaneous activity of the ampulla of the horizontal canal is increased by ipsilateral rotation (that is, rotation towards the side of the intact canal) and decreased by contralateral rotation.

It is of interest that during contralateral rotation the eyes not only return to their normal position but also continue to deviate beyond the 'neutral' point in a way which is characteristic of the slow phase of the eye response of the normal animal during rotation in the same direction. This shows that the centre is capable of responding to a decrease in afferent discharge with the production of a compensatory eye reflex.

The conclusion is therefore justified that a single horizontal semicircular canal in fishes is sufficient to call forth muscular responses to both clockwise and anticlockwise rotation in a horizontal plane. It should be noted that the reflex tests were carried out with exclusion of visual orientation.

A full account of this work will be published in the *Journal of Experimental Biology*.

Anomalous Expansion of Zinc and Cadmium near the Melting Point

THE expansion of bismuth, as was shown by Roberts[1] decreases rapidly near the melting point. This anomaly coincides with the anomalous decrease of volume of bismuth on melting.

The expansion coefficients of monocrystals of zinc and cadmium have been measured in order to ascertain whether the anomaly found by Roberts for bismuth occurs with these metals also, and whether the sign of the anomaly coincides with that of the normal change of volume in melting.

In directions nearly parallel or perpendicular to the hexagonal axis, the expansion of zinc crystals increases rapidly between c. 415° C. and the melting point (419·5° C.). In the neighbourhood of 418°–419° C. (near the limit set by the plastic deformation under its own weight) values of the expansion coefficients reaching 50–100 × 10^{-5} (Fig. 1*a*) were observed.

The same was observed in the case of cadmium for directions nearly perpendicular to the axis (Fig. 1*b*).

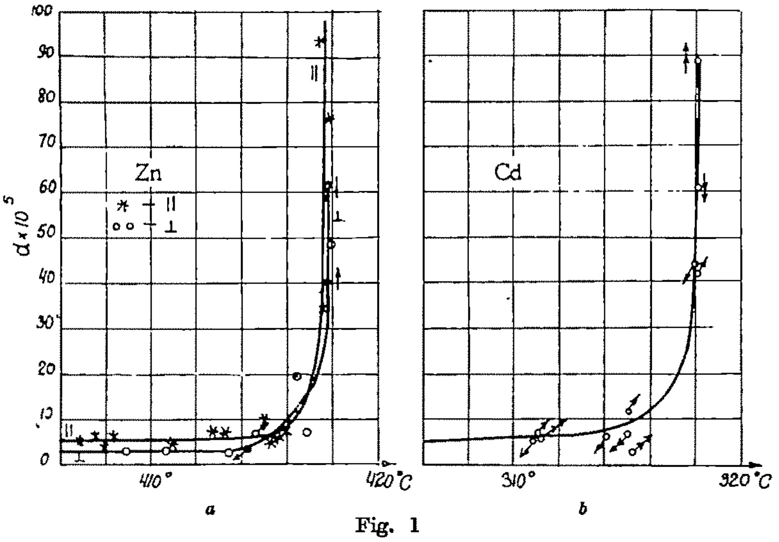

Fig. 1

CHANGE OF COEFFICIENT OF EXPANSION WITH TEMPERATURE FOR ZINC AND CADMIUM. ⇄, FIRST HEATING AND COOLING; ⇉⇇, SECOND HEATING AND COOLING.

It is clear therefore that zinc and cadmium exhibit anomalous expansion near the melting point and that the sign of the anomaly coincides with that of the change of volume in melting.

Induced Radioactivity with Neutrons from Slow Deuterons

IT is of interest, not least from the point of view of possible practical applications, to search for the lower limit of voltages, with which artificial radioactivity can still be produced of intensity sufficient for utilization. We have begun an investigation, in which the induced activity is produced by neutrons, which are produced by slow deuterons. This procedure has the advantage that the small number of neutrons that can be expected will be compensated, at least partly, by the greater efficiency of slow neutrons, due to the slow primary particles.

In our experiments, a beam of positive rays of deuterons was directed on to a mica foil covered with a thin layer of beryllium. The origin of the neutrons is probably the process:

$$^{9}_{4}\mathrm{Be} + {}^{2}_{1}\mathrm{H} \rightarrow {}^{10}_{5}\mathrm{B} + {}^{1}_{0}n\,;$$

but the reaction

$$^{2}_{1}\mathrm{H} + {}^{2}_{1}\mathrm{H} \rightarrow {}^{3}_{2}\mathrm{He} + {}^{1}_{0}n$$

cannot yet be excluded as a possible source of the neutrons. Outside the tube a Geiger-Müller counter of silver was placed at about 10 cm. from the source. It was screened by lead, in order to reduce the number of counts due to the background to 2–3 per minute. The mica foil was irradiated for five minutes with a total current of about 1mA., which was discontinued and the counter set in work. Thus we could measure the activity produced by the neutrons in silver alone.

As regards the half-value periods, the results of our preliminary measurements agree with those of earlier work in other laboratories. We have obtained two active components with periods of 22 ± 3 sec. and 100 ± 15 sec. respectively. The ratio of their intensities is about 1. However, the relatively considerable number of decay electrons is very remarkable. We have obtained, for example, in the first and second minute, 5·1, 1·8 counts as a mean value from 100 measurements, the background counts being deducted. We can state, therefore, that it is indeed not hopeless to search for nuclear reactions of this kind with such a low voltage. By comparison with a preparation of radium-beryllium with known content of radium, we can say that the artificial activity produced by our process is equivalent to that of the unslowed neutrons of such a preparation containing about 6·8 mgm. of radium element. Of course, that does not mean that the number of the neutrons emitted will be the same in both processes; we cannot yet state anything on this point because of the difference of the velocities of the neutrons in the two cases, and we know nothing about the velocities of our neutrons.

The experiments are being continued and will be completed from this point of view.

A Photo-electric Method for the Measurement of the Optical Constants of Metals

THE optical constants of a metal are measured by allowing a beam of parallel light, plane-polarized at an azimuth of 45°, to fall on the plane polished surface of the metallic specimen, and then analysing the reflected elliptically polarized light. From the constants of the ellipse, and the angle of incidence of the light, the optical constants may be calculated.

The methods hitherto adopted for the analysis of the elliptically polarized light fall into three groups:—(i) photographic methods for the ultra-violet; (ii) visual methods for the visible region; (iii) bolometric methods for the infra-red. Of these the most accurate are the visual methods.

In essentials the present method is similar to the visual methods, but since the eye is replaced by a photo-electric cell, the range of application is extended to include the ultra-violet and infra-red portions o the spectrum. The method in principle is as follows The elliptically polarized light is analysed by transmission through a Soleil-Babinet compensator and a Nicol prism. The photo-electric cell in conjunctio with a Lindemann electrometer becomes the objectiv indicator for the determination of the correct setting of compensator and analyser to produce extinctio of the light.

In practice, for a variety of reasons, complete extinction cannot be obtained. There is always a certain amount of background light (of the order of 0·5 per cent of the maximum illumination). Hence instead of adjusting for zero intensity, one adjusts for minimum intensity. This, however, does not reduce the accuracy of the settings, provided the light source is steady. When the light source is unsteady, as for example in a carbon arc, large irregular fluctuations of the electrometer needle are produced. This effect is eliminated by using a compensating beam of light, derived from the same source, and a second photo-electric cell. The accuracy of the results obtainable compares favourably with the accuracy obtainable by visual methods.

Although not expressly designed for the purpose, the same method may be used for determining optical rotatory power.

Full details will be published elsewhere.

Determination of Vitamin C in the Living Organism

WHILE determining the vitamin C content of urine taken from healthy individuals or patients suffering from various diseases by titration with 2-6 dichlorophenolindophenol, we tried to perform this test in the living organism itself. First we injected small quantities of a 1/1,000 normal sterile solution of the dye into the sole of healthy and scorbutic guinea pigs. We observed that decoloration of the dye takes place much more rapidly in healthy animals than in guinea pigs suffering from scurvy. When methyl blue was injected simultaneously, its colour remained unchanged, which shows that decoloration of dichlorophenolindophenol was not due to resorption but to reduction.

Next we tried to show that this reduction is caused by ascorbic acid, and performed similar experiments on human beings. Patients were kept on a vitamin C deficient diet for 10 days and then 1/400 normal dye solution was injected into the forearm. Using a 1·0 ml. tuberculin syringe, it is not difficult to produce a bubble of about 2 mm. diameter. After observing the time of decoloration, various amounts of ascorbic acid were given intravenously. The colour of the newly injected dye disappeared in a much shorter time than before.

Detailed experiments have shown that the time of decoloration depends on the amount of ascorbic acid present in or administered to the organism. We concluded from our numerous experiments that a decoloration time of about 5 minutes indicates *saturation*, that of more than 10 minutes *deficiency* of vitamin C, while decoloration times of 5–10 minutes show *normal* content of vitamin C of the body.

We believe that this simple reaction may prove useful for many purposes.

Churning for Butter

THE familiar process of churning cream to yield butter has led to two different theories of the mechanism involved. The Fischer-Hooker[1] theory is that churning is due to the reversal of an *O/W* emulsion (cream) to a *W/O* emulsion (butter), a view accepted by Palmer[2]. Rahn[3] believes that churning involves æration or frothing with consequent accumulation of milk proteins adsorbed at the newly-created air/liquid interface.

We accept Rahn's theory and hold that emulsion *inversion* is not concerned; rather is it emulsion *breaking*, due to the preference of the proteins for an air/liquid interface rather than a fat/water interface. The subsequent kneading together of butter granules results in an accidental resemblance to a *W/O* system.

If the milk proteins be restrained from accumulating in the froth (where surface denaturation occurs) churning could progress indefinitely without butter granules forming. We tested this idea by adding very surface-active materials to fresh cream of 50 per cent butterfat content (*p*H 7), so that these materials would undergo preferential adsorption in the froth. Saponin and bile salts have proved excellent anti-churning agents. Thus, 1 in 1,000 of saponin in the aqueous phase, added to cream which normally churned in 60 minutes, totally inhibited butter formation for hours. Its effect was still apparent even when the cream contained 50 per cent of sucrose to load the water phase and assist emulsion breaking; without saponin, such cream churned dramatically in 15 minutes. Egg albumen delayed butter formation until surface denaturation of this colloid allowed the accumulation of the milk proteins at the air/liquid interface.

Colloids which are not particularly surface-active have, as anticipated, no influence on the progress of churning; for example, 1 per cent of gum arabic in the cream.

Our complete results are being prepared for publication elsewhere.

Reactions Caused by 'Activated' Alumina

WE have observed that passage of a chloroform solution of diacetyltoxicarol through alumina activated for chromatographic adsorption causes 'hydrolysis'; in one experiment, 1·1 gm. of pure toxicarol was isolated from 2 gm. of ester. Of the two acetoxy groups attacked, one was derived from a phenolic, the other from an enolic hydroxyl group; both are very readily hydrolysed by alcoholic alkali. This hydrolysis, which is the more remarkable in that it occurred in a non-polar solvent, was traced to the alkalinity of the alumina used. Commercial 'activated' alumina in water reacts alkaline to phenolphthalein and the alkalinity can be titrated with sulphuric acid; the colour returns if the mixture is kept after neutralization; further quantities of acid are consumed after six and again after eighteen hours; thereafter the supernatant solution remains colourless. The following figures are for 5 gm. of (1) Merck's alumina for adsorption, activated according to Brockmann, (2) B.D.H. aluminium oxide for adsorption purposes, (3) B.D.H. aluminium oxide, calcined, and (4) B.D.H. aluminium oxide (calcined) 'AnalaR', shaken in 50 c.c. of distilled water.

	c c of 0 1 N H_2SO_4 consumed				% Alkalinity calc. as NaOH
	At once	After 6 hr.	After 18 hr.	Total	
1	2·0	1·2	0 8	4·1	0 33
2	3·5	1 1	0 6	5 2	0 41
3	0 3	0 1	0·1	0 5	0 04
4	0·2	0 1	0 1	0·4	0·03

The amounts of adsorbed alkali, as shown in the last column, for the 'activated' aluminas are surprisingly high. The low figures for the ordinary aluminas are a satisfactory 'control'.

Hydrolysis of diacetyltoxicarol is prevented by previously washing the alumina with acetic acid or a solution of phenol in a neutral solvent (we are indebted to Prof. Heilbron for suggesting the use of phenol), but the activity of the adsorbent is largely destroyed by acetic acid and to a less, but still considerable, extent by phenol.

Other reactions of rotenone and its derivatives normally associated with the use of alkali in a hydroxylic solvent can also be effected by passage through activated alumina in chloroform or benzene, and we hope to report these experiments in detail elsewhere. Great caution is advisable when adsorbing alkali-labile compounds. It seems probable that the alkalinity of activated alumina may be responsible for some of the abnormal results recorded by other workers, for example, the isomerization of carotene[1], and the partial inactivation of vitamins A[2] and K[3].

Nature of the Linkages in Proteins

THERE is now a considerable amount of agreement that the polypeptides in the protein molecule are held together by cross-linkages[1], but so far crucial experiments, from which the exact nature of these linkages may be deduced, are lacking. The only logical procedure is therefore to consider in turn all possible types of link and to investigate experimentally the deductions to be made from those which pass the qualifying test of being geometrically feasible. Among the links so far proposed are: (*a*) hydrogen bonds[2,3,4], (*b*) cyclol links[4,5,6] and (*c*), as a deduction from (*b*), hydroxyl bonds[4,5].

The hypothesis of hydrogen bonds has recently gained further support from the suggestion, contained in the interesting communication from Dr. Huggins in NATURE of March 25, of synchronized oscillations in hydrogen bridges[7]. The importance of these synchronized oscillations is not confined to proteins but relates to all megamolecules. In connexion with Dr. Huggins's letter, I would direct attention to the diagram given by Jordan Lloyd on p. 267 of her 1932 paper of the structure involving hydrogen bonds associated with . . . HNCOHNCO . . . strings which is now proposed by Dr. Huggins. Further, I may perhaps be permitted to point out that "pictures of this sort" which Dr. Huggins finds "preferable to those proposed by Wrinch", have in fact already been given by Wrinch and Jordan Lloyd[3], and that in any event (as there explained) they are not inconsistent with the cyclol structures which (presumably) Dr. Huggins had in mind. It may well be the case that all three types of link are relevant to the question of the structure of proteins in its various aspects, and possibly others so far unformulated. Thus the prudent course is to seek for support for each and every type of link which is geometrically feasible.

If, however, at this early stage in the history of the protein molecule, it is important to decide between alternatives which are not mutually exclusive, I suggest that it would be of interest to consider how far hydrogen bonds alone can (1) yield structures for protein films and (2) yield structures for the globular proteins which explain the non-random distribution of the molecular weights of proteins established by Svedberg[8] and (3) explain the relation between α- and β-keratin. It appears from a recent series of experiments by Langmuir, Schaefer and Wrinch[9] that the mechanical characteristics of protein films are in good accord with the cyclol hypothesis and its predictions: it is now clear that this hypothesis implies the existence of globular proteins and explains why they fall into discretely arranged molecular weight classes[10]: further, the cyclol link appears to fit elegantly[6] into Astbury's keratin structures. Alternative structures depending upon hydrogen bonds alone would, however, be of great interest.

[10] As explained in a communication to the Editor of NATURE dated March 10, 1937.

Isomerism of Derivatives of Cyclohexane

BOTH 4-methyl*cyclo*hexane-1-carboxy-1-succinic acid and 3-methyl*cyclo*hexane-1-carboxy-1-succinic acid, synthesized by condensation of ethyl bromoacetate with the sodio derivatives of the dicyano esters prepared by Higson and Thorpe's method[1], have been isolated in two forms; there being no indication of isomerism connected with multiplanar forms[2]. This method provides a satisfactory synthesis of the tricarballylic acids derived from cyclic ketones, and the low yield of αα-dimethyltricarballylic acid obtained from acetone[3] can be raised to nearly 30 per cent by suitable modification of the method. The conversion of the tricarballylic derivatives into the corresponding aconitic acids is being investigated.

The Retinal Centre as an Amplifier of Potential Differences

FROM the histological point of view the retina may be regarded as a nervous centre, a piece of the brain, projected on the surface of the body. With other centres it shares the property of responding to stimulation with slow potential changes. Thus, when light falls on the eye, the corneal electrode becomes positive with respect to an electrode behind the eye (vertebrate eye with inverted retina). This change coincides with the appearance of impulses in the optic nerve. Negativity of the corneal electrode coincides with inhibition of the discharge in the nerve[1]. Below we are only interested in the initial positive phase of the retinal response, called the *b*-wave (see Fig. 1), known to be a measure of excitation.

Assume that at regular intervals a *b*-wave is elicited by a constant stimulus, and that on top of this *b*-wave is thrown another stimulus. The latter, the 'test light', exceeds the former 'adapting light' in strength and therefore succeeds in eliciting a second small *b*-wave on the falling part of the *b*-wave, caused by the adapting light (Fig. 1).

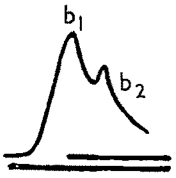

Fig. 1.

RETINAL RESPONSE; b_1 DUE TO 'ADAPTING LIGHT', b_2 TO 'TEST LIGHT'.

As 'test lights' are now chosen two stimuli which taken by themselves differ in size by about 8 per cent. They are then in turn superimposed upon the *b*-wave set up by the regularly recurring 'adapting light'. Do the small *b*-waves to which the test lights now give rise still differ by 8 per cent? An experimental answer is easily obtained. The superimposed *b*-waves are found to differ by, say, 34 per cent, to quote figures actually obtained in an individual experiment. Thus the difference between the test lights has been amplified owing to the fact that the retina has been charged by an earlier stimulus. This 'amplifier principle' has been studied in several ways, mostly with fairly strong stimuli, differently introduced with respect to the various phases of the electro-retinogram.

The fact that amplification may occur in a centre is obviously of general interest for all those who in different fields are trying to understand the working of the central nervous system in terms of simple principles. It illustrates a way of attacking the complicated functions involving differentiation. From the point of view of vision, the amplifier principle gives a clue to an understanding of processes of discrimination such as 'visual acuity', 'brightness discrimination', etc., all of which within limits are favoured by bright stimuli and an illuminated background. Together with many other recent results obtained with the electro-retinogram, it points to the significance as well as to the necessity of considering small eye-movements in connexion with visual discrimination.

Perception of Weight and Elasticity

IN experiments on the perception of elasticity, we have found that individuals equate a pull on an expanding elastic spring with a much *lighter* lifted weight impression. Lifting a weight of 2·50 kilograms (for which the psycho-physical limen is of the order 0·10 kilogram) was matched by one person with a pull as large as 6·50 kilograms (probable error 0·20 kilogram). On the average, from results with some fifty persons, a lift of 2·50 kilograms is matched for weight with a pull on a spring of 4·00 kilograms approximately (probable error 0·25 kilogram). The under-estimation of the spring or elastic pull in terms of weight perception is of the same order irrespective of whether the subject begins with a zero pull in the spring, gradually increasing this until a match with the lifted weight impression is obtained, or whether he begins with a pull of the order 8·00 kilograms, gradually decreasing this until a match is obtained. The effects are just as marked, also, when a pull is used as standard for comparison with a series of lifted weights.

This difference between the effects of a pull and a lift points to phenomenalogical differences in the impressions of weight and elasticity, and has interesting practical bearings on the general psychology of physical training. An account of our experiments will be published, it is hoped, in the *British Journal of Psychology*.

Scientific Research in Spain

GRATIFYING evidence that scientific investigation and literary research are by no means at a standstill in Spain has been received by the Society for the Protection of Science and Learning, the permanent successor to the Academic Assistance Council.

With their letter dated February 24, 1937, Prof. Manuel Marquez Rodriguez (dean of the Faculty of Medicine in Madrid), Prof. P. Carrasco (dean of the Faculty of Science in Madrid) and Dr. T. Navarro Tomas (director of the National Library)—all well-known authorities—have sent two copies of recent numbers of the *Anales de Fisica y Quimica*, a copy of *Revista de Filologia Espanola* and a copy of the *Anuario del Observatorio de Madrid* for 1937, which last has recently been referred to in NATURE (April 10, p. 624).

The continuation of such original work as is described in the above publications—and others are to follow—has been made possible by the founding by the Ministry of Education of the *Casa de la Cultura* of Valencia, the objects of which appear to be similar to those of this Society. The *Casa de la*

Cultura houses members of various professions, from whom, the Society is informed, the Ministry has not asked for any declaration or guarantee of a political character. Further, the Ministry has not compelled those, who for special reasons, prefer to remain in Madrid, or to live in other places, to go to Valencia. While teaching has had to be interrupted in the universities, the Ministry has not ceased to pay salaries to professors and others who have remained in the provinces under the authority of the Government. The Ministry is also trying to apportion help to Spanish professors and scholars abroad who have not rebelled against the Government.

Complete detachment from prevailing social and political conditions is usually impossible for the scientific and literary worker and, during the last few years, the work of many well-known scientists and scholars has been adversely affected by conditions against which they have been powerless. A census of outstanding advances in knowledge achieved during this period by those so adversely affected and helped by their colleagues and sympathisers would provide a unique and important historical record.

Points from Foregoing Letters

PHOTOGRAPHIC records of electrical disturbances occurring during a thundercloud discharge, obtained with a cathode ray oscillograph, are submitted by Dr. F W. Chapman. By means of a device in which the photographic film moves at right angles to the time-base deflection, electrical pulses only a few micro-seconds apart can be resolved. The records show a volley of discharges, presumably to be identified with the 'brush' discharge often observed in an active cloud as a prolonged flicker or flow, followed after a brief quiescent interval by the main lightning discharge. The volley radiates a long series of electromagnetic waves producing interference in radio receivers, while the main discharge consists of series of steps separated by 30-100 micro-seconds, their quasi-period corresponding to a wave-length of 15–30 km.

It is known that the beryllium nucleus, irradiated by γ-rays, emits neutrons, but it has not been decided by physical methods whether the nucleus is thereby transformed into an isotope of beryllium of mass eight, or into two helium atoms. By a micro-chemical method, Prof. F. A. Paneth and Dr. E. Gluckauf have detected, in irradiated beryllium, helium in such quantity that the helium-forming process seems to be the main, if not the only, reaction.

A method for the estimation of enzyme activity by following the change in the density of the medium is described by Dr K. Linderstrøm-Lang. Small drops of the enzymatic reaction mixture, at different stages, are introduced into a vertical glass tube containing kerosene and bromobenzene in suitable proportions to give a practically constant specific gravity gradient, and their density is determined by comparison with similar droplets of known composition which float at given levels, according to their density. Curves are shown giving the change in specific gravity with time and the amount of amino-nitrogen liberated in the case of mixtures containing *dl*-alanylglycine and peptidase.

What appears to be a complete cycle of development of malaria parasites has been observed by Prof K. B. Williamson and M. Zain in controlled experiments with *Culex bitæniorhynchus*, a mosquito hitherto not considered a malaria carrier. The authors suggest that its ability to carry the malaria germs may be related to the fact that it breeds in pure, uncontaminated water.

In East Greenland and northern Spitsbergen the littoral mite *Molgus littoralis* extends its range beyond the shore, probably due to the non-occurrence of big competing mites. In southern Spitsbergen it seems to develop more than one generation in the year. In East Greenland, according to H. Madsen, only one generation is developed, the species wintering in the egg.

In experiments on the semicircular canals of the pike, Dr. O. Lowenstein shows that the sense organ in the ampulla of the horizontal canal has a tonic function, and that a single horizontal canal is capable of evoking muscular responses to both clockwise and anticlockwise rotation of the fish in a horizontal plane.

In an investigation on the lower limit of voltages with which artificial radioactivity can be produced, E. Bertl, Prof. R. Furth, F. Obořil and Dr. K. Sitte have obtained two active components, of period 22 and 100 seconds, by irradiating silver with slow neutrons produced by the action of slow deuterons (positively charged heavy hydrogen nuclei) upon beryllium-coated mica.

The addition of saponin (1 in 1,000) to cream, which usually churns in 60 minutes, delays the formation of butter for several hours, according to Dr. W. Clayton and J. F. Morse. Similar inhibition was observed with egg albumin. The authors accept Rahn's theory that during churning the milk proteins around the fat particles are removed by the aeration and frothing, and this leads to the coalescence of the fat globules.

Drs. R. S. Cahn and R F. Phipers report that commercial 'activated' aluminas contain relatively large amounts of adsorbed alkali and can bring about, in neutral solvents, reactions normally associated with alkaline reagents in hydroxylic solvents. They suggest that the alkalinity may be responsible for abnormal results recorded by other workers.

Commenting on Dr. Huggins's communication on "Synchronized Oscillations in Hydrogen Bridges", Dr. D. M. Wrinch points out that similar speculations have been put forward by Wrinch and Jordan. The author claims that the mechanical characteristics of protein films are in good agreement with her 'cyclol' hypothesis and its predictions.

An experiment is described by Prof. R. Granit showing that the difference in the initial positive electrical response from two test stimuli applied to a retina is increased (from 8 per cent to 34 per cent) when the retina is 'charged' by an earlier stimulus. This may explain why visual acuity, brightness discrimination, etc., are favoured by bright stimuli and an illuminated background.

Research Items

Pithecanthropus—Man or Gibbon ?

THE arguments put forward by Dr. E. Dubois in support of his view that *Pithecanthropus erectus* is to be regarded not as a man, but as a genus allied to the gibbon (see NATURE, Feb. 13, p. 291) have been examined and met by Prof. W. E. Le Gros Clark (*Man*, April 1937). The evidence of the volume of the endocranial cast provides no ground for inferring kinship between two animals because their cerebral development is different Dubois' startling conception that the brain in its phylogenetic development grows discontinuously by doubling its size at each stage rests on quite inadequate observation. The endocranial capacity of *Pithecanthropus* may be assumed to be somewhere between 900 c.c. and 1000 c.c., and of *Sinanthropus* I at 915 c c. Yet Dubois, while insisting that *Pithecanthropus* is gibbon, accepts Peking man as human. *Pithecanthropus* even comes within the range of modern man, of whom examples have been noted with a cranial capacity of about 833 c.c. A number of features in the endocranial cast of *Pithecanthropus* indicate a human status. Such are the convolutional pattern of the frontal lobes, which are more complex than in the apes, and the extremely simple fissuration of the brain, while the 'association areas' must have been incomparably more extensive than in the anthropomorphous apes, and the expansion of these areas can only be related to the development of mental attainments distinctive of the Hominidæ. The characters of the femur, which Dubois takes to indicate the gibbon status of *Pithecanthropus*, are open to serious question. Not only does the palæontological evidence not support his prejudice against the view that the Trinil femur is human because this implies that the frame of man reached its perfection for pedal progression long before his brain attained its present complex structure, but also the arboreal habits believed to be related to other characters of the femur are not proved conclusively. The evidence of the lower jaw fragment from Kedung Brubus is so questionable that it scarcely deserves serious consideration.

Arctic Birds in New Zealand

A SHORT but extremely interesting list of arctic birds which spend the northern winter in New Zealand has been compiled by R. A. Falla, covering fresh records since Oliver's paper in 1930 (*Rec. Auckland Inst. Mus.*, 2, 1 ; 1936). They include fourteen pecies, of which the two most common forms in New Zealand are bar-tailed godwits (*Limosa lapponica aneri*) and knots (*Calidris canutus*). Others are two pecies of skuas, turnstones, Asiatic golden plover, hree species of sandpiper, Asiatic whimbrel, two pecies of phalarope. Considering the small number of expert observers in New Zealand and the wide xpanses which must go unnoticed, the list promises that further work is likely to add many names to this wandering fauna As a rule, the migrants arrive bout October in winter plumage, and set out on the return journey in April, when the adults have completed a pre-nuptial moult. Mr. Falla considers that birds of the year, which have not completed their post-juvenal moult in April, do not migrate, but spend the southern winter in New Zealand. The northern movement of the adults in April, however, bears upon Prof. Rowan's suggestion that increasing daylight is the stimulus which sets the migratory movement in motion, for on the contrary these New Zealand wintering birds undergo the physiological changes associated with migration, and commence migration while the days are shortening.

Studies of Species of *Silene*

E. M. MARSDEN-JONES and W. B. Turrill have continued their investigations on the genetics, life-histories and ecology of *Silene vulgaris* (*S. Cucubalus*) and *S. maritima* in the seventeenth paper of the series "Researches on Silene maritima and S. vulgaris" (*Bull. Misc. Inform., Kew*, 45–53, 1937). In this paper, the genetical relationships of a Welsh mountain plant are discussed on the basis of controlled selfings and crossing with typical *S. maritima* and *S. vulgaris*. The Welsh plant is classified taxonomically as a variety of *S. maritima*, but shows a number of aberrant characters which suggest either previous contamination with *S. vulgaris* or the retention of more ancient phenotypic character combinations than now usually found in coastal populations. Analyses are given of the genetical behaviour of a large number of crosses, and some are compared with results obtained in earlier researches. The importance of this series of papers is that a very full knowledge of two species of plants is being obtained from many points of view : cytological, ecological, genetical, phyto-geographical and taxonomic. When the work that has been planned is completed—and it is well in hand—the real make-up and history of these two species will probably be better known than for any other species of wild plants.

New Species of Algæ

ON the Templeton Crocker Expedition of the California Academy of Sciences 1932, a number of algæ were collected from thirty-two stations, principally among the Galapagos Islands. W. A. Setchell and N. L. Gardner of the University of California are working out this collection. They have published a preliminary account of the new species, varieties and combinations that have been identified up to the present (*Proc. California Acad. Sci.*, 22 ; 1937). The new species already amount to 45 (18 Myxophyceæ, 1 Chlorophyceæ, 3 Melanophyceæ and 23 Rhodophyceæ). Collections along the coast of Lower California are also interesting in extending farther south the known distribution of many Californian species. The authors hope to publish the full account shortly.

Variation of Wind with Height

A DISCUSSION of the variation of wind with height at Wadi Halfa (Sudan), by J. Durward, is the subject of Professional Note No. 72 of the Meteorological Office, Air Ministry. The direct observation of upper winds by pilot balloons is being extended into many parts of the world where the average values of those winds were formerly deduced from cloud movement, or from maps of computed pressure distribution at different heights deduced from observed surface pressure and assumed upper air temperature, and it is interesting to see to what extent observation supports theory. Wadi Halfa lies just inside the tropics, and is several hundred miles from the nearest point on the Red Sea. Were it not for its continental position, the predominance of winds from between north and north-east noted up to a height of about 4,000 feet might be described as appropriate for a place in the north-easterly trade-wind belt of the northern hemisphere, but these winds are better classified with the etesian winds of the Mediterranean and Egypt. At Wadi Halfa the wind from December to February generally backs with increasing height above 4,000 feet and normally blows from about north-west between 10,000 feet and 13,000 feet. In Shaw's "Manual of Meteorology" (2, p. 259 of 1928 edn.) is shown a map of normal pressure at a height of 4,000 metres (13,000 feet) due to Teisserenc de Bort, and on it the isobars run from about west-south-west to east-north-east. If the wind follows the isobars at that level there is therefore an apparent discrepancy of nearly 70° between observation and theory. Observation in this case covers one year only, but that is held to be a long enough period in which to obtain normal winds at Wadi Halfa, where the constancy of the pressure gradient throughout the year is remarkable and the wind is in consequence remarkably steady.

New Method in Geometrical Optics

In a series of memoirs, starting in 1890, A. Gullstrand has made a deep investigation into the properties of optical systems, and in particular has put forward the thesis that no optical instrument can give a point-to-point correspondence between two surfaces, but that there are, on each surface of the object space, two systems of lines that can be represented point by point in the image space. Unfortunately, Gullstrand's methods are very complicated. Boegehold and Herzberger managed to simplify them in a particular case, that of his "fundamental law". Now C. W. Oseen ("Une méthode nouvelle de l'optique géométrique", *Kungl. Svenska Vetenskapsakademiens Handlingar*, Tredje Serien, 15, No. 6; 1936) has given a general method, based upon contact transformations and their invariants. Because the calculations have a character independent of the choice of co-ordinates, all the terms introduced have a geometrical or optical significance. This new method gives a large part of Gullstrand's results, in some cases making them almost obvious, and also gives other results not previously obtained. Oseen comes to the conclusion that Gullstrand's theory of representable lines is not general, and that there really is an optical image corresponding to any surface of the object space. He attributes Gullstrand's failure to reach this conclusion to the illegitimate assumption that the ray always cuts the surface considered at an angle different from zero.

Diameter of Lightning Discharge

Theories of the processes taking place in a lightning discharge channel involve the size of the channel, but the experimental evidence on this point has been confused. B. F. J. Schonland (*Phil. Mag.*, March) has been able to examine a photograph of a lightning flash taken at short range (about 250 metres) which enabled him to make a direct estimate of the diameter of a discharge. Successive strokes of the flash were separated by the wind, and may readily be distinguished on the photograph—there were about ten strokes separated by intervals of about 0·05 sec., so that the whole flash lasted about ½ sec. The negative was sufficiently free from over-exposure and halation to allow a determination of the discharge diameter, the distance of the flash from the camera being known. The values found ranged from 23 cm. for the heavy first strokes to 11 cm. for weak branch strokes. There is a discussion on the question whether these figures represent the actual diameter of the electrical core of the discharge.

Further Atomic Transmutations by Means of γ-Rays

The production of radioactive isotopes by bombarding elements with an intense beam of γ-rays from lithium recently reported in these columns (Nature, 139, 555; 1937) has been further extended (W. Bothe and W. Gentner, *Naturwiss.*, 25, 126, 191; 1937). The isotope of bromine ^{78}Br has been obtained, with a half-life of 3·5 min. Silver gives ^{106}Ag with a half-life of 24 min. Zinc gives a nucleus with a half-life period of 38 min., probably to be identified with ^{63}Zn. Gallium gives two isotopes, ^{70}Ga and ^{68}Ga, with half-life periods of 20 min. and 1 hr., respectively Tantalum gives ^{180}Ta with a half-life of 14 min. In some cases radioactive isotopes were produced which have not yet been identified. Thus molybdenum gives a nucleus of half-life 17 min., and antimony gives one with a half-life of 13 min., which is probably ^{120}Sb. Indium gives either ^{112}In or ^{114}In with a half-life of 1 min., and tellurium either ^{127}Te or ^{129}Te with a half-life of 1 hr.

Lead-Uranium-Thorium Ratio in Uraninite

Recent investigations show that the composition of a single crystal of uraninite may not be uniform throughout the crystal. C. M. Alter and L. A. Yuill (*J. Amer. Chem. Soc.*, 59, 390; 1937) have now examined a single well-developed crystal of uraninite from the Wilberforce locality weighing approximately 42 gm., which was divided into three parts, outer middle and core, by filing each face down an equa amount, the particles of steel being removed magnetically. Determinations of the lead-uranium-thorium ratio of the sections confirmed the variation o composition disclosed in previous work, in which the sections were removed by solution in acid. The ratio Pb/(U + 0·36Th) was 0·1668, 0·1678 and 0·1864 fo the outside, middle and core, respectively. Th higher ratio in the core is unusual, and the ratio are different from those found previously with other crystals. The discrepancy in age using the data for the whole crystal and those for the core amounts to approximately eighty million years, while the discrepancy between the ages calculated for the whole crystal and the outside portion is about forty million years. The age of the mineral, as calculated by formula given in the paper, is 1,100-1,200 millio years, so that the relative error is not so serious although the results emphasize the need for carefu selection of material in order to obtain reliable dat for age calculations. Erroneous results may b obtained by the analysis of a single crystal if th whole crystal is ground and analysed.

Distribution and Characteristics of Early Man

IN celebration of the one hundred and twenty-fifth anniversary of the founding of the Academy of Natural Sciences of Philadelphia, an international symposium on early man was held at the Academy on March 17–20, when a number of representative archæologists from all parts of the world were present. In addition to the introductory address by Dr. John C. Merriam, president of the Carnegie Institution of Washington, and chairman of the committee for the symposium, thirty-two communications were presented, and four round-table discussions on problems of chronology and distribution took place. Broadly, the programme was arranged so that the communications presented on each day dealt with the problems of a continental area: on March 17 communications dealing with Europe or bearing on general problems of correlation with European cultures, on March 18 communications concerned with America, on March 19 matters relating to Asai and the Pacific and general problems arising out of the evidence therefrom, and on the closing day a small group of miscellaneous communications. The proceedings closed with a review of the problem of early man, based on the communications presented at the symposium, by Dr. G. Grant McCurdy.

In the following report mention is made only of the communications of wider general interest.

The proceedings on March 17, following on the introductory address, opened with a communication by Dr. G. H. R. von Koenigswald reviewing man's geological record in Java, and this was followed by a survey of the palæolithic industries of China by Mr. W. C. Pei, which suggested some triking correlations with the palæolithic industries of Europe. The most ancient artefacts of China identified by Abbé Breuil are the Nihowan, a piece of worked stone and some pieces of worked bone, n geological age Upper Pliocene and equivalent to the Villafranchian of Europe. Locality 13 industry, represented by a chert implement of undoubted uman origin, corresponds to the Abbevillian of France and geologically is attributed to an early phase of Lower Pleistocene. Of the four main industries of China, Sinanthropus, which begins the rue industry of China, is also attributed to the Abbevillian and the Lower Pleistocene; the newly iscovered and as yet little studied Locality 15 ndustry of Choukoutien, of the early Middle Pleisocene, corresponds to the Late Lower Palæolithic of Europe; the Ordos industry, contemporary with art of the Chinese loess, belongs to the late Middle Pleistocene; and the Choukoutien Upper Cave ndustry, which is the Upper Palæolithic of China, orresponds to Aurignacian, Solutrean and Magalenian.

Two communications came from Palestine. Miss Dorothy Garrod dealt with "The Near East as a ateway of Prehistoric Human Migrations" and Sir rthur Keith and Mr. Th. McCown, in a joint comunication read by the latter, reported on the early uman skeletal remains from Palestinian caves on ount Carmel. It was pointed out that the human remains from the Levallois-Mousterian layers of hese caves not only provide new additions to the onsiderable list of fossil specimens of man from the middle part of the Stone Age, but they also provide a new perspective concerning Neanderthal man, present a new type of humanity, which is the probable stock ancestral to the inhabitants of Europe in late Palæolithic times, and place in a new orientation the central problem of the evolution of the modern races of man.

The stratigraphic culture sequence in the three Wady Mughara caves overlaps in such a manner that the record carries us from the Acheulean, through the Levallois-Mousterian, to the Aurignacian and culminates in the Natufian, a new epi-palæolithic culture. The human inhabitants of the caves are represented from the Levallois-Mousterian and the Natufian periods.

Three and a half years intensive work on the bones of the Mousterian peoples of Mugharet es-Skhul and el-Tabun has led finally to the conclusion that we here have two distinct types of man, both living in Palestine at about the same time, and before the marked change in the character of the Pleistocene fauna and in the climate which are to be related with the period of the last glaciation in Europe. Mount Carmel man is certainly pre-Wurmian.

The first type is represented by a young adult woman of small stature (1520 mm.) from el-Tabun. The skull is small and low with a heavy frontal torus, the mandible is chinless and the face prognathous. The pelvis, especially the pubic parts, exhibits primitive anthropoid features not seen heretofore in any human race. This is a type similar to, but not identical with, the Western European Neanderthalians; at the same time it bears an unmistakable relationship to the Skhul people.

The other type of Mount Carmel man comes from the Mugharet es-Skhul. The material consists of two tall adult males, 1738 mm. and 1780 mm., that is, nearly or quite six feet. Their lower limb bones in measurement are closest to those of the tall Cromagnon males. Other parts of the skeleton corroborate with varying emphasis. The large well-vaulted skulls exhibit frontal tori with greater or lesser degrees of development, the large palate protrudes, and is completed by a mandible with a clearly defined chin and a modern internal conformation to the symphysis. The teeth do not show the taurodont condition of Neanderthal man, nor indeed do those of the Tabun type. The teeth of a well-preserved child, as well as of other young individuals, show unmistakable traces of a primate ancestry.

In all there are the remains of ten individuals on which conclusions are based. One of the most important points to emerge is their great variability. Their anatomical characters fall into three categories. In the first group, which is small, are the characters like those of the Western European Neanderthals; in the second, slightly larger, are intermediate characters between those of Neanderthal and of Neanthropic man; and the third, which contains by far the greater number, comprises the characters similar to those found in the Upper Palæolithic inhabitants of Europe, leading to the conclusion that there is a genetic relation between the ancient Palestinians and the Cromagnons. In reviewing the evidence as a whole, it may be said that the Skhul people are at least contemporaries, and possibly considerably earlier than the men of La Chapelle, La Ferrassie, of Spy and Neanderthal. They bear the imprint of characters inherited from a type ancestral both to themselves and to the European Neanderthalians. These new fossils show conclusively that the Western European Neanderthals were not ancestral to the modern races of mankind; they clearly demonstrate for the first time that evolution was well advanced in the different groups of *Homo sapiens* in the middle Pleistocene. "Chronologically the Skhul people are too recent and physically they are too distinctive to serve as a form ancestral to *Homo sapiens* in the widest sense of that term. They do provide us with a variety of man who may be considered as the prototype of the earliest modern Europeans".

More immediately based upon the European evidence relating to early man was a communication by Prof. A. W. Brøgger, dealing with the extension in distribution of late Palæolithic man to the extreme north in northernmost Norway. The remainder of the first session was devoted to the application of recent developments in method in European archæology to American conditions.

In the American session on March 18, the number of communications offered was considerable, opening with Dr. A. Hrdlička's discussion of early man in America in the light of the skeletal evidence. Chronological problems were discussed by Mr. Herbert J. Spinden, and Dr. Ernst Antevs dealt with climate and early man. The Folsom problem received attention from Dr. Frank H Roberts and others, and several communications dealt with the question of the evidence of geology and palæontology. Mr. Edwin H. Colbert on the pleistocene mammals of America and their relation to Eurasian forms argued for a considerable interchange in pliocene and pleistocene times, with eventually a much later survival in America of certain typical pleistocene forms, such as mammoth, camel, horse, extinct bison and sloths, into recent times.

On March 19 communications dealing with the prehistory of Asia were taken, opening with a contribution by P. Teilhard de Chardin dealing with the Late Cenozoic relations of North China, Malaysia and Central Europe, in which the entry of *Sinanthropus* into China, probably from the south, was shown to follow an eastern Asiatic uplift which was responsible for changes in earth surface, climate and fauna, and a review of the traces of fossil man in Mongolia by Prof. C. Charles P. Berkey, of Columbia University.

A communication by Prof. V. Gordon Childe, reviewing the evidence relating to the North Eurasian Forest Culture in the Mesolithic and Neolithic phases, drew an interesting parallel between the conditions, which had to be faced by the hunting peoples of northern Europe from Britain to the Urals at about 7000 B.C. with those which had confronted the aboriginals of north America in comparable zones. This forest culture, the Maglemosean, had adapted itself to specialized forms of hunting and fishing, using dog-sleighs (runners found in boreal peat in Finland are the oldest dated evidence for any vehicle for the use of man) conical arrow-heads for killing fur animals, and ice-picks. This East Maglemosean equipment is found right across Central Russia, where, however, it seems to be post-boreal and may mark local survivals of a boreal extension of the Maglemosean. With the more favourable climatic conditions around Denmark of the Littorina transgression, the Ertebølle shell-mound culture is to be regarded as an adaptation of the Maglemose to new conditions, its pottery being due to the foreign influences, which afterwards produced the Nordic neolithic cultures of north Germany, Denmark and southern Sweden. East of the Baltic the environmental change was insignificant, and the old economy persisted. Later in Finland the hunting and fishing economy was transformed by battle-axe folk, who introduced agriculture and stock breeding. The same transformation was effected in central Russia by the Fatyanovo battle-axe folk, yet there pit-comb pottery survived into the Iron Age after 800 B.C. In the Urals late sub-boreal peats have yielded pottery like the Finnish and Central Russian neolithic wares and the aforementioned bone-work of Maglemosean character. Thanks to such survivals, the makers of pit-comb pottery and so also their Maglemosean ancestors can be linked up with the historical Finno-Ugrian peoples.

A more remote problem was considered by Milo S. Hellman and Prof. W. K. Gregory, in examining the evidence of dentition in its bearing on the origin of man in the light of the new anthropoid ape material obtained in the Siwalik Hills, North India, by Dr. de Terra and Mr. G. E. Lewis. The communication was limited to two problems, the origin of the *Dryopithecus* pattern of the lower molar crowns and the known limits of variation of that pattern in fossil and recent anthropoids, and its transformation into the cruciate or four-cusped pattern in the more advanced lower molars of man. Among the conclusions put forward may be mentioned that while the *Dryopithecus* pattern is subject to extreme variation in regard to proportions, it is constant in the fundamental arrangement of the five principal cusps and the several grooves at their base; that of all the variations of the pattern, that of the first lower molar of *Australopithecus* is the closest to the human modification of the *Dryopithecus* pattern, though the tooth itself is far too broad to give rise to that of man; that of the known human first lower molars, that of the palæoanthropic division of man, especially of the Ehringsdorf child and *Sinanthropus*, are the least modified away from the *Dryopithecus* pattern; and finally, contrary to most authors, the opinion is expressed that the older palæoanthropines are at least structurally ancestral on one hand to *Homo neanderthalensis* and on the other to *Homo sapiens*.

In this connexion much interest is attached to certain conclusions at which Dr. H. de Terra has arrived as a result of his investigations in the Siwalik Hills. He states that there is evidence to show that the late tertiary mammals of India migrated to south-east Asia, guided by a shifting of the tropica belt from north to south. It was suggested that such migration should be considered as a major factor in human evolution so far as Asia is concerned. The stone age records of early man in India indicate great expansion of the old palæolithic races from southern India to the Siwalik Hills in the middl pleistocene, shortly after the Himalayan glaciers had retreated from their second major advance. Toward the close of the Ice Age, another group of stone manufacturing people invaded the lower Indus valley settling in a region which recent investigation shows to have also an advanced civilization 5,000 years old Hence the Indus valley shares with other larg drainage areas a long tradition of human pre-history

The Biological Station at Barents Sea

IT will interest British biologists and especially fishery research workers to learn that a big new biological station is being built by the Academy of Sciences of the U.S.S.R. at Murmansk on the Barents Sea. The new biological station is intended for extensive research in morphology, anatomy, embryology, physiology, biochemistry and ecology of sea organisms.

Owing to the penetration of the warm waters of the Atlantic into the Barents Sea, the fauna of the latter is extremely rich and diverse. Of importance is the fact that at Dalnye-Zelenets Bay the water is transparent to a depth of 10 metres, and that large stretches of the sea bottom are visible from the surface. The scientific workers at the station will make a detailed study of the problems of evolutionary physiology, embryology and the relationship of the fauna with changed hydrological conditions effected by the Gulf Stream.

The Murmansk biological station will supply biological material to the various research institutes and higher educational institutions of the U.S.S.R. Superintending the building of the station is a special commission consisting of S. A. Zernov (director of the station), L. A. Orbeli, V. I. Vernadsky and N. M. Knipovich, Prof. K. M. Deryugin of the University of Leningrad, Prof. L. N. Fedorov, director of the All Union Institute of Experimental Medicine, and Prof. E. M. Kreps.

The cost of building the Murmansk Station is estimated at 3½ million roubles, excluding equipment. A scientific library, the zoological, botanical, microbiological and hydrochemical laboratories and the libraries of other departments will be housed in the main building of the station. An aquarium designed for scientific work will be installed on the first floor of this building while several other aquaria, open to the public, will be erected in the basement of the building. Premises containing students' laboratories will be situated near the central building, and will also be equipped with large aquaria. Special interest is attached to an open-air concrete reservoir intended to accommodate large sea animals including seals.

The spawn of crabs will be brought from the Far East for acclimitization and breeding in the Barents Sea. A special vessel, 30 metres long, built for scientific work in the open sea will maintain uninterrupted communications between the station and the city of Murmansk.

At the beginning of this year, the Academy of Sciences of the U.S.S.R. commenced extensive work in the Dalnye-Zelenets Bay, east of the Kola Bay (Teriberka district, situated in the Northern Province) for the construction of this biological station, which will be the finest in the Soviet Union. The Soviet architect N. V. Ryumin and his assistants have designed all the buildings.

Irradiation of Plants with Neon Light

AFTER years of experiments in Holland and elsewhere, an appreciable measure of success has recently been achieved in promoting the development of plants by irradiation with artificial light. J. W. M. Roodenburg and G. Zecher, in a paper in *Philips Technical Review* (Eindhoven) of July last describe recent technical developments, and show that it is now possible for the market gardener and the amateur horticulturist to employ irradiation on a practical scale.

The growth of plants is naturally intimately connected with their photosynthesis. As photosynthesis is most active in red light, it is necessary to use red rays. Twenty years ago neon light was suggested, but this light is not so easy to manipulate as glow lamp light, so further experiments were made with glow lamps. These showed that although the development of leaves was promoted, the general quality of the plants suffered, as the stems and stalks grew too 'leggy'. Experiments have now shown that provided the proper 'dosage' is given, neon light is exceptionally suitable for plant irradiation. The stems become thicker, the roots are stronger and frequently he formation of blooms and fruit is much promoted.

When neon lights were introduced for the irradiaion of plants, they had already been employed for several years as luminous advertisements. For these purposes long glass tubes are used, into the ends of which two iron electrodes are fused. The tubes contain a neon filling at a pressure of approximately 10 mm. They are run at a pressure of 3,000 volts and emit a comparatively small luminous flux per metre of tube-length. For use in damp forcing houses for the irradiation of plants, these tubes would be objectionable owing to the risk of shock; moreover, their low brightness makes it difficult to obtain the best illumination. To get a satisfactory illumination, it was necessary to reduce the pressure to 1 mm. or less. But at this pressure the iron electrodes disintegrated rapidly, so that the life of a tube was only a few hours. A solution was obtained by using hot cathodes similar to those used in gas-discharge tubes for highway lighting. This enables the tubes to be run at low pressures.

The hot cathode tubes are connected directly to 220 volts mains supply, through a series-connected 'choke' coil. A simple device is employed for starting up the tube, since the running voltage is too low to initiate the first electric discharge through the low-pressure neon gas. During the burning of the lamp, the cathode suffers practically no disintegration and the light output remains uniform. After 2,000 hours the cathode begins to be atomized and a black deposit forms on the glass walls. The tube should then be replaced. The tubes are short and mounted in reflectors which considerably increase the efficiency of the irradiation.

Photographs are given which show the effects produced by subjecting flowering plants and strawberry beds to irradiation for periods up to three months at eight hours per night in mid-winter. Compared with plants which have not been treated in this way, the forcing effect is very pronounced.

Power and Light for North Wales

AN interesting article on power and light in North Wales by Brig.-General R. F. Legge, manager of the British Power and Light Corporation, Ltd., appeared in the December issue of *Trade and Engineering*, a monthly review of industrial progress, issued by *The Times*. A subsidiary of this company called the North Wales Power Co., which generates all its electricity from water-power, supplies the north of Wales. The area over which the North Wales Power Company operates covers more than 4,000 square miles. The supply is practically unlimited and the price compares favourably with most other industrial areas in Great Britain.

The full exploitation of this area and to a great extent the well-being of its inhabitants depend largely on sound electrical development. Not only has the North Wales Power Company its own water resources, drawn from its lakes in the Snowdonia mountain ranges, on which it has spent several millions in recent years, but also its transmission system has been linked with that of the Central Electricity Board at Crewe. Hence although at present the hydro-electric system is capable of meeting continuous demands, the whole supply is safeguarded by this link with the national Grid and its controlled steam stations. By agreement with the Central Electricity Board, the output of two of the hydro-electric generating stations of the North Wales Co. is controlled and purchased by the British Power and Light Corporation, from which the North Wales Co. repurchases its requirements. In this way the stations are used by the North Wales Co. for peak load operation and supplement the Board's system by meeting the fluctuating demand at various times of the day.

There are more than 1,000 miles of high-tension distribution lines and 300 miles of low-tension, excluding the systems of eighteen local authorities which are supplied in bulk. The North Wales Power Co. itself distributes to some 300 points within the area, affording supplies to more than 150 townships, to rural villages and to independent farms.

The principal industries in North Wales are the quarrying of slate, granite and limestone, the mining of coal, lead and gold, the manufacture of bricks and tiles, wool textiles, artificial silk and chemicals, and agriculture. According to the annual report of the Secretary of Mines, in 1935 the production of slate in Great Britain was the highest for more than twenty years, and the best slate comes from North Wales. The aggregate power required for working the granite and slate quarries is 20,000 h.p. The L.M.S. Railway at Crewe has a connected load of approximately 16,000 h.p. Extensive developments have taken place in milk food production factories. The local farmers in distant rural districts are availing themselves of the power companies' supply for milking and other farm work. In 1914, the Marconi Telegraph Co. erected at Caernarvon the first long-distance transmitting station to be built in Great Britain. It is still in operation, the North Wales Power Co. supplying it with the necessary current.

The diversity of the loads supplied to the various industries is very beneficial. This is seen by the load factor being about 0·56. During the last three years, purchases per annum have increased from 35 to 106 million units.

University Events

Birmingham.—Mr. A. E. Hills, the donor of the new chemistry block, has made a further benefaction of £25,000, to be used for the provision of post-graduate scholarships open to all students of the University, in any faculty, who have taken a bachelor's degree and shown themselves qualified for post-graduate work. The minimum value of a scholarship is to be £150, but the Council may at its discretion increase the sum. The maximum period of tenure is two years, and the scholarships may be used for study in Leeds or any other place approved by the Council of the University. They will be known as the A. E. Hills post-graduate scholarships.

Dr. R. Peierls, assistant-in-research at the Royal Society Mond Laboratory, Cambridge, has been appointed to the newly instituted chair of applied mathematics as from October 1.

Leeds.—In the recently issued annual report, the significance of the outstanding benefaction of the year, a gift of £50,000 from an old student of the University, Mr. Frank Parkinson, is stressed: The object of the gift is to establish an endowment found for scholarships and it is noteworthy, apart from its magnitude, for the guiding principle prescribed by the donor for the administration of the fund. Education for citizenship is, he holds, a university's highest service to the community. His gift is intended "to fructify in the development of those types of manhood and womanhood which the country needs if it is to hold its place amongst the nations in the strenuous years that lie ahead", and he asks that in selecting beneficiaries the University be mindful of the supreme importance of "keeping the realities of life and the need for breadth of vision in human affairs well before its students".

Among the important developments of the year were the completion of the great new Library, the Brotherton, additions to the staff of the school of medicine and the inauguration of a scheme for closer co-operation with Yorkshire theological colleges. Student enrolments have steadily increased since 1930–31 and in the last session reached the record figure of 2,161 (full-time, 1,663). Nor do there seem to be grounds for fearing that the number is excessive in relation to the opportunities for employment open to graduates. On the contrary, year by year, says the report, we see an increasing reliance upon the value of university education on the part of the public.

Science News a Century Ago

Experiments with the Thermo-Electric Pile

ON April 24, 1837, writing from King's College, London, Wheatstone sent a note to the editor of the *Philosophical Magazine* (May 1837, 414) "On the Thermo-Electric Spark, etc." In this, he directed attention to some experiments recently made in Italy with Nobili's pile, the production of thermo-electric sparks and the effects of thermo-electric currents. The original experiments had been made by Cav. Antivori, director of the Museum at Florence, and Wheatstone had repeated them at King's College, where they were seen by Daniell, Faraday, Henry and Bache, of whom the last two were on a visit to Great Britain from the United States. The thermo-electric pile Wheatstone used had 33 elements of bismuth and antimony formed into a cylindrical bundle ⅘ in. in diameter and 1½ in. in length. The poles of the pile had wires leading to a mercury cup. One face of the pile was heated by a red-hot iron brought within a short distance of it, and the other was kept cool by ice. When contact was broken with the mercury cup, small sparks were observed. Writing of the results, Wheatstone said: "I conclude, therefore, that the experiment of Antivori is a real addition to our knowledge of electrical phenomena . . . it supplies a link that was wanting in the chain of experimental evidence which tends to prove that electricity, from sources however varied, is similar in its nature and effects, a conclusion rendered more than probable by the recent discoveries of Faraday. . . . It is not too much to expect, seeing the effects produced by a pile of such small dimensions, that by proper combinations the effects may be exalted to equal those of an ordinary voltaic pile."

Ornithological Society

THE first general meeting of this Society, which was formed on October 21, 1836, was held on April 26, 1837, at the Thatched House Tavern, St. James Street, with Mr. N. A. Vigors, M.P., in the chair. Since the last meeting, 127 new members had joined the Society, and the Duke of St. Albans, the Earl of Derby and other noblemen had made the Society presents of valuable birds. Several birds belonging to the Society had already been placed in the enclosure in St. James's Park; and the Committee intended to apply to the Government for a plot of ground for the use of the Society, on the plea that the hardy birds would be exhibited in the parks.

Changes in the Ova of Mammals

AT a meeting of the Royal Society on April 27, 1837, Richard Owen communicated a paper by Thomas Wharton Jones entitled "On the First Changes in the Ova of the Mammifera, in consequence of Impregnation . . ." The report of the paper said: "The author having in a former paper described the structure of the unimpregnated ovum of mammiferous animals, now proceeds to investigate the changes which the ovum undergoes in consequence of impregnation. In the rabbit, the first perceptible difference is the addition of a thick gelatinous matter surrounding the parts of which the ovum was composed in its original state, and apparently derived from the ovaries. In the progress of development the vitellary membrane gives way, as happens in the ova of the newt, and of many of the oviparous animals. The gelatinous envelope acquired in the ovary, and which is more especially circumscribed and defined after impregnation, constitutes the only covering of the vascular blastoderma, after the giving way of the vitellary membrane, and afterwards forms the chorion, which in rodent animals, at a further stage of development, presents itself under the form of a thin transparent membrane, very similar to the vitellary membrane of a bird's egg, and situated immediately outside the non-vascular and reflected layer of the umbilical or erythroid vesicle."

Brewster and Forbes

AMONG the letters of J. D. Forbes is one written on April 28, 1837, to Sir David Brewster, a part of which ran: "Your experiments on absorption must be most interesting. I think Wrede, the first pages of whose paper Taylor has lately translated, has done something of the kind you allude to, if I understand it correctly. If I recollect well, he imitates the phenomena of absorption by combinations of thin mica plates, that is by the colours of thin plates.

"I will do my best to capture a Wolf's lens for you, on condition that you will not require an affidavit that I saw the wolf make use of it. To stare a wolf in the face in the Black Forest would be enough to throw any optical philosopher into a fit of reflection."

The Zoological Society

THE anniversary meeting of the Zoological Society was held on April 29, 1837, at the Museum in Leicester Square, the Earl of Derby, president, being in the chair. The receipts for the year had been £19,123 14*s.* 10*d.*, of which £9,463 2*s.* 0*d.* was from admission fees to the garden; the receipts from this source exceeded those of the previous year by £2,000. The giraffes had been a great attraction. The Society had 3,050 members, with 43 candidates, 112 corresponding members, 24 foreign and 10 honorary members. During the year 363,392 persons visited the gardens. The total number of specimens were 1,025, of whom 307 were quadrupeds, 704 birds and 14 reptiles. The number of specimens in the Museum was 6,720, and there had been 3,668 visitors.

Medicine in Italy

THE April issue in 1837 of the quarterly *British and Foreign Medical Review* contains the following account from a correspondent of the state of medicine in Italy at that time.

"From what I have seen of the Italian physicians, I would remark that they display considerable learning and much acquaintance with ancient authors, yet in their practice they do not appear to advance beyond the days of Hippocrates or Galen. Following closely the footsteps of the great Father of Medicine, they closely watch the natural progress of the complaint, but unfortunately they do little either to assist or counteract the operations of Nature. In their practice they seldom employ anything like decision or vigorous measures to cut short disease, and even in the most acute complaints, they depend more on diet and regimen than on the use of medicines. I would not assert that they lose more patients than the English physicians; but I have no hesitation in saying that the bad effect of their mode of treatment is apparent in the immense number of chronic diseases which are continually presenting themselves and which might probably have been prevented from becoming such, had depletion been more freely resorted to in the acute stage of the disease."

Societies and Academies

Dublin

Royal Dublin Society, March 23.

D. A. Webb and W. R. Fearon : Studies on the ultimate composition of biological material. (1) Aims, scope and methods. A spectrographic survey has been made of peat from samples taken at different depths : (*a*) surface, (*b*) five feet down, and (*c*) twenty feet down. The following elements were plentiful in all samples : aluminium, calcium, magnesium, manganese, strontium. The following decreased with depth : lead, phosphorus, silver. The following increased with depth : barium, iron, silicon, zinc. The following were present as micro-constituents and showed no significant variation with depth : copper, molybdenum, potassium, tin. Surveys were made also of related organisms, namely, bakers' and brewers' yeast, and of various regions of a single structure, namely, the outer and inner layers of the testa and the endosperm of the Brazil nut. The data are discussed in connexion with the classification of biological elements into primary, secondary, and micro-constituents, and contaminants.

L. O'Droma and M. Grimes : A study of *Escherichia communior* found as a contaminating organism in 'starter'. A commercial 'starter' for use in cheese-making was found to produce a gassy curd. Manipulation of the mother starter failed to eliminate the gas former. Isolation revealed *Escherichia communior*, a coliform organism which ferments sucrose. Details of the cultural and physiological characters of the organism were given.

Paris

Academy of Sciences (*C.R.*, 204, 829–924; March 15).

Lauge Koch : The question of the Ozakian in Greenland. The arrangement of the strata in northern Greenland is tabulated, in accordance with the author's view. The upper Cambrian is not represented, and the term Ozakian is omitted as being unnecessary.

Maurice Nicloux : The diffusion of ethyl alcohol in marine animals, and the hypothesis of combined water. Experiments bearing on the hypothesis of the existence of a protein-water complex in which the water has lost its usual solvent properties.

Mendel Haimovici : Finsler spaces.

Christian Pauc : Ensemble of finite systems of points of a continuum.

Lubomir Tchakaloff : A problem of Laguerre.

Maurice Potron : Non-negative matrices.

Henri Milloux : The Schottky-Landau theorem and the theory of normal families of functions.

Robert d'Adhémar : The elementary theory of the gyroscopic movement of projectiles. Nature of the approximation. The Magnus effect.

Jean Louis Destouches : The properties of the generalized Lorentz transformation.

Ouang Te-Tchao : The size of smoke particles suspended in the air.

Raymond Chevalier and Mlle. Suzanne Mathieu : The variation of the magnetic susceptibility of a hæmatite powder as a function of the size of the grains. The magnetic susceptibility diminishes regularly as the grain size is reduced. No explanation can be given at present.

Roger Servant : The examination and working of quartz plates cut perpendicularly to optic axis.

Marcel Châtelet : The kinetics of the oxidation of cobalt in ammoniacal solution.

Marcus Brutzcus : Combustion yields of hydrocarbons and energy values of the linkages of their atoms.

Mme. Alma Dobry : The electro-chemical nature of cellulose solutions.

Marcel Servigne : A sensitive method for detecting traces of rare earth elements. The method is based on the production of a photo-luminescence spectrum, and will detect certain rare elements (samarium, dysprosium, europium) in concentrations so low as one part in a million.

Pierre Bonneman : The tetrametaphosphates.

Armand Marie de Ficquelmont : The mechanism of the polymerization of the phosphonitril chlorides, $(Cl_2PN)_x$.

Thadée Urbanski and Marian Slon : The nitration of the paraffin hydrocarbons by means of nitrogen peroxide. With normal paraffins ranging from pentane to nonane, mixtures of mono- and dinitro-derivatives were obtained.

Jacques Parrod : The influence of some compounds on the formation of hydrocyanic acid, by oxidation of lævulose or of alloxan, in a copper-ammonium medium.

Eugène Wegmann : The Precambrian base of southern Greenland.

Louis Eblé : The values of the magnetic elements at the Val-Joyeux (Seine-et-Oise) station on January 1, 1937.

Emile Thellier : The so-called permanent magnetization of basalts. The magnetization of a basalt is altered by the action of even a very small magnetic field. Hence researches on the variations of the terrestrial magnetic field with time based on the study of the magnetic properties of basalts are of doubtful validity.

Robert Lemesle : A new secreting apparatus with tannoids in the genus *Eupomatia*.

Robert Echevin and Arthur Brunel : Nitrogen metabolism in the course of the germination of the lupin, *Lupinus albus*.

Roger Ulrich : Some factors of the premature fall of the fruit in the ivy (*Hedera Helix*).

Robert Quetel : The evolution of various forms of phosphorus in forced lily-of-the-valley.

Roger Gautheret : The action of the root on the survival of isolated cells of the cap of *Lupinus albus*.

Marcel Mascré : Leucænol, a definite principle extracted from the seeds of *Leucæna glauca* (Papilionatæ).

René Souèges : The embryology of the Amarantaceæ. The development of the embryo in *Amarantus retroflexus*.

Marc Simonet : A new case of chromosome division in a hybrid of *Iris pogocyclus*, *I. Ricardii* var. *Leverrier* × *I. Iberica*.

Jules Pavillard : Hybridization (or perhaps mutation) in pelagic diatoms of the genus *Rhizosolenia*.

Maurice Rose and Mlle. M. Hamon : The physico-chemical conditions of bursting and of th dehiscence of the spermatophores of some Cephalopods.

Mlle. Yvette Neefs : Various cases of functiona hermaphrodism in *Strongylocentrotus lividus*.

Wladimir Drabovitch and Pierre Weger : Tw cases of experimental neurosis in the dog.

Paul Chauchard: Chronaximetric analysis of the mechanism of the synergic and antagonistic actions in the field of the autonomous nervous system.

Philippe l'Héritier, Mlle. Yvette Neefs and **Georges Teissier**: Apterism of insects and natural selection.

Maurice Lecamp: The morphological determination of the regeneration of members in the *Phasma*.

Mme. Paulette Chaix: The influence of traces of oxygen on the glycolysis of *Propionibacterium pentosaceum*.

Mme. Andrée Drilhon: The influence of parasitism on the mineral equilibrium of the tissues (sacculine in the crab).

Mlle. Gilberte Mourot: The nature of the excremental compounds resulting from the catabolism of the amino acids.

Iwo Lominski: Is alexin a corpuscular element ?

Georges Blanc and **M. Baltazard**: The influence of fasting on the persistance of the virus of typhus in the flea, *Xenopsylla cheopsis*.

Georges Mouriquand, Henri Tête, Georges Wenger and **Paul Viennois**: Rheumatism with anchylosis in partial C avitaminosis.

Cracow

Polish Academy of Science and Letters, February 8.

S. Mazurkiewicz and **Mlle. H. Szmuszkiewicz**: The zeros of quasi-analytical functions (*B*).

Th. Banachiewicz: The calculations of determinants with the aid of Cracovians (2).

W. Swietosławski and **E. Ramotowski**: Distillation with simultaneous expansion of vapours. Results obtained with an apparatus consisting of four fractionating columns connected by four narrow jets, producing differences of pressure in the four columns. The separation is more efficient with the expansion than without it.

W. Swietosławski and **S. Pieszczek**: The comparative method of determination of the critical temperature of liquids and their mixtures.

K. Dziewonski and **L. Sternbach**: Studies on pyrene.

J. Tur: The extent of the neoplasmogenic action of blastodermic cauterization.

J. Gallera: The teloblast of platyneuric embryos.

Washington, D.C.

National Academy of Sciences (*Proc.*, **23**, 41–131, Feb. 15).

K. W. Cooper: Reproductive behaviour and aploid parthenogenesis in the grass mite, *Pediculopsis raminum* Reut. (Acarina, Tarsonemidæ). After ttachment to the source of food, the hysterosoma of he female swells with fluid to 100–500 times the original body volume of the mite ; eggs form within, nd develop through larval and nymphal stages to dults, when mass birth occurs. Such mass births ntain about 5 per cent of males ; a male is inariably present in every brood. Copulation often ccurs before the mass birth. Virgin females, isolated efore birth, produce only males, which seem to be aploids (chromosome number, 3).

A. V. Manza: The genera of the articulated rallines.

Chester Stock: An Eocene titanothere from San iego County, California, with remarks on the age ' the Poway Conglomerate.

A. G. Steinberg: Relations between chromosome size and effects of inversions on crossing-over in *Drosophila melanogaster*. The effect of an inversion on crossing-over in a non-homologous chromosome is a function of both the inversion itself and of the length of the chromosome affected.

Helen D. King and **W. E. Castle**: Linkage studies of the rat (*Rattus norvegicus*) (2). The occurrence of waltzing in an inbred race of rats at the Wistar Institute is linked with albinism, and its gene is now found to be borne in the same chromosome as the albino gene.

H. H. Laughlin: The coefficient of prediction-accuracy : computation of the portion of individual cases common to both the particular prediction-distribution and to the subsequently determined actual-distribution of the same measured and counted phenomena.

W. J. Crozier: Strength-duration curves and the theory of electrical excitation. Data on the relationship of current strength and time for a fixed magnitude of effect due to repetitive electrical excitation in nerve and muscle, and also data on phenomena of stimulation by light and by sound, can be described by a logarithmic probability integral.

H. Rademacher: A convergent series for the partition function $p(n)$.

J. L. Walsh: Curvature of level curves of Green's function.

A. H. Clifford: Representations induced in an invariant subgroup.

S. Pasternack: The mean value of r^s for Keplerian systems.

Paul S. Epstein: The equation of diffusion. A discussion of two equations for a general theory of diffusion published by Kolmogoroff under the title "The Analytical Theory of Probability" and their relation to other forms of the diffusion equation used in physics.

Th. von Kármán: The statistical theory of turbulence.

F. Zwicky: Intrinsic properties of light and corpuscles from distant sources. The importance is stressed of investigating the change in time of dimensionless ratios of significant physical quantities. Data already available indicate that nebular light and terrestrial light possess intrinsically identical physical properties. Certain recent observations, however, suggest that the velocity of light may depend on its frequency. Similar inquiries should be made with regard to extra-terrestrial corpuscles.

Dorrit Hoffleit: Spectroscopic absolute magnitudes of three hundred and seventy southern stars.

T. E. Sterne and **L. Campbell**: Changes of period in variable stars of long period. A study of the data available for 377 variables by Pearson's χ^2 test indicates that while certain of them have sinuously changing true periods, there is no good evidence for any secular change of period of an evolutionary nature among long-period variables as a whole.

D. E. Adelson and **M. T. Bogert**: The synthesis of gamma-methyl-5,6-cyclopentenoretene, a compound structurally related to 'Diels' hydrocarbon'. It is thought this substance may be of biological interest.

W. D. Harkins: The intermediate nucleus in the disintegrative synthesis of atomic nuclei : disintegration in steps. A discussion of various nuclear reactions based on the view put forward in 1926 that one or more intermediate nuclei are first formed, each of which has an actual life and separate existence.

Forthcoming Events

Tuesday, April 27

INSTITUTION OF CIVIL ENGINEERS, at 6.—Sir William Bragg, F.R.S.: "The Crystal and the Engineer" (James Forrest Lecture).

Wednesday, April 28

ROYAL SOCIETY OF ARTS, at 8.15.—Lieut.-Colonel G. P. Pollitt: "Recent Developments in Grass Drying".

Thursday, April 29

BRITISH PSYCHOLOGICAL SOCIETY, at 8.30.—Dr. William Brown: "Hypnosis, Suggestibility and Progressive Relaxation. An Experimental Study".

Friday, April 30

SOCIETY OF CHEMICAL INDUSTRY (CHEMICAL ENGINEERING GROUP), at 6.45—(at the Waldorf Hotel, Aldwych, London, W.C.2).—Annual General Meeting.

Sir Alexander Gibb, F.R.S.: "The Chemical Engineer and Industrial Planning".

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ENGINEER AND MANAGER of the Caledonian Canal—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1 (April 30).

HEAD OF THE BUILDING DEPARTMENT in the East Ham Technical College—The Secretary for Education, Education Office, Town Hall, East Ham, E.6 (May 7).

LECTURER IN MECHANICAL ENGINEERING in the Derby Technical College—The Clerk to the Governors, Derby Technical College, Green Lane, Derby (May 10).

ADDITIONAL ZOOLOGIST on the Scientific Staff of the "Discovery" Committee—The Secretary, "Discovery" Committee, Colonial Office 16 Queen Anne's Chambers, London, S.W.1 (June 1).

GENETICIST for the Rubber Research Scheme, Ceylon—The Chairman, Rubber Research Scheme, Agalawatte, Ceylon (June 30).

ENTOMOLOGIST for the Iraq Government—The Iraq Legation, 22 Queen's Gate, London, S W.7

LECTURER IN PHYSIOLOGY in Loughborough College—The Registrar.

ASSISTANT LECTURER IN ENGINEERING and ASSISTANT LECTURER IN BUILDING in the Swansea Technical College—The Director of Education, Education Offices, The Guildhall, Swansea.

TEACHER OF MINING SUBJECTS in the Whitwood Mining and Technical Institute—The Secretary to the Managers, Education Offices, Castleford, Yorks.

RADIO RESEARCH WORKER for the National Research Council, Ottawa—The Secretary-Treasurer.

The Imperial Forestry Institute, Oxford

THE future policy of the Imperial Forestry Institute, Oxford, is set out in its twelfth annual report—the first issued since the new scheme of management was introduced. Briefly, it is proposed "to develop the Institute as a centre for the study of world forestry in relation to Empire forest problems and as a forum for the interchange of professional knowledge amongst foresters from all parts of the Empire, rather than as a place of instruction *ex cathedra*". Every opportunity is to be taken of maintaining a closer liaison with the services concerned. It is hoped that ultimately it may be possible for forest officers from different parts of the Empire to be seconded to the Institute for the purpose of giving instruction.

In the meantime, it is proposed to make the fullest use of the fund of knowledge and experience brought to the Institute by the constant stream of forest officers and research personnel who visit it for refresher courses or other purposes, by drawing upon it systematically and placing the results on record. The staff of the Institute will not only act as *rapporteurs* of experience brought to the Institute, but also study and analyse the various techniques of utilization, sylviculture, land conservation and improvement, and their reasons for success or failure, in the light of the fundamental sciences applicable to them. They will carry out research, especially team research, by which plant physiology, soil science, ecology, systematic botany and other sciences may be applied to the solution of complex problems. It is considered axiomatic that the teaching given should be based on research carried out by the staff.

In order that the staff may be better fitted to carry out the role assigned to them, it is essential that they should have some first-hand knowledge of forest conditions in the Empire at large, and opportunities of establishing contact with other workers overseas. It is hoped that it will be feasible, ultimately, to arrange for members of the staff to make tours of some length, during which the duties of the member of the staff on tour will be carried out by a *locum tenens* from some other part of the Empire. Meanwhile, as a beginning, financial provision has been made for one of the senior members of the staff to undertake such a tour.

The fullest development of the Institute as a centre for the diffusion of knowledge by personal contact, implies not only the interchange of knowledge between the permanent staff and visiting officers of experience, but also between the students themselves. One important suggestion from this point of view has been put forward to the Colonial Office, namely, that the year's course at the Institute taken by probationers before taking up their posts in the services to which they are appointed, should be postponed until they have completed an apprentice tour of, say, two years. Their experience, though limited, would enable them to appreciate more fully the problems they have to face than can be expected from any student without experience of tropical conditions. They would be in a position to concentrate on these problems, compare notes with their fellow students from other territories, and refer difficulties to the Institute's staff and to more experienced officers undergoing refresher courses.

Whilst the dissemination of knowledge by personal contact will form such an important feature of the activities of the Institute, it will also, so far as its financial resources permit, act as a clearing house for information on world forestry available in documentary form. As a beginning, the practice of scanning all incoming forestry literature and indexing important contributions has been resumed in a modified form, involving the use of the 'Flury' international decimal classification and the issue, to the services, in multigraphed form, of a *Current Monthly Report*. There is some hope that an Imperial Forestry Bureau may be set up under the Imperial Agricultural Bureau scheme, and attached to the Institute.

With regard to the subjects to be included in the curriculum of the Institute, it is intended to provide more teaching of economics, as the basis of forest utilization and management, and of ecology, plant physiology and soil science as fundamental to the study of sylviculture, not only on the productive side, but also in the widening field of the protective and reclamatory influences of vegetation. The main object, on the teaching side, is to make the initial training and refresher courses more useful to serving forest officers.

Points in the report which may raise questions in the minds of scientific foresters, are the tendencies to emphasize economics as against sylviculture, and to minimize the importance of the study of European forestry as part of the training of a forest officer. It is proposed to hold the study tour of the present year in Finland, on the ground that the highly specialized forms of forestry of Germany, France and Switzerland, seen in the usual study tours, have little application to average conditions overseas. Though, in a literal sense, this contention is true, the forestry of these countries provides the finest examples available of the adjustment of forestry practice to local conditions, and the field in which the ecological, economic and sociological foundations of forestry have been most fully worked out. Students in British forestry schools probably receive sufficient grounding in European forestry, but those officers whose training has been outside Europe should be given an opportunity of making a first-hand acquaintance with the finest examples. Finland is an excellent field for the special study of the economics of exploitation in conditions which are analogous to those of parts of the Empire in some respects, but even more remote in others (climate, number of species, etc.).

The practice of arranging special tours for individuals wishing to study particular aspects of forestry is an important feature of the Institute's work, and it is recognized that it is desirable to extend them into the nearer tropics and even the United States of America on occasion. The advisability of making the Scandinavian countries the venue of ordinary instructional tours is more doubtful.

The policy outlined in the report should commend itself to the forest services of the British Empire, and it is to be hoped that the financial and other support, necessary to implement it fully, will be forthcoming.

Application of Medical Science in Tropical Countries

A Doctor's Odyssey:
Adventures in Forty-five Countries. By Dr. Victor Heiser. Pp. 547. (London: Jonathan Cape, Ltd., 1936.) 15*s*. net.

ABOUT few books can it be said that they have the combined qualities of being interesting, elevating and amusing; but such a claim can certainly be made in the case of Dr. Victor Heiser's book. Dr. Heiser has passed a wonderful life, first in developing the public health service in the Philippines at the time when the United States of America took over these islands, and, at a later date, as one of the executive officers of the Rockefeller Foundation, whose mission it was to organize measures for the suppression of tropical disease, and especially of hookworm infestation, in many parts of the world.

There are probably not many people who realize the extent to which preventible disease develops in tropical countries—plague, smallpox, malaria, typhoid and typhus fevers, hookworm disease, and many other disorders. On arriving at the Philippines, Dr. Heiser says, "I set myself the goal of trying to save 50,000 lives a year." Such a statement may seem grotesque to the average reader, but there is no doubt at all that the Health Board more than succeeded in this object. Millions of people die of these diseases, and those who survive are usually crippled in one way or another for life, in spite of the fact that the knowledge for suppressing most of them is available. In India alone there are said to be 100 million people suffering from malaria. What are we to think of this state of affairs? If human life and health are sacred and precious, why is no united effort made to eliminate or at least to control these death-bringing diseases ? Why are such efforts left in the hands of a few people who, however successful, may have their work hindered, or even stopped, at any moment by the whim of the politician or political administrator ? A good instance of this kind of interference in public health administration is given by Dr. Heiser when he deals with the period of Governor Harrison's presidency over the destinies of the Philippines. Harrison believed that the natives of a country ought to control their own legislation and administration, even in the case of malaria and plague prevention. It can be readily imagined what these primitive people thought of sanitation and clean houses ; and only after the death-rate had again mounted to enormous figures was it decided that a proper standard of health was incompatible with home rule founded on ignorance, superstition and vested interests. The American medical men again got their chance with the arrival of a new governor.

The kernel of the matter is that eighty per cent or more of all social and political problems of tropical countries are essentially biological in nature. When politicians and administrative officers recognize this fact and encourage the medical scientist and biologist to the utmost, many difficulties of administration will disappear, and the standard of health and mental development in these countries will be completely revolutionized.

But it is not only politicians who will profit by reading this book. It might be of some advantage to that large number of people, even educated people, whose idea of modern science centres around aeroplanes, high explosives, poison gas, and the metaphysical interpretations of mathematico-physics sponsored by our modern scientific Schoolmen. It is representatives of this group who state so frequently from the pulpit and through the medium of the British Broadcasting Corporation on Sunday evenings that "modern science has failed".

It will be evident that Dr. Heiser not only had his chances but also that he seized them with both hands. In the Philippines, at least, he seems to have met with almost unreasonable success in most things he attempted, apart from the Governor Harrison episode referred to above. This success was, according to his own account, often due not so much to his own skill as to the fact that most people who stood in his way seemed to be not only slightly weak-minded but completely complacent. In my experience, obstruction and complacency in public life do not generally go together, but Dr. Heiser wins through most of his difficulties and pleases everybody, including the reader of his adventures.

Dr. Heiser is a man to whom things 'happen', as I suppose they happen to most of us at times ; but he also has the faculty of remembering the incidents, and sufficient humour to appreciate them. About whom but Dr. Heiser could the following incident revolve ? He had a quarantine officer called Dr. Turnipseed, and it was the duty of this Dr. Turnipseed to board a ship one morning for quarantine purposes. He knocked on the captain's cabin door and said, "I am Dr. Turnipseed," to which the answer was, "Well, you have nothing on me, I am Captain Garlic."

The book is full of amusing incidents and suggestions. For example, at one time Dr. Heiser was travelling in a ship which was infested with cockroaches. These cockroaches used to run over the feet of passengers when they were asleep, so that if they had corns these were neatly removed by the cockroaches, who gnawed down until they reached a sensitive spot on the foot, when they would be automatically shaken off by the disturbed patient. What chiropodist could compete with this perfect and costless procedure ?

But, however light the tone adopted by Dr. Heiser in describing his life's work, it must be realized that he is really dealing with the fundamental problem of extending modern knowledge to combating disease and death. The fact that he has written in this most acceptable form must not be regarded as evidence of the lack of seriousness of purpose in his endeavours. The general reader will enjoy reading this book greatly, but for those with an intimate knowledge of tropical medicine the fun will not be so unadulterated. The expert will often be made to jump by the cleverly concealed but obvious egotism of the author and by his wrong appraisal of the relative importance of some medical discoveries. Will, for example, Dr. Heiser kindly remember in discussing beriberi in any future edition, that Eijkman is a figure reverenced by all with real knowledge of nutritional disease ? Still, it is improbable that a book of such excellence could have been written by anyone who had not the failings as well as the good qualities of Dr. Heiser.

Now that Dr. Heiser has retired from the tropics and returned home, the Government of the United States ought to put him in charge of a campaign to attack the dreadful situation of venereal disease in that country. If it is true, as stated by those with intimate knowledge, that there are 681,000 new cases of syphilis annually in the United States, it is high time that somebody with Dr. Heiser's qualities for successful administration in preventive medicine should tackle this scourge of public health. E. MELLANBY.

The Tsetse Fly Problem

The Tsetse Flies of East Africa:
a First Study of their Ecology, with a View to their Control. By C. F. M. Swynnerton. (Transactions of the Royal Entomological Society of London, Vol. 84.) Pp. xxxvi + 579 + 22 plates + 7 maps. (London: Royal Entomological Society, 1936.) £5 10*s*. 0*d*.

THE greater part of tropical Africa is covered by the range of one or more of the twenty-one species of tsetse fly (*Glossina*) indigenous to that continent. In much of this vast territory it is not possible to keep cattle owing to the ravages of nagana disease, while the human population is being decimated by sleeping sickness. It is well known that the trypanosomes responsible for these diseases are carried by one or other of the species of *Glossina*. The future prosperity of great tracts of the African continent depend, therefore, on discovering means by which such areas can be inhabited by man and his domestic animals free from risks of infection by these diseases.

Mr. C. F. M. Swynnerton, director of tsetse research in the Tanganyika Territory, has now provided the most comprehensive detailed compendium on the problem that has yet appeared. Published by the Royal Entomological Society with the aid of a monetary grant from the Tanganyika Government, it runs to nearly six hundred pages, with a table of contents alone extending to thirty-six pages. It will be understood, therefore, that it is far too detailed and lengthy for anything more than a very general notice in these columns.

In Tanganyika, two-thirds of the Territory is under infestation by tsetse; and over the remaining one-third, infestation is rapidly spreading. Mr. Swynnerton's problem is how best to rid the land of the scourge of *Glossina* by a reasonable expenditure of money and labour. His equipment for this campaign has amounted to £15,000 per annum, with a European staff of three entomologists, a zoologist, botanists, field officers, etc., together with an office staff of Asiatic clerks. His method of attack is to concentrate on intensive research in co-operation with experimental reclamation of defined areas. The striking success that his methods have already produced is the best argument that his schemes deserve the fullest support from all concerned with the welfare and administration of a great Territory. His policy is to study the ecological requirements of each species of tsetse with the view of depriving it of the minimum necessary for its existence. It appears that each of the eight species of *Glossina* present in Tanganyika needs a concurrence of different vegetational types. If, therefore, any essential type is modified or destroyed, to a required degree, the tsetse is no longer a menace in a given area.

Mr. Swynnerton's bulky volume is a great storehouse of tsetse ecology treated from every point of view. Each species of the fly presents its own series of problems while sub-problems seem to be innumerable. *Glossina morsitans*, for example, affects seven different types of country, each of which requires individual consideration. The term environment includes not only vegetation but also nearly the whole of the vertebrate fauna of a given area. Domestic animals, man and his operations and practices, soil conditions, climate and its smaller units, native settlement, besides matters of medical and veterinary concern, are also comprised within the comprehensive term environment.

Mr. Swynnerton lays down the axiom that effective attack on the fly in the bush offers the only full solution. In the first instance, after the making of a thorough preliminary study, it is necessary to form barriers for enclosing great tsetse-infested areas of bush. Once these barriers have been established, the destruction of the tsetse in the main bush has to be taken in hand. Complete clearing is objectionable not only on grounds of expense but also on account of the erosion which results. Discriminative clearing is therefore to be aimed at. As regards barriers, it is considered that cleared zones two miles wide will be permanent. Barriers formed by certain types of thickets also prevent the crossing of the fly, evergreen thickets being effective in narrow width. Barriers of deciduous thickets are also advocated, but they need to be of considerable width. Apart from the application of the foregoing measures, direct attack on flies by trapping and other means is only likely to be effective in limited areas. An intensive field study of each species of tsetse is stressed, and this needs to be followed by laboratory analysis of the factors involved. Good progress has already been made in this field with the aid of a number of workers.

The connexion between different kinds of tsetse and the wild game, and other fauna, is a great problem in itself. Mr. Swynnerton points out that the only form of game destruction, likely to prove of benefit at all, is highly organized hunting directed by Europeans—otherwise it is useless or directly harmful. Organized game hunting, however, is only feasible in types of more open wooding but not in dense thicket. It also involves great expense which is liable to grow into an indefinite commitment.

Once areas are cleared and reclaimed, problems of native settlement then arise. All means, also, have to be employed to prevent re-growth of vegetation. Co-operation of the natives themselves is essential, and in this respect Mr. Swynnerton's personality has already worked with great success among the peoples of Tanganyika.

Our congratulations go to Mr. Swynnerton. By his boundless energy and enthusiasm, the way is now pointed towards the solution of a great problem in this Territory. His encyclopædic document will prove a boon, as a storehouse of information, that will also guide and stimulate workers in other parts of the continent of Africa menaced by the tsetse.

A Programme for the Social Sciences

The Science of Social Adjustment
By Sir Josiah Stamp. Pp. vii+174. (London: Macmillan and Co., Ltd., 1937.) 7*s*. 6*d*. net.

IT needs no more than the painful experience of the Special Areas or a study of the social and industrial surveys of South Wales and Merseyside, with which the University of Liverpool and University College, Cardiff, have recently been associated, to demonstrate how sadly we need to develop a science of social adjustment. If under this new title Sir Josiah Stamp had merely given us his earlier valuable addresses on the calculus of plenty and the impact of science upon society, we might have welcomed this book for its further stimulus to much overdue action in this field. He has, however, done more. The theme of his recent presidential address to the British Association has been expanded by rearrangement and additions, and with the revised lectures on eugenic influences in economics and on the calculus of plenty, we are given three successive chapters in which his argument is continuously developed until he comes to consider in the final chapter some projects for research.

Wherever and whenever new science touches society, it creates a disturbance which has hitherto been mostly accepted as inevitable, but is often a high price for progress. The study and control of this impact constitute the science of social adjustment, and Sir Josiah's insistence that this is no new problem but one that has been with us in lesser degree for centuries does not encourage continued neglect, but calls more imperatively to action. Indeed, Prof. A. N. Whitehead's assertion that we are living in the first period of human history for which we can no longer assume that each generation will live substantially amid the conditions governing the lives of its fathers, and transmit those conditions to the succeeding generations, is emphatically endorsed.

For all this, we have no adequate technique of change, and treat life as mainly static with occasional and exceptional periods of change, instead of regarding it as continuously changing with occasional and abnormal periods of rest, and we have to secure all the changes of social outlook implied by that reversal of view. Even if we have come to accept change as normal and not the exceptional, we are still faced with the fact that it is almost impossible to predict what social life would be under a very different regime. The decay of social cohesion caused by industrial growth, the increased severity of industrial depressions could scarcely have been predicted in any detail. With T. N. Whitehead in his "Leadership in a Free Society", Sir Josiah reminds us that foresight at long range is not possible when dealing with anything so complex as a modern society.

Sir Josiah, however, does not leave us with a purely negative diagnosis; though he makes no proposals for action, he puts forward theories of proposals which are the working hypothesis as a basis for research and fact-finding. Essentially his book is a challenge to thought, and whereas Whitehead has primarily thrown down a challenge to leaders in industry to accept the responsibility of supplying social leadership to repair the disintegration which industry is working in society, and to see industry as essentially a part of society, Sir Josiah's challenge is rather to academic thought. He warns us indeed that economic life must pay a heavy price, in this generation, for the ultimate gains of science, unless all classes become economically and socially minded, and large infusions of social direction and internationalism are carefully introduced. The emphasis above all, however, is on the quality of thought. "A great draft on the highest mental ability for such social studies is essential." Courses in social science should be as difficult and call for as much thought and scholarship as any of the natural sciences. They are in many senses more exacting in thought processes because they cannot employ the same concrete methods available in the physical sciences.

This emphasis on the need for sustained economic analysis by more first-class minds does not mean government by scientific technique or any other transferred technique, appropriate as these may be to the physical task of production. When the requisite facts have been assembled and analysed, the leadership required must take account also of social wisdom and allow for the slow and halting development of interlocking human relations. Even in this era of change, the motives ensuring predictable and organized activities are the social sentiments surrounding accustomed routines.

It is, however, in presenting a programme for research that this book has the widest claims on the interest of scientific workers. Throughout the book and not only in his final chapter, Sir Josiah gives us examples of lacunæ in existing knowledge which adequate research in eugenics and economics could fill, and in the absence of which a wise direction of national affairs is scarcely possible. He reiterates proposals for research into population changes and distribution, recommending the establishment of a Royal Commission to examine and report upon the probable consequences of the decline in population and change in age groups, and to recommend upon the measures required. He urges a new view of census responsibilities, a census every five years with allied studies of unemployment and of educational adjustments of major significance.

A further proposal is the development of a practice, by the responsible body in each branch of science, of reviewing periodically the immediate *hinterland* of its subject, setting out for each period the chief discoveries, their application, effect on employment and location of industry and the like. He adds another voice to the many who in the last ten or fifteen years have questioned the fundamental suitability of the present patent system to industrial conditions to-day. He suggests very tentatively the possible advantage of confining all patent protection to a six-year period, and urges strongly the need for careful research into the record of recent invention and into the existence of economic and human waste and disturbance in the direction and stability of industry. Scientific research of a close inductive type is required to determine how far the penetration of inventive ideas is fortuitous and dependant on reaching the right man and the right purse at the right time.

Obsolescence provides yet another subject for research which should be approached from the social point of view, and over the last twenty years might provide a model picture and give the basis for a proper treatment. The investigation of taxation adjustments, the co-ordinated study of human heredity and the selective direction of financial support in research are other matters drawing strong support from Sir Josiah, who pointedly directs attention to the disparity between research resources both in men and finance, in the economic or social fields and those available for the physical sciences. University scholarships in the social sciences are negligible in number compared with those given in classics and humanities, and while not suggesting that any of the social sciences should be made school subjects, he pleads for further scholarships in such sciences or a redistribution of funds which will encourage the supply of competent research workers in these fields. Sir Josiah also urges pertinently that to determine, for example, whether a considerable element of under-employment is or is not actually and preventably inherent in the present industrial and economic system is a first-class issue much transcending in importance any current problem in physics or engineering. The resolute and vigorous analysis of the "Douglas Credit" diagnosis of deficient purchasing power, of J. A. Hobson's theories of under-consumption dependant upon maldistribution of income, and of J. M. Keynes' equation between saving and investment and of his analysis of the "propensity to consume" and the issues raised by them, are other examples cited as deserving the attention of a considerable number of thinkers of the front rank. Finally, he raises the question of the various forces which decrease the mobility of personnel in industry, and allied problems—the need for research on the psychological reaction to unemployment relief in relation to the incentive for seeking work, to change of occupation and readiness to train for such changes or to accept a change of neighbourhood—and the social consequences of our facilities for technical education, and its relation to industrial and social activity.

To those who believe that the problems of to-day can only be dealt with by a radical transformation of the nature of society, even if revolutionary, Sir Josiah Stamp's programme for study and development of a science and technique of social adjustment may be of little interest. To those, however, who believe in the possibility of a step-by-step advance, in the development of a mental attitude or discipline competent to guide society through habitual change in an orderly manner, in man's capacity if wisely guided to develop once more the powers required for mastering his environment, it is a challenge both to thought and action. It should win the sympathy and support of even the most ardent protagonist of the physical sciences, to make his own contribution to the great redistribution of our scientific resources and research effort involved when we seriously undertake the programme of social adjustment.

R. BRIGHTMAN.

A Manual of Pharmacology

By the late Dr. Walter E. Dixon. Revised by W. A. M. Smart. Eighth edition. Pp. viii+483. (London: Edward Arnold and Co., 1936.) 18*s.* net.

W. E. DIXON'S well-known text-book has long enjoyed a wide popularity. It is almost the only text-book of pharmacology in the English language of suitable length for those students who regard pharmacology merely as one of the obstacles on the road to a medical qualification. It has always contained a spice of unorthodox and entertaining information which has delighted its readers, and sometimes puzzled their instructors. The seventh edition appeared in 1929, and is now out of date. The eighth edition, prepared by Dr. W. A. M. Smart, represents a drastic revision. The number of figures has been reduced from 97 to 79, but the figure which appears to portray inhibitory nerves to voluntary muscle has been retained.

A large number of chemical formulæ have been inserted, so that it is now possible to find the structure of nearly all drugs of importance. These formulæ are useful for reference, but the detailed chemical structure of most of these substances throws little light on their action, and a knowledge of these details is really only of value to those engaged in research. The bulk of the book has been reduced by the use of a thinner and better paper, but the number of pages is about the same. The general arrangement has not been altered, and the allocation of space to different sections is about the same as before. The chapter dealing with vitamins, hormones, vaccines and sera occupies only fourteen pages. This section might well have been expanded.

It cannot be said that this new edition represents a reliable guide to all the drugs in common use today. There is no mention of the agranulocytosis caused by pyrazolon derivatives or of the action of plasmoquine on the sexual forms of the plasmodium, or of coramine, or dinitrophenol. Salyrgan and mersalyl appear as two different substances. The section dealing with the chemical structure of the cardiac glycosides contains no reference to the cyclopentenophenanthrene skeleton. On the other hand, the book is still the most attractive of its kind. The use of different types for subheadings makes reference easy, and the introduction of a number of prescriptions will probably be a popular feature.

A Modern Biology

By Ernest J. Holmes and Dr. R. Darnley Gibbs. Pp. xvi+272. (Cambridge: At the University Press, 1937.) 3*s.* 6*d.*

THE introduction of biology into the school curriculum and the School Certificate examination syllabus has resulted in the production of many text-books, several of which tend to regard biology as a mixture of botany and zoology. To many biologists, the division of the subject is regrettable, and the question has been raised whether it is possible to teach biology to a pupil of school certificate stage. It is much easier for a young pupil to grasp concrete facts about specific plants and animals than to grasp generalizations, but if biology is really to be appreciated then these generalizations must be grasped.

This book is a praiseworthy effort to establish biology on its own feet instead of on botanical and zoological crutches. The subject matter is treated biologically throughout, and in no place is there an obvious separation made into plant and animal work. The result is a very readable book on which it should be possible to base a good course in biology. The authors indicate in their introduction that the book is intended to succeed a course in nature study, in which it is assumed that many structural features of plants and animals will have been studied. On this foundation the authors have built a course, the theme of which is function rather than structure.

The book is well produced, well printed, and beautifully illustrated. At the end of each chapter are suggestions for practical work based on the subject matter of the chapter. The treatment of the subject matter is modern and refreshing, and should be read and carefully examined by every teacher of school biology.

The Hair in Health and Disease:

a New Explanation of Diseases of the Hair, Scalp and Skin and of "Barbers' Diseases" in Particular. By Edward Lawrence. Pp. xvi+181. (London: Sir Isaac Pitman and Sons, Ltd., 1936.) 5*s.* net.

THE author of this book is a barber, and he feels that barbers have been badly treated. They have been punished for being dirty and spreading infectious diseases. Stirred by a strong sense of injustice, he says that 'barbers' rash' is not due to germs, and that diseases in general are not due to micro-organisms but to heredity. He adds that medical men, who have testified against barbers, may themselves be responsible for conveying the infection of puerperal fever. He counters dogmatic statements with the lie direct. The relative importance of the different possible factors in the causation of such diseases is not in fact known with certainty. Scientific workers in general are more open-minded than the author supposes, but they are not likely to be convinced by rhetoric.

Statistical Methods for Research Workers

By Prof. R. A. Fisher. (Biological Monographs and Manuals.) Sixth edition, revised and enlarged. Pp. xiv+339. (Edinburgh and London: Oliver and Boyd, 1936.) 15*s.* net.

THIS book has done more than any other to popularize the use of modern statistical methods. Thousands of workers have been taught to use statistical machinery without the burdensome necessity of knowing exactly how it works. Six editions have appeared in twelve years, and the number of pages has been steadily increasing. To facilitate reference the numbering of the sections has been kept constant. It would be convenient if the numbers of the sections could be printed at the top of each page. The book maintains its place as the standard work on its subject for the ordinary scientific worker.

Water-Power Developments in the United States

By Dr. Brysson Cunningham

I

THE United States Geological Survey, among its other activities, renders an important service to hydrological science by collecting and publishing information on the amounts of developed and potential water-power throughout the world, the returns of the former and the estimates of the latter, of course, requiring periodical revision as the development of water-power proceeds. From the latest statement issued by the Survey, it is to be gathered that the total amount of horse-power actually harnessed at the end of 1934 was 55 millions, as compared with 46 millions in 1930, 33 millions in 1926, 29 millions in 1923, and 23 millions in 1920—an increase of nearly 140 per cent in fourteen years.

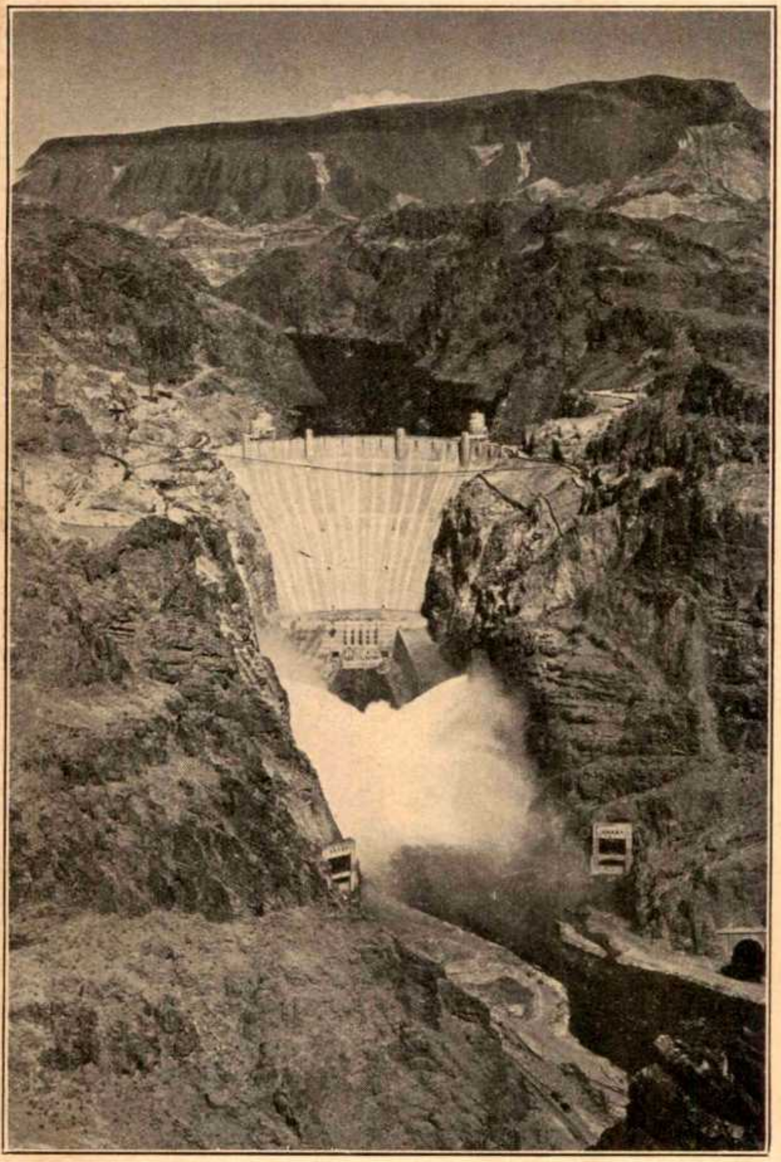

Fig. 1.
VIEW OF DOWNSTREAM FACE OF BOULDER DAM; IN THE DISTANCE IS FORTIFICATION MOUNTAIN.

As regards the potential developments, estimated on the basis of ordinary minimum flow and an efficiency of 70 per cent in installation, the following brief summary of continental aggregates is of interest: Europe, 58 million horse-power; Asia, 80 millions; Africa, 190 millions, of which no less than 125 millions is located in the basin of the Congo and adjacent territory; Oceanica, 17 millions; and America, 127 millions, of which 73 millions is in the northern hemisphere, and 54 millions in the southern.

Developed horse-power at the present time is spread over the world in the following approximate amounts: Europe, 24,300,000; Asia, 4,900,000; Africa, 115,000; Oceanica, 550,000; North America, 24,400,000, and South America, 1,000,000. In comparing these figures with those for potential exploitation, allowance must be made for the fact that the former are based on the actual capacity of the machinery installed, which averages from two to three times the potential power at low flow at the same sites.

A notable fact from the statistics is that Europe has practically caught up with North America in the capacity of actual installations. As against this must be set the fact that the unit magnitudes of certain installations in hand in the United States far exceed those of any other installation under construction in the world. Four outstanding examples may be mentioned: the Boulder Dam, on the Colorado River on the joint boundary of the States of Nevada and Arizona; the Norris Dam, on the Clinch River in North-Eastern Tennessee; the Bonneville Dam, on the Columbia River, at Bonneville, Oregon, and the Grand Coulee Dam, also in the Columbia Basin, but in the State of Washington. These undertakings are of such striking magnitude as to claim some detailed notice. The following descriptions are compiled from information kindly supplied by the authorities concerned.

THE BOULDER DAM

The Boulder Dam, perhaps the most notable of the four, has already received a brief preliminary notice in this journal (NATURE, Feb. 9, 1935) just before its completion in May 1935*. It is by far the highest dam in the world, with a height of 726 ft. above bedrock foundation, as compared with 450 ft., the height of the Chambon Dam in France, which at present ranks second in altitude. The crest length is 1,282 ft., and the structure enables the water surface of the Colorado River to be raised 584 ft. It is located on the Arizona-Nevada State boundary line, in upper Black Canyon on the Colorado River, about 30 miles south-east of Las Vegas, Nev., and 80 miles north of Needles, Calif. The natural geological formation of the site is andesite breccia, hard and very durable.

The dam, the downstream face of which, as it appears from a mountain top on the Nevada side of the Black Canyon, is shown in full extent in Fig. 1, is of the arch-gravity type, and contains 3,255,000 cubic yards of concrete, weighing somewhat less than seven million tons. The artificial reservoir formed by the dam has a capacity of 30½ million acre feet: it is 115 miles long, with a superficial area of 146,500 acres, or 229 square miles, and the filling with water is taking a period of about three years to complete. The view (Fig. 1) shows twelve discharge outlets fully open, resulting in two great cascades with a fall 13 ft. more than the Niagara Falls.

The upstream face elevation above the level of an intermediate impounding stage in Lake Mead

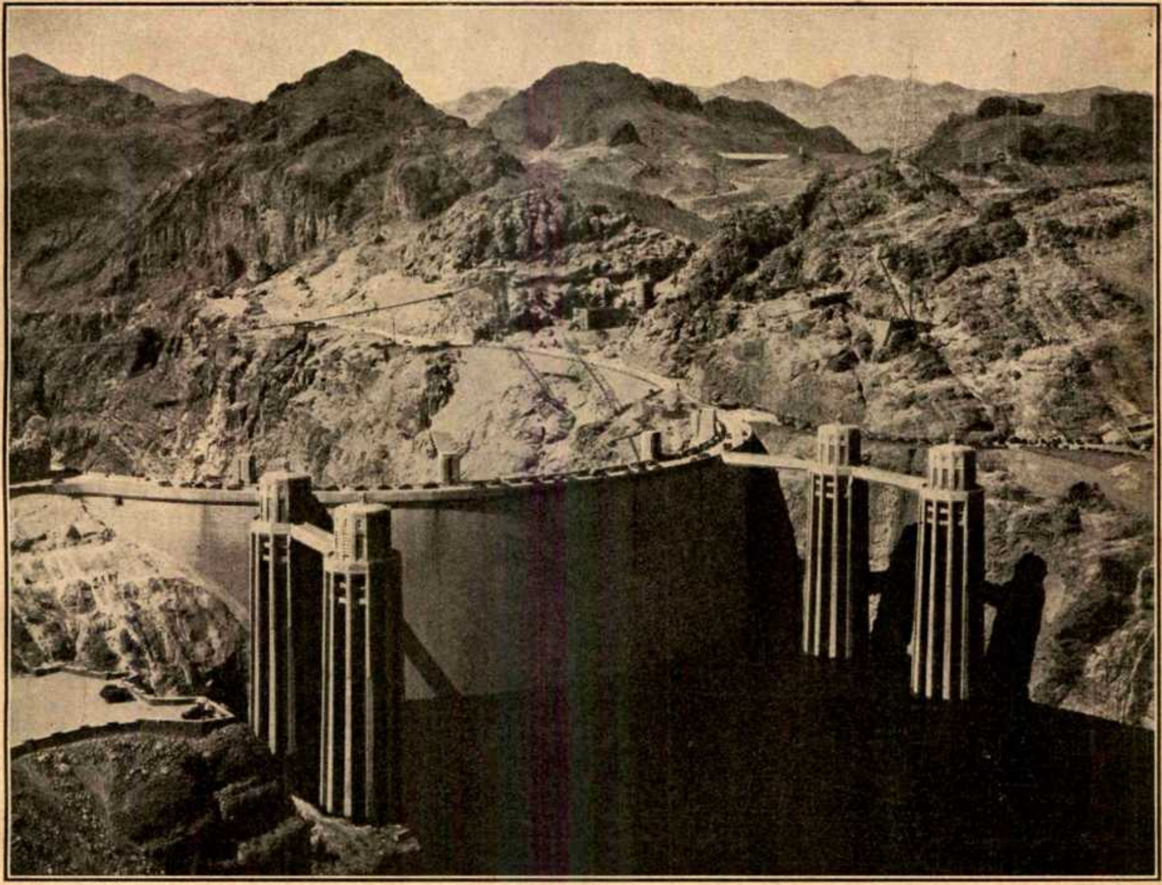

Fig. 2.
VIEW OF UPSTREAM FACE OF BOULDER DAM, SHOWING IMPOUNDED LAKE MEAD.

---

* It also formed the subject of a lecture delivered to the Institution of Civil Engineers on April 15 (*vide* NATURE, April 24, p. 706).

with a depth of more than 330 ft., is shown in Fig. 2. Motor-cars can be seen parked in the four-lane roadway across the dam. As will be seen, there are four reinforced-concrete towers located adjacent to the dam, two on each side of the river, and about 165 ft. apart in a direction parallel to the stream. The towers are 375 ft. in height, and average 75 ft. in diameter, decreasing from 82 ft. at the base to 63 ft. at the summit. Each tower controls a quarter of the water supply to the power plant turbines, to which they are connected by 30-ft. diameter plate-steel pipes installed in 37-ft. and 50-ft. diameter concrete-lined tunnels. Each tower has two cylindrical gate valves, 32 ft. in diameter and 10 ft. high, one near the bottom, and the other about mid-height.

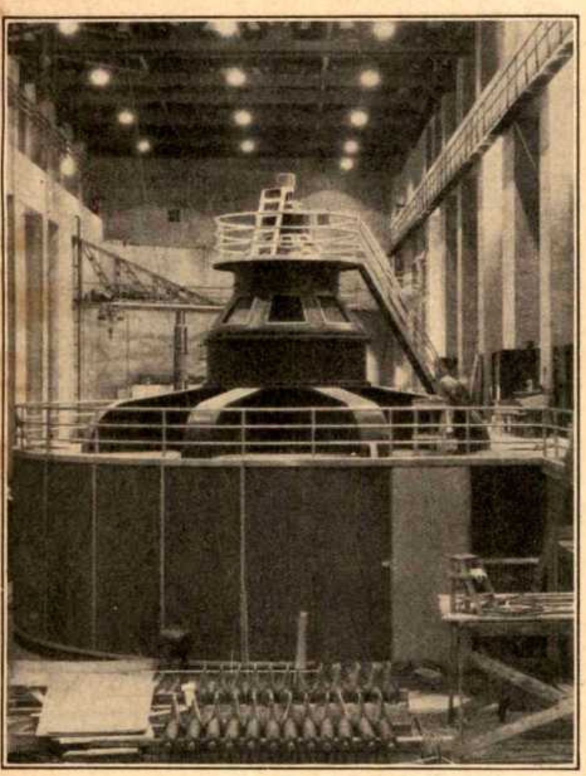

Fig. 3.

82,500 KILOVOLT-AMPERE GENERATOR IN BOULDER DAM POWER HOUSE.

Power development is contemplated to the extent of 1,835,000 rated horse-power. For comparison, it may be mentioned that the total horse-power at Niagara (United States) is 452,500, and at Dnieprostroy (U.S.S.R.) 750,000. A view of the power house is given in Fig. 1 above, and a view of the interior, showing one of the gigantic generators (capacity 82,500 kilovolt amperes) in operation since October 1936, is given in Fig. 3. Four 115,000 horse-power turbines are being installed at the outset, together with a fifth of 55,000 horse-power. The main plant units are unexcelled in magnitude in the world: they have a capacity nearly twice as great as any previously constructed—the nearest approaching them being the 83,000 h.p. turbines and the 76,500 kilovolt ampere generators at Dnieprostroy. The Boulder installation will be complete with fifteen large, and two smaller units about 1940, when about 663,000 horse-power will be continuously available, based on 83 per cent plant efficiency and 10 per cent maximum shortage.

The flow of the Lower Colorado River is an important feature of the project. The greatest measured discharge has been 240,000 cusecs (cubic feet per second) at Yuma, Arizona, but an abnormal flood is believed to have reached 300,000 cusecs for a short period in 1884. At the other end of the scale, the discharge has fallen to 66 cusecs, also measured at Yuma. At the site of the dam, the average discharge is 21,000 cusecs with an average annual run-off of 15,069,000 acre feet.

In addition to power generation, the water from the impounded area is to be used for irrigation purposes. Below the Boulder Canyon reservoir there are some 1,900,000 acres of irrigable land in the States of Arizona, California and Nevada, of which hitherto only 660,000 acres have been under irrigation. There is, therefore, abundant scope for further extensions of supplies of water for irrigation purposes.

Another feature of the project which should not be overlooked is the "All American" Canal, so called because it lies entirely in the United States, while the present Imperial Main Canal is largely in Mexico. The new canal will lead from the Colorado River to the Imperial and Coachella Valleys. The intake is at the Imperial diversion dam, at a site about 15 miles north-east of Yuma, Arizona. The length will be 80 miles to the Imperial Valley, and that of the main canal to the Coachella Valley, 130 miles. A maximum diversion of 15,000 cusecs of water is planned. The canal widths are 232 ft. at the surface and 160 ft. at the bottom, with 20·6 ft. depth. There are only two larger canals in the United States, both ship canals.

The Boulder Canyon Act authorized expenditure up to 165 million dollars (33 million pounds) on the project, of which 70 million dollars is the estimated cost of the dam and reservoir, 38 millions the cost of power development, and a similar sum the cost of the "All American" canal. Up to 1936 about 110 million dollars had been expended.

The photographs illustrating this article have been courteously supplied by the Bureau of Reclamation, Department of the Interior, Washington, D.C., U.S.A., as also, in conjunction with the U.S. Geological Survey, the information on which the article is based.

The Geological History of the Maidenhair Tree and its Allies

By Sir Albert Seward, F.R.S.

IT is probably true to say that *Ginkgo biloba*, the maidenhair tree, is the most interesting and impressive link with the past in the plant kingdom. Does it still exist as a wild tree? Most botanists would probably answer that far-travelled plant collectors in China have never seen a maidenhair tree growing under conditions in which man was not involved. It would, however, be rash definitely to assert that the question is settled. In 1933, a Chinese botanist, W. C. Cheng[1], after recording the occurrence of *Ginkgo* in certain localities in the Chekiang province, added: "This tree is very common in Tienmu-Shan, growing in association with coniferous and broad-leaved trees. It seems to grow spontaneously in that region." The word "seems" implies a lack of conviction. It may still be true to say that *Ginkgo* would have ceased to exist centuries ago had not man adopted it as an object of religious veneration and carefully tended it in the groves of temples and other favoured places.

This sacred tree is an isolated and primitive type; the solitary living representative of a comparatively large family distinguished by certain important peculiarities from other families of naked-seeded plants. About forty years ago, *Ginkgo* was removed from its former association with the yew among the Conifers and placed in a separate family, the Ginkgoaceæ, and even in a group of its own, the Ginkgoales. Ginkgoalean trees were formerly almost cosmopolitan; and there were many genera.

My present purpose is neither to follow through the ages the gradual rise into prominence of the Ginkgoales, nor to attempt a description of the wanderings of the several genera over the world's surface; it is simply to direct attention to some recent work which has greatly extended our knowledge of ginkgoalean trees in Arctic floras separated in time from the present by at least one hundred million years and more. It has long been known that *Ginkgo* and other members of the family were common trees in arctic lands, and flourished so far north as 80° N. lat. Professor Nathorst of Stockholm, writing in 1911, spoke of fossil leaves of a *Ginkgo* covering the surface of Lower Cretaceous shale in Spitsbergen as completely as the leaves cover the soil beneath a living *Gingko* tree in autumn.

The first contribution to be briefly considered is by Dr. Rudolf Florin of Stockholm, the author of a well-illustrated paper entitled "Die fossilen Ginkgophyten von Franz-Joseph-Land nebst Erörterungen über vermeintliche Cordaitales Mesozoischen Alters"[2]. Some of Dr. Florin's conclusions, which are of minor importance and do not affect the soundness of the work as a whole, may be questioned; but all botanists who regard the past history of recent genera as worthy of attention will heartily welcome this very valuable contribution from a leading expert in a special branch of palæobotanical research.

We are concerned only with the Ginkgoales. Improvement in methods of examining fossil leaves microscopically has greatly facilitated the discovery of more trustworthy evidence of natural affinity. It is seldom possible to cut microtome sections of petrified leaves or other plant remains, but Dr. Florin has succeeded in doing this with some of the Franz-Josef Land material after treatment with hydrofluoric acid. Petrified plants are relatively rare, and most fossil leaves occur as thin carbonized films on the surface of shale and sandstone. By the employment of a suitable technique, Florin and other palæobotanists have made substantial additions to a more exact knowledge of the histological structure of epidermal layers, which throws welcome light on relationship to recent plants.

Dr. Florin's paper is mainly devoted to an intensive and comparative study of ginkgoalean leaves from rocks of Lower Cretaceous age, approximately contemporaneous with the Wealden beds of south-eastern England. In 1880, Mr. Leigh Smith collected a few fossil plants in Franz-Josef Land: a larger collection was brought to England in 1896 in the steamship *Windward* chartered by the Jackson-Harmsworth Expedition. The plants were partially described in 1897 by Messrs. E. T. Newton and J. J. H. Teall: specimens collected by Dr. Nansen were described by Prof. Nathorst, and others by Graf zu Solms-Laubach. These descriptions have now been revised and greatly supplemented by Florin. The best material was found on the southern coast of the archipelago, where horizontal layers of basaltic lava, thickly covered with ice, overlie a few hundred feet of sedimentary rocks. These early Cretaceous plants afford a striking contrast to the few flowering plants, barely thirty in number, which are now able to withstand the long arctic night. There were trees in those days, and a flora clearly demanding much more genial climatic conditions.

The genus *Ginkgo* was represented by two, possibly more, species: *Ginkgo polaris*, originally described by Nathorst, with small semicircular leaves about 3·5 cm. broad and 2·5 cm. long, more or less deeply dissected into linear or wedge-shaped segments comparable on a smaller scale to the lobed leaves of the maidenhair tree borne on young shoots and seedlings. In venation and in the minute structure of the stomata and other epidermal cells, the arctic leaves closely resemble those of *Ginkgo biloba*. Another closely allied species is *G. coriacea* Florin. Some seeds from the same beds revealed epidermal characters similar to those of the leaves. The most important part of Florin's paper is the description of other genera of the *Ginkgo* family differing from the maidenhair tree in bearing long and narrow leaves in tufts on very short, deciduous branches surrounded at the base by a few persistent bud-scales (Fig. 1). These deciduous leafy shoots may be compared superficially with the so-called dwarf shoots or foliage-spurs of pines with two, three or five needles: in the ginkgoalean trees the leaves were usually broader and flatter, and more of them on each dwarf shoot.

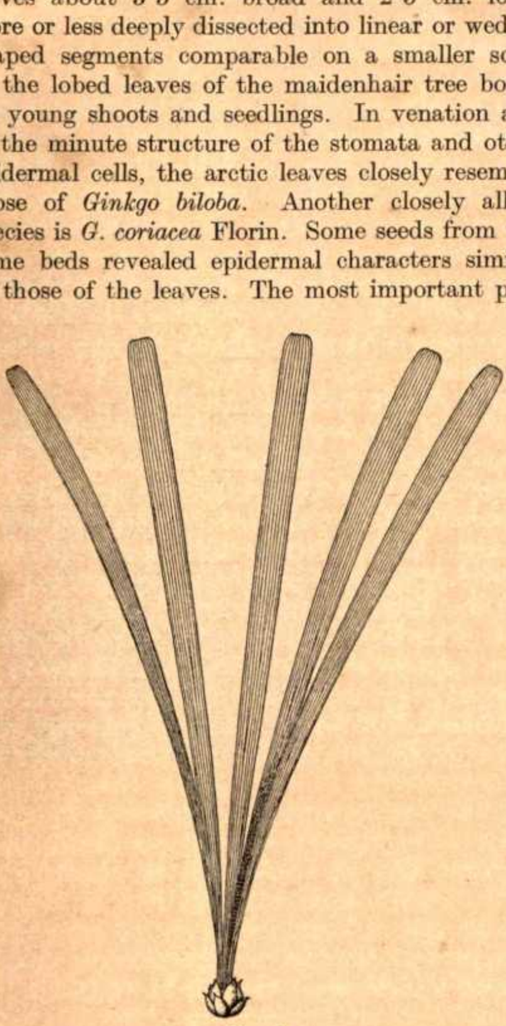

Fig. 1.

Windwardia Crookallii Florin. Reconstruction of a single dwarf shoot. ¾ nat. size. After R. Florin.

For the last sixty years, the name *Phœnicopsis* has been widely adopted for specimens of flat, linear, multi-veined leaves borne on very short shoots, or preserved singly. The generic name denotes a certain external form and venation, not a particular anatomical structure. Florin has now been able to assign certain distinctive types of leaves having the external form of species of *Phœnicopsis* to genera founded on anatomical character. One of these genera is *Stephenophyllum*, called after Cape Stephen on the south coast of Franz-Josef Land, where the best material was found. Seven leaves are borne on a diminutive axis surrounded by small, persistent bud-scales: such a shoot is comparable to the short branches of *Ginkgo biloba*, but differs in being much shorter and deciduous. *Stephenophyllum* is assigned to the *Ginkgo* family on the ground of similarity in certain important anatomical characters of diagnostic value. Another genus is *Culgoweria*, named after Culgower in Sutherland, a locality from which some linear leaves of the same form were originally described as a species of *Phœnicopsis*. This genus closely resembles *Stephenophyllum* in habit, but is distinguished by anatomical characters. A third genus, *Windwardia* (Fig. 1), differs from the other two in the absence of secretory ducts and in certain anatomical features. There are five leaves on each dwarf shoot. Among other new genera are *Sphenobaiera* and *Arctobaiera*, represented by leaves having the external form of the old genus *Baiera*, a name used for deeply dissected leaves, in some instances resembling the foliage of *Ginkgo* in outline, but with narrower lobes and without a leaf-stalk. In *Arctobaiera* the leaves were borne in tufts; some of them are divided in the distal portion into two narrow lobes. The genus *Sphenobaiera*, founded on a piece of leaf with tissues excellently preserved, differs in the greater degree of lobing and in anatomical characters. Another genus represented in the arctic flora is *Czekanowskia*, a world-wide type, characterized by still narrower leaves once or twice deeply forked, borne in bunches on a dwarf shoot.

The important point is that Florin has demonstrated by his skilful handling of the material that the ginkgoalean group was represented by at least six genera in the Wealden flora of Franz-Josef Land. As Dr. Florin says, the genera "show clear affinities to *Ginkgo*, whereas they exhibit such great morphological and anatomical differences in comparison with other recent and fossil gymnosperm groups that no near relationship with them can be assumed".

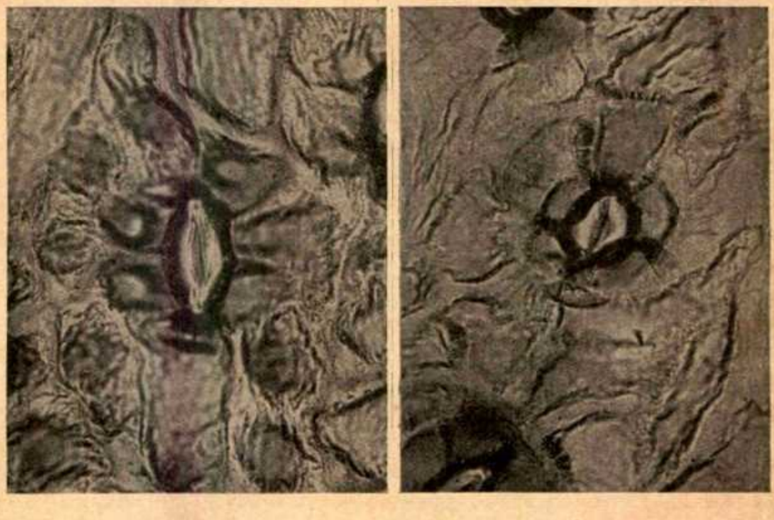
Additional evidence of the former abundance and variety of trees of the *Ginkgo* family in arctic floras has been furnished by Prof. T. M. Harris of Reading in a series of remarkable papers, published in the *Meddelelser om Grønland* during the last ten years, on the Rhætic flora of Scoresby Sound on the east coast of Greenland (lat. 70° 25′ N.). This exceptionally rich flora affords a most impressive example of the problem of climatic conditions raised by arctic fossil plants. Prof. Harris has been able to distinguish many species of *Ginkgo* (or *Ginkgoites*) by an examination of the epidermal structure of the leaves. He has also described species of *Czekanowskia, Baiera, Phœnicopsis,* and *Torellia,* a ginkgoalean genus previously recorded from Grinnell Land, still farther north; together with a new generic type which he has named *Hartzia.*

It is noteworthy that several species of these different members of the Ginkgoales recorded from Mesozoic floras north of the Arctic Circle are either identical with or closely allied to species previously described from Europe and the Far East.

The genera already mentioned do not exhaust the list of ginkgoalean trees discovered in Mesozoic floras of the world: we are concerned only with arctic forms.

The two photographs, Fig. 2 (*a*) and (*b*), for which I am indebted to Dr. Florin, illustrate the striking similarity in the stomatal apparatus of a fossil leaf and a leaf of the existing species. In both preparations of the epidermal film there is the same general arrangement of subsidiary cells encircling the stomatal pore. The thick black bands mark the position of strongly cuticularized cell walls. Fig. 2 (*a*) shows the epidermal structure of a leaf of *Ginkgo adiantoides* from Upper Tertiary beds (Pliocene) near Frankfort-on-Main: Fig. 2 (*b*) is from a leaf of *Ginkgo biloba*. The Frankfort leaves and others recorded from Pliocene beds in the Rhone Valley prove the existence of *Ginkgo* in Europe so late as the latter part of the Tertiary period shortly before the beginning of the Great Ice Age. We know that *Ginkgo* was a member of an early Tertiary (Eocene) flora on the basaltic plateau of which the Island of Mull is a detached fragment. The *Ginkgo* leaves from Mull in the Starkie Gardner collection in the British Museum (Natural History) are exceptionally beautiful examples of fossil foliage.

We cannot say with certainty when the *Ginkgo* family first appeared in the vegetation of the world; there is, however, some evidence of its existence as early as the Permian period. We know that it had reached an advanced stage of development before the end of the Triassic period in both the northern and the southern hemisphere. The family continued to occupy a prominent position almost throughout the world in the Jurassic and in the early part of the Cretaceous period. The genus *Ginkgo* persisted as a widely distributed tree well into the Tertiary era.



(*a*) (*b*)

Fig. 2.

STOMA AND ADJACENT CELLS ON THE LOWER SURFACE OF A LEAF OF (*a*) *Ginkgo adiantoides* (UNGER) HEER; (*b*) *Ginkgo biloba* L. × 400. AFTER R. FLORIN.

This brief account may serve to give point to Darwin's description of the maidenhair tree as "a living fossil", and especially to emphasize the fact that this sacred tree is the solitary living representative of a large company of genera which played a conspicuous part in the vegetation of the world through successive geological periods.

The Nottingham Meeting of the British Association

THE preliminary programme of the British Association meeting at Nottingham has been issued, and is obtainable from the offices of the Association at Burlington House, London, and at Commerce Chambers, Elite Building, Nottingham. The meeting will be held on September 1–8, and Sir Edward Poulton will be the president.

This will be the third time the Association has met in Nottingham. In 1866, the versatile Queen's Counsel and fellow of the Royal Society, William

R. Grove, presided over a meeting there, and in 1893 the president was Burdon Sanderson. On the first occasion, it was necessary to use 'the theatre' for the major meetings; on the second, the Albert Hall was available, and here again, next September, the presidential address will be given. In it, Sir Edward Poulton will review the history of evolutionary thought, as recorded in the meetings of the Association, a subject of very wide general interest, peculiarly appropriate to the Association which maintains Darwin's home as a national memorial, and fortunately chosen by one whose personal relations with the Association have been so intimate, over so long a period, as the president's.

For the rest, practically the whole of the meeting will find a new and very attractive venue in the University College. The old building in the centre of the city was in use in 1893, but now a fine new college occupies a beautiful and even inspiring site three miles from the centre, and here, or in the immediate vicinity, all the sections will meet, the reception room will be established, and many of the visiting members will be housed in the excellent hostels. Lest any who live or will be staying in the heart of the city should fear that the distance of the College will be a drawback, it should be stated that ample means of conveyance will be arranged, and that the city authorities are making generous provision for the free transport of visiting members. The convenience of concentrating so much of the business at a single centre is manifest.

The first evening discourse will be given by Dr. R. E. Slade on the suggestive subject of grass and the national food supply, and the second—arranged too late to be included in the preliminary programme—by Prof. J. Gray, who will deal with the movements of fish. The provision of lectures to the public, which the Association always undertakes if asked to do so, has found a wide welcome, for such lectures have been asked for, and will be given, in Nottingham itself (by Prof. H. Hartridge, on illusions of colour) and in Derby, Lincoln, Long Eaton, Mansfield, and Newark.

The sections already announce a number of principal items in their programmes, of both general and special interest. The full list is too long to detail, but reference may be made to the unusual feature of six sections (Geography, Geology, Zoology, Botany, Agriculture, and Economics) contributing to an evening discussion on planning the land of Britain. An extensive series of excursions and visits is planned. Nottingham itself is a centre of unusually varied scientific interest, in respect of its manifold industrial and historical features, and it commands a district, from Derbyshire on one hand to Lincolnshire on the other, possessing a scenic and economic variety remarkable even in England. A civic reception will be given in Nottingham Castle, and a garden party at the University College.

Occasion is taken to announce in this preliminary programme certain matters not relating to the annual meeting, among them the new activity of the Association in arranging the Alexander Pedler and Norman Lockyer lectures, taken over from the British Science Guild since that institution was incorporated into the Association. The Pedler lecture will be given by Prof. Allan Ferguson in Leicester, in co-operation with the University College in that city, on Monday, May 3, at 8 p.m. The Norman Lockyer lecture will be given in the Goldsmiths' Hall, Foster Lane, London, by kind permission of the Goldsmiths' Company, on Wednesday, November 24, by Dr. R. E. Mortimer Wheeler.

Obituary Notices

Prof. D. A. Low

To Prof. David Allan Low, emeritus professor of engineering, East London College, University of London, who died on March 24, a host of distinguished engineers, and architects and chemists scattered throughout the Empire are a living memorial. Few men in fact have had greater influence on the technical education of Great Britain by his lectures and by his text-books. Probably the most successful writer of engineering text-books who ever lived, his influence has extended to every university and technical college throughout the English-speaking world.

Prof. Low was extraordinarily patient, rarely angered, amazingly thorough, great beyond words in his efforts to help his friends, a man to whom a man could anchor his affections and loyalty, a man whom it was a privilege to serve, a great engineer. He never said a word against anyone. Perhaps his greatest characteristics were his extraordinary thoroughness and imperturbability. Was not the great success of his students in after-life are flection of these characteristics?

On his seventieth birthday, a banquet and presentation was held in his honour by a large number of old students, and on February 9 last—his eightieth birthday—some of his intimates dined together at the "Cheshire Cheese". It was one of those simple, informal, unforgettable occasions, with everyone in perfect harmony inspired by an abiding affection.

The quality of those men and the affectionate intimate speeches were an ample testimonial of the worth of "Daddy Low".

Prof. Low's early general education was received at the High School and West End Academy, Dundee. During apprenticeship, he attended evening classes for science and technical subjects and afterwards studied at Owens College, Manchester, and the University of Glasgow. Altogether he spent seven years in engineering workshops and drawing offices before taking up a lectureship in engineering at Allan Glen's Institution, Glasgow. He was headmaster of the Day Technical School for Boys at the People's Palace, London, a school which set a high standard to technical education never surpassed. For twenty-six years he was professor of engineering in East London College, University of London.

Many very successful text-books stand to Prof. Low's credit, dealing with machine drawing and design, practical geometry and graphics, engines and other engineering topics. Most of these books, which are singularly free from mistakes, have seen many reprints. His "Heat Engines" took about five years to write. He loved his book writing and was never satisfied until he had everything as perfect as he could make it. As the result of this meticulous care, most of his books are as good to-day as when they were written.

For many years, Prof. Low was greatly interested in the theatre and opera, went to many 'first nights' and particularly to his favourite place of entertainment, the "Old Vic". He was very fond of travel, went to Canada and the United States four or five times, the last time being in 1932 with the Institution of Mechanical Engineers, of which he was one of the oldest members. Since his retirement he made eight or nine trips in the Mediterranean with his wife, and did a good deal of motoring with two devoted daughters.

On his last day, Prof. Low smoked two cigars—his great luxury, the gift of his old students—went to bed in the library where his books were written. At 11.30 p.m. he was sleeping peacefully, at 12.30 a.m. he had ceased to sleep. To Mrs. Low and her family his old students unite in deepest sympathy. They will never cease to hold him in grateful memory and abiding affection. He will ever remain an inspiring example to British engineers.

Mr. Adolf Gallenkamp

ADOLF GALLENKAMP, whose death at the age of eighty-eight years occurred on February 26, founded the firm which bears his name about fifty years ago. He was a shrewd observer, and foresaw that a wider recognition of science in academic and industrial circles in Great Britain was inevitable. In conformity with this view, he devoted the early part of his business career to the provision of apparatus for schools, of a better and more varied type than that previously in use. The success achieved in this direction led him to extend his work to higher educational institutions, and he found a special field in the technical colleges and polytechnics which were being established in different parts of the country. Later, he extended his activities to the special requirements of industrial laboratories and the medical and other professions, and always strove to provide the latest and best types of apparatus.

Mr. Gallenkamp frequently visited laboratories in other countries in search of new ideas, and always welcomed suggestions from those who had dealings with him. He was a diligent reader of scientific publications, from which he frequently extracted information which enabled him to improve on many of the instruments then in use. His time was so completely occupied in his business that he was unable to take an active part in the work of scientific bodies in London, and few to whom the name of his firm was well known were personally acquainted with this genial and gifted man, whose face bore a striking resemblance to that of Victor Hugo. He gathered round him a staff of competent men who shared his enthusiasms, and had the satisfaction of seeing his business grow from a very humble beginning to one with a world-wide connexion.

All scientific men recognize the debt they owe to those who provide the instruments upon which the quality and quantity of their work so largely depend, and amongst the many who have contributed in this way to the advancement of science, the name of Adolf Gallenkamp will be honoured by all those who knew or had dealings with him. C. R. D.

WE regret to announce the following deaths:

Dr. Katharine J. Bush, formerly of the Zoological Department of the Peabody Museum, Yale, known for her work on annelids, molluscs, and other marine invertebrates, on January 19, aged eighty-one years.

Prof. H. Bechhold, director of the Institute for Research in Colloid Chemistry at Frankfort-on-Main, known for his work on colloids in biology, on February 18.

Mr. J. W. Capstick, fellow of Trinity College, Cambridge, on April 27, aged seventy-eight years.

Dr. A. H. Church, F.R.S., formerly University lecturer in botany, Oxford, on April 24, aged seventy-two years.

Dr. Milton J. Greenman, director of the Wistar Institute of Anatomy, Philadelphia, an authority on the nervous system, on April 7, aged seventy years.

Major J. Herschel Hardcastle, an authority on small arm ballistics, on April 21, aged sixty-six years.

Dr. T. G. Macaulay Hine, O.B.E., known for his work on pathology, especially cerebrospinal fever, on April 25, aged sixty-six years.

Prof. Enrique Paschen, formerly director of the Vaccination Institute of Hamburg, an authority on smallpox and vaccination, aged seventy-five years.

Prof. Julius O. Stieglitz, professor of chemistry in the University of Chicago, known for his work in organic chemistry, on January 10, aged sixty-nine years.

Prof. W. M. Wheeler, professor of entomology in Harvard University, on April 19, aged seventy-two years.

News and Views

Prof. T. G. B. Osborn

THE Sherardian chair of botany in the University of Oxford has been filled by the appointment of Prof. T. G. B. Osborn, at present professor of botany in the University of Sydney. Prof. Osborn graduated in 1908 in the University of Manchester with first-class honours. His exceptional abilities were recognized by his immediate appointment to a lectureship in economic botany in Manchester which he held until 1912, when he was elected professor of botany, vegetable pathology and parasitology in the University of Adelaide. The excellence of his teaching and the energy with which he threw himself into his academic work is attested by the fact that when he left Adelaide in 1927, large and commodious laboratories had been built as well as an experimental greenhouse. While in Adelaide, Osborn acted as consulting botanist to the Government of South Australia and in furtherance of the pastoral interests of the country he established a field laboratory at Koonamore, some two hundred miles north of Adelaide, where he and his assistants could study the vegetation of an arid region and make useful suggestions to the grazing interests. Certain pastoralists interested in this ecological work which Prof. Osborn was carrying on presented an area of 1,200 acres to the University to extend these investigations.

IN 1927, Prof. Osborn was appointed to the vacant professorship in Sydney, and here, too, the number of the botanical students soon increased and necessitated laboratory and greenhouse extension. In addition to his academic work, Osborn was asked by the Commonwealth Council for Scientific and Industrial Research to review the botanical work in progress in the various universities and other research institutes in Australia, and in 1927 he was appointed adviser to the Council and was offered the directorship of the Division of Plant Industry; but he preferred to continue to devote himself to teaching and research. As an investigator, Osborn, in spite of his heavy teaching and administrative work, has been continuously active. His earlier published researches dealt with mycology and morphology, but since he has been in Australia he has devoted himself largely to ecological work. Not only has he made valuable contributions to the ecology of the arid regions of South Australia, but also more recently he has devoted some attention to forest problems in New South Wales, and journeys in Australia and elsewhere have given him a wide outlook on ecological problems. Since the Biology Board at Oxford has indicated that an ecologist would be most suitable for the Sherardian chair, the selection of Prof. Osborn would seem a most suitable one.

Dr. John Louis Tiarks, F.R.S. (1789-1837)

THE report of the council of the Royal Astronomical Society read at the eighteenth annual general meeting contained an appreciation of the services rendered by Dr. John Louis Tiarks, who died on May 1, 1837, at Jever, Germany, his native town. Born in May, 1789, Tiarks had been educated at the University of Göttingen and in 1810 came to England, and was given a post in the library of Sir Joseph Banks. His knowledge of mathematics and astronomy led to his being appointed British astronomer to the commission appointed under the Treaty of Ghent of 1814 to settle the American Boundary Line, the United States at the same time appointing Ferdinand Rudolph Hassler (1770–1843) as their representative. The survey of contested points was carried out, but certain matters were referred to the King of the Netherlands for decision. His views, however, did not prove acceptable to the United States, and even in 1838 an extent of 10,000 square miles remained disputed territory. On his return to England, Tiarks was entrusted by the Admiralty with several important scientific missions. In 1822 he determined the position of Funchal by means of fifteen chronometers sent from Greenwich to Madeira. He afterwards made observations at Dover, Falmouth and Portsmouth, bringing to light errors in the trigonometrical survey. In 1825 he made other observations in the North Sea in H.M. Steam Vessel *Comet*, on which occasion Sir Humphry Davy accompanied him in order to make observations on the compass. He left Great Britain in March 1835, and in the spring of 1836 was struck down by paralysis from which he never recovered.

Regulations for German Scholars Travelling Abroad

THE following is a translation of an extract from a decree of the German Minister of Education entitled "Foreign Travel by University Teachers and Students" and dated December 24, 1936, recently received at NATURE office: "It has frequently been observed of late that Germans and especially professors and students, when travelling abroad for cultural or scientific purposes, have failed to establish contact with their local national official representatives. Such contact is specially important in countries where Jews occupy a predominant influence in cultural affairs, and where emigrants seek to press into the foreground in questions concerning German cultural life. In these countries it is particularly necessary that German national guests, local or official, shall be informed of these local relationships by the official national representatives abroad. I therefore order that all under control of my Ministry who travel abroad for study, research or lectures, or for congresses or similar purposes, shall on their arrival in a foreign country forthwith get into contact with the competent local representative of Germany, with the Foreign Organization of the Nazi Party and with the branch office of the German Academic Exchange Service, whenever possible. If this be not done, a short report of the reasons must be furnished to me. I take this opportunity to point out that previous decrees concerning foreign journeys are still not always obeyed by all concerned. For example, news of a proposed journey abroad by persons under control of my Office often reaches me first through the German Centre for Congresses. This results in delay, and the person involved not only risks refusal of the necessary foreign exchange, but is also acting in defiance of my orders. I therefore hereby order all controlled by my Office to obey in every detail the Decree on Foreign Travel, and to lay before me, through the official channels, any applications for permission to travel abroad."

German Refugees at the University of Istanbul

MANY former members of staffs of German universities and other institutes have, as is now well known, either been forced to leave or have voluntarily vacated their posts, for political, racial and other reasons. Some have obtained analogous posts in the universities of countries outside Germany, and we have recently received a list of those who are now working at the University of Istanbul. Among these are Prof. H. Winsterstein (physiology), Prof. M. Brauner (botany), Prof. M. Dember (physicist), Prof. M. von Mieses (mathematics), and nearly thirty others, most of whom have been appointed to chairs in the University of Istanbul. Prof. M. Freundlich, who is at present professor of astronomy, leaves at the end of the academic year for the University of Prague, and Prof. F. Dessauer, professor of rontgenology, is going to the University of Fribourg, Switzerland.

Broadcasting and the Coronation

CORONATION day, May 12, is likely to mark an interesting and notable event in the history of radio communication, for it will witness the most complicated outside broadcasts yet undertaken by the British Broadcasting Corporation. The arrangements for the sound programme were explained in the issue of the *Radio Times* of April 23, while some details of the means to be adopted for televising the Coronation procession were given in *World Radio* of the same date. On the sound side, apart from the arrangements necessary for the home and Empire programmes, the B.B.C. is providing facilities for about a dozen foreign observers to broadcast commentaries in their own languages direct to their own countries. Two separate control rooms will be established, one at Westminster Abbey for the British programmes and the other at the Middlesex Guildhall for the foreign commentaries. In addition to supplying all the B.B.C. transmitters, the 'home' programme will be distributed to loudspeakers within the Abbey and to others on some of the stands along the route followed by the procession. By this means, a large number of the public will be enabled to follow the progress of the procession and to hear the service in the Abbey. At the foreign control room, provision is being made for ten separate commentaries in different languages to be fed by land-line to the International Trunk Exchange of the British Post Office, whence the programmes will be distributed to the countries concerned. Some 472 miles of special wiring are involved in the whole installation, which is being carried out by the General Post Office in co-operation with the B.B.C. Engineering Division. This one outside broadcast will involve the use of fifty-eight microphones, and, not least among the technical difficulties, is the necessity of rendering the installation of these as inconspicuous as possible, particularly inside the Abbey.

ON the television side, May 12 will go down in history as the first day on which the direct television of a remotely controlled outside programme has been attempted from the London ultra-short-wave station. For this purpose, the Post Office has installed a special co-axial cable, connecting the Alexandra Palace transmitter with Broadcasting House and the observation point at Hyde Park Corner. In addition, and as a stand-by service, the B.B.C. will use a van equipped with an ultra-short-wave transmitter for feeding the programme to Alexandra Palace. The observation point at Apsley Gate, Hyde Park Corner, was selected on account of its having a combination of several advantages. The afternoon sun had to be behind the 'cameras' and preferably on the objects to be televised; on account of the small receiver screen, the site must allow close-up views on a level with the windows of the royal coach; at the same time, the site must permit an extensive view of the procession as a whole; finally, and not least important, the apparatus must be remote from the huge crowd of the general public. At this site, three 'cameras' will be used for converting the visible scene into the high-frequency electrical currents to be passed along the cable: one of these 'cameras' will be near the main arch at a height of five feet above the pavement; the second will be about ten feet above ground-level and will be used for viewing the crowd and the approach of the procession to within a few yards; the third will be on the other side of the arch and used for following the procession as it disappears towards Constitution Hill. A separate circuit with microphone will be used for providing the sound commentary to this programme. Much of the apparatus to be used on this occasion will be new and untried except on an experimental basis, while very special conditions will prevail on Coronation day itself. The occasion will, however, most decidedly mark the beginning of a new era in television.

British-American Understanding

SIR FREDERICK WHYTE presided over a discussion, held on March 4 under the auspices of the English-Speaking Union, on "The Contribution of British Schools, Universities and other Educational Bodies to British-American Understanding". The discussion was opened by Mr. J. Wickham Murray, who outlined some of the work of the Union in developing contacts between Britain and America. He specially stressed schemes such as the Page Scholarships scheme for men and women teachers, reciprocal scholarships under American direction, exchange of school boys and school masters and mistresses, and assistance given to visitors in both countries. He indicated, however, that the Union desires now to widen its work and to face the greater responsibilities which the present state of the world suggests it should undertake. To that end it has formed a Research and Discussion Committee, which is seeking the advice and guidance of experts in such fields as foreign affairs, economics, the Press of both countries, and general relationships such as would arise as a result of neutrality legislation and American grievances against British policy. Already meetings of experts in these matters have been held, and, at every meeting, the importance of closer attention to matters of education has been stressed.

MR. WICKHAM MURRAY added that, in thinking it important for British students at school and university to get an accurate picture of English-speaking countries, the Union believes that because of similarities in our joint democratic institutions, experiments in those countries might be of greater relevance to Britain than experiments in such very different countries as Soviet Russia, Italy or Germany. In asking the meeting to consider what might be done to improve the contribution of British educational bodies so far as an understanding of problems in English-speaking countries is concerned, he raised the question of possible changes in examination syllabuses, special facilities for providing books on American and Dominion history and affairs, the increase of scholarships and fellowships, and the introduction of special courses on the subject into curricula.

MR. H. G. WELLS, president-elect of Section L (Education) of the British Association, who contributed to the discussion, thought there will be no peace in the world until education has been recast into a common basis of understanding throughout the world. He had little confidence in what has been called 'scientific' American, British, or other history. There is but one history—the history of mankind. The world is involved in great issues of human ecology and of economics, but little of these things is taught. He said that we shall have to realize—and it will be a wrench—that much of the history at present taught is stale, unprofitable and out of date. British people are curious about America. They devour American publications; they patronize American films; they are learning to think and speak American; but they are not interested in the history of the Constitution or local points of pre-Civil War days. The public is willing to react against limited histories and get into general understandings, but the schools hold up this natural development towards the human understanding of the world.

The National Maritime Museum

THE National Maritime Museum, opened by H.M. the King on April 27, is a notable addition to the public galleries of Great Britain. Housed in a building with historic associations from which can be seen on one side Greenwich Park and the Royal Observatory and on the other the Royal Naval College and the Thames, the Museum will make an appeal to all who take an interest in the history of naval affairs, the growth of the British Empire and the lives of great British seamen of the sixteenth, seventeenth and eighteenth century. It has come into existence through the enthusiasm of the members of the Nautical Research Society, the munificence of Sir James Caird and finally the passing of the National Maritime Museum Act of 1934. The buildings it occupies include the Queen's House finished three hundred years ago, and the wings erected during the nineteenth century when the place was used for the Greenwich Hospital School, now removed to Holbrook, Suffolk. After restoration by the Office of Works, both the Queen's House and the other buildings have been turned into galleries, which now contain the most magnificent series of sea pictures in existence. In addition to the portraits, seascapes, and battle scenes, the great Macpherson collection of prints, drawings, etc., there are beautiful models of ships of the various periods, collections of navigational instruments and a spacious library. No attempt so far has been made to illustrate the great revolution in maritime affairs during the nineteenth century or the historic events of more recent times, but these no doubt will be taken into consideration in due course. The thanks of the whole community, no less than those of students of maritime affairs and of marine art, are due to Sir James Caird, who has made the nation his debtor by the support he has given to the formation of the museum.

The Newcomen Society

ON April 21, simultaneous meetings of the Newcomen Society took place in London and New York, when two papers were read. The first of these was by Dr. A. Raistrick, and was entitled "The Steam Engine on Tyne Side, 1715–1778" and the second was by Prof. J. W. Roe on "Interchangeable Manufacture". Dr. Raistrick's paper was based on the records preserved by the North of England Institute of Mining Engineers, Newcastle-upon-Tyne; these records consisting largely of "View books" compiled by the colliery 'viewers', the forerunners of the present-day mining engineers. The reports of the 'viewers' contain much information as to the flooding in the mines and the cost of the engines and the pumping. By means of the various papers, Dr. Raistrick has been able to trace the erection of no fewer than 104 'fire engines' built between 1733 and 1778, before the improved engines of Boulton and Watt came on the scene. A rough figure for the first cost of an engine with a 33 in. cylinder was about £1,200 and the annual cost of working it £400. Though 13 engines were built between 1715 and 1733, all of the Newcomen type, it has been impossible to trace any connexion with them of Newcomen or of the "Proprietors of the Invention for Raising Water by Fire" who had exploited the engine. The paper was accompanied by a valuable map of the coal field showing the sites of the engines. In Prof. Roe's paper it was shown that interchangeable manufacture had begun with firearms early in the nineteenth century and had afterwards spread to clocks, watches, sewing machines, bicycles and motor-cars. Of all the products of modern industry, the motor-car has pushed interchangeable manufacture furthest, and to the benefit of the widest public.

Low Temperature Carbonization Plant

THE recent opening by the Duke of Kent of a new plant erected near Chesterfield by Messrs. Low Temperature Carbonisation Ltd. has once again directed public attention to the commercial possibilities of carbonizing coal at comparatively low temperatures (about 600° C.). This method of treating coal has as its main product a smokeless fuel which can readily be burned in any open grate, and in consequence is a valuable contribution towards a solution of the important problem of reducing atmospheric pollution. In addition, the process yields as by-product a tar from part of which a fuel suitable for use in Diesel engines can be prepared and a motor spirit of high antiknock value. The tar is also amenable to treatment by hydrogenation for the production of further motor spirit if desired. In view of a possible national emergency, there is a tendency, particularly among those not acquainted with all the relevant details, to stress the value of low temperature carbonization as a source of home-produced motor spirit. It is, therefore, well to bear in mind that although any method of producing oil or spirit from coal is of national importance, the spirit is in this case only a by-product, and that even if all the tar were hydrogenated to produce additional motor spirit, the total yield would be extremely small when compared with the quantity now imported.

Centenary of the University of Athens

THE University of Athens is the richer to-day by the congratulations of the world of learning on its centenary. Elaborate celebrations have marked this event, which was enhanced by the active participation of H.M. the King of Greece, members of the Government, of the Church and of the Services, the French Minister of National Education, and 150 delegates representing eighty foreign universities. Eloquent addresses, official receptions, musical festivals and classical performances added to the splendour of the occasion. During the past hundred years, the University of Athens has grown from a small establishment with fourteen students, to a mighty seat of learning with nearly ten thousand students of both sexes, an imposing list of professors, and manifold extensions, laboratories and institutes as additions to the original faculties. Parallel with the development, learning has found in Athens the old spirit which made the town famous throughout the classical and Byzantine periods. To-day, science and letters are steadily pursued by a band of investigators who have made substantial contributions to knowledge. To give just one example, mathematicians are familiar with the names of Hatzidakis, Zervos, Sakellariou and Eginitis. Even the history of science is represented by Prof. Stephanidis, who has many important monographs to his credit. If the English language and literature were not hitherto adequately represented, the omission has been made good by the creation of a Byron chair, which was announced as a gift of Great Britain to the most ancient seat of learning of Western civilization.

Witchcraft in Bechuanaland

WIDESPREAD interest has been aroused by the trial for witchcraft of Bagakgametsi, the former wife of Tshekedi, son of Khama, and regent chief of the Bamangwato tribe. This chief, it will be remembered, earned notoriety a little while ago for inflicting punishment on a white man, as it was held, illegally, and was deprived of his chieftainship in consequence. In February 1936 he married his cousin, Bagakgametsi, but secured a divorce from her on March 7 of this year. She is now twenty-seven years old, and was described by Sergeant Lewis, the prosecutor in the present case at Serowe, as "an educated woman". With her were accused two men, who are described as witch-doctors. The offence alleged was "practising witchcraft calculated to injure the Queen-Mother, Semane"; but it was asserted in evidence, as reported, that Bagakgametsi herself was in fear, or stated that she was in fear of witchcraft by the Queen Mother, and consulted her two co-defendants to verify her suspicion and secure protection. One witch doctor in giving evidence in defence stated that he blew on a horn and threw the bones—the usual divinatory procedure in such cases—and said, "If Semane is bewitching Bagakgametsi she should die from blood". He added that Semane would die within two months. The other witch doctor said that the woman came to him for medicine and said she was afraid that Semane, who was jealous of her, would kill her. On the other hand, it was alleged by the prosecution that Bagakgametsi had asked one of the men for a poison root to get rid of the Queen Mother so that she alone should share Tshekedi's power. The verdict was "guilty", and a fine of £50, or twelve months imprisonment was imposed. The case is interesting as illustrating the strong hold of a belief in witchcraft on this people, even among the more enlightened, as well as the illogical working of the attempt to suppress the belief, which concentrates on the witch doctor, who though in many instances undoubtedly fraudulent, is at least working against an anti-social force which in such circumstances as these goes free. The British code, however, does not recognize witchcraft as such.

Synthesis of Large Molecules

AT the Friday evening discourse at the Royal Institution on April 23, Prof. H. Mark discussed "The

Synthesis of Large Molecules". In Nature, all organized objects consist of large molecules. The great importance of the natural highly polymerized substances has led to the conclusion that very valuable mechanical and physiological behaviour is associated with these macro-molecules. Therefore the industries concerned with synthetic rubber, artificial silk and synthetic resins have worked out a number of synthetic high polymers, which are, in fact, of great use in making insulators, fibres and solid materials of high resistance and valuable properties. It appears that the kinetics of polymerization reactions is very complicated, but one can already distinguish three main processes which play an important role in every polymerization reaction. First a nucleus of high reactivity must be built. This can be done by a thermal collision of high energy, or photochemically, or by means of a catalytic agent. The production of these nuclei requires a high activation energy, and is therefore rather slow. The nuclei react quickly with the molecules of the monomeric substance and grow with rather high velocity stepwise to a chain. The activation energy of the growing reaction is low (about 5,000 cal./mol.) and therefore the probability of the growth is large. The chains would grow infinitely if there were not break-up reactions of different kinds. There is the possibility that the growing of the chains may be ended by lack of monomeric substance; it is possible that the decreasing steric factor of the association reaction may diminish the velocity of chain growth to a very low rate, and one must consider that different side-reactions may break up the chains suddenly. In the case of styrene, we have succeeded in distinguishing these three different stages and developing a reaction mechanism which seems to be in fair agreement with the experimental data.

Recent Acquisitions at the Natural History Museum

AMONG recent additions to the Zoological Department at the British Museum (Natural History) is a specimen of the pigmy scalytail of West Africa received from the Basle Museum. The Department has also acquired a large number of small mammals and birds from Yugoslavia collected by Mr. V. Martino. This collection, comprising a number of new forms, is of considerable scientific importance and will help to fill one of the chief gaps in the study collections of mammals and birds. An important purchase for the Department of Entomology is the remainder of the Fruhstorfer collection of butterflies. 13,799 specimens, comprising the Lycænidæ and Hesperiidæ, were purchased by the Trustees in 1933, and a small section of the collection (the oriental Nymphalidæ) have in the interval been sold to the Paris Museum. The balance now acquired consists of 48,677 specimens, of which about 3,000 are the actual specimens upon which the original descriptions of the species were based. The Mineral Department has been given by Mr. J. D. Hague a specimen of native gold in beautiful bright crystals, from the North Star mine, California. Mr. Felix F. Wilson has presented a small collection of gold which has been picked up from burns at Leadhills, in Lanarkshire, by the late Mr. Thomas Newbiggin, who was for many years engaged in mining there. A magnificent, clear blue, step-cut, flawless blue topaz, 614 carats in weight, from Brazil has been bought. Owing to the easy cleavage of this mineral, it is seldom that a coloured stone of this size is so free from flaws.

Fourth International Grassland Congress

THE fourth International Grassland Congress is to be held in Great Britain on July 8–23 under the presidency of Prof. R. G. Stapledon. The paper-reading sessions will be held in Aberystwyth on July 14–18. Before and after these sessions, delegates will be shown the leading types of grassland in Great Britain, in a tour from Oxford to Aberystwyth and from Aberystwyth to Edinburgh. Fifteen plenary papers are to be presented to the Congress by delegates from Great Britain, Sweden, Germany, Italy, Finland, United States, Canada, Australia, New Zealand and South Africa. The remaining papers will be read to sectional meetings of the Congress, which will deal with the following aspects of the grassland problem: (1) grassland ecology, (2) seeds mixtures, (3) plant breeding and seed production, (4) fertilizers, (5) nutritive value and fodder conservation, and (6) pastures. Full details regarding plans for this Congress and a list of all papers to be presented are obtainable from the Joint Secretaries, Fourth International Grassland Congress, Aberystwyth. Particular attention is directed to the closing dates for receipt of applications (May 15 and June 19, according to the option selected).

The Parliamentary Science Committee

THE latest addition to the constituent bodies of the Parliamentary Science Committee is the British Institute of Radiology. For some time past the Committee has been engaged in investigating how the Patent Office Library could be brought up to date in such a manner as to serve the interests and convenience of the public who make use of that Library. The British Science Guild undertook a similar inquiry some years ago, and the Parliamentary Science Committee made its report the starting point for the investigation. A report has been completed, and the Parliamentary Science Committee has been in communication with the Chartered Institute of Patent Agents. Dr. Leslie Burgin, M.P. (Parliamentary Secretary of the Board of Trade), has now consented to receive a deputation from the Parliamentary Science Committee on the subject on May 3. The deputation will be introduced by Sir Arnold Wilson, the chairman of the Committee, and it will include two or three members of parliament who are also members of the Committee.

The Mellon Institute

THE new building of the Mellon Institute, Pittsburgh, will be dedicated on May 5–9. At the formal dedication of the building in the afternoon of May 6 in Carnegie Music Hall, with Dr. Weidlein presiding, addresses will be given by three Nobel prizemen, namely, Dr. Irving Langmuir (chemistry), Dr. H. C. Urey (physical chemistry), and Dr. W. P. Murphy (medicine). Brief addresses will also be given by Andrew W. Mellon and Richard K. Mellon, representing the founders. A symposium on "Recent Progress in Science" will be held on May 7. Speakers will include Dr. G. O. Curme, jun., Dr. F. B. Jewett, Sir Frederick Banting and Dr. W. W. G. Maclachlan. The new building, which has taken six years to complete, is to be dedicated to science and humanity in honour of Andrew W. and Richard B. Mellon, founders of the institution, who in 1911 gave support to the research fellowship system advanced by the late Robert Kennedy Duncan by establishing a specific department at the University of Pittsburgh, and in 1913 placed the system on a permanent basis with the organization of Mellon Institute.

Discharged Soldier Settlers in New Zealand

ACCORDING to the report of the New Zealand Department of Lands and Survey on Discharged Soldiers Settlement for the year ended March 31, 1936, a further twelve applications for land were received during the year, seven of which were granted, making a total of 4,093 allotments, covering 1,440,818 acres in the twenty-one years the Act has been in force. A grand total of 1,452,829 acres has been proclaimed for this purpose since the inception of the scheme. Loans authorized during the year numbered 719, involving an amount of £66,517. Reports from the District Commissioners of Crown Lands indicated that the soldier settlers, most of whom are engaged in dairy farming or sheep farming, have had a better year, although those engaged in orchards again had a poor season owing to inclement weather.

Rockefeller Foundation China Programme

THE Chinese Mass Education Movement, the Colleges of Public Affairs and Natural Sciences at Yenching University and the Institute of Economics of Nankai University received aid from the Rockefeller Foundation during 1935. In the part of the China programme centring round Nanking in south China, support was extended to the national health administration; to the Commission on Medical Education, and to three institutes interested in agricultural development; to the University of Nanking for its departments of agricultural economics and science; the National Central University for work in animal husbandry and veterinary preventive medicine; and the National Agricultural Research Bureau for insect control work. Local fellowships in China granted by the Foundation numbered 140.

Maintenance of Isothermal Chambers

AT the Institution of Electrical Engineers, Savoy Place, W.C.2, on May 5 at 6 p.m., Mr. L. B. Turner, a well-known radio-physicist of Cambridge, will present a paper describing a method he has devised of keeping a mains-operated isothermal chamber at a temperature constant to one thousandth of a degree centigrade. Although designed for a specific engineering application, it is likely to prove of interest to biological research workers and they are invited to attend the meeting. Biologists are specially interested in the maintenance of extremely constant temperatures; for minute changes of heat production in living tissue, detected by thermocouple, have been used as an index of vital process; and these changes can be measured only when the body under examination is protected from temperature fluctuation imposed from outside.

Conference on Large High Tension Systems

THE International Conference on Large Electric High Tension Systems will be held in Paris on June 24–July 3. It was established in 1921 with the sole object of studying the problems connected with the high-tension transmission of power. The organization and interpretation facilities will enable anyone speaking English to profit fully by the work of the Congress. An attractive programme of visits and excursions has been arranged and special terms are offered by many of the hotels and railways to registered members of the Congress. Further details may be obtained from the Secretariat, Avenue Marceau, 54, Paris, or the Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

Travelling Fellowships in Medicine

THE Medical Research Council invites applications for six Rockefeller medical fellowships for the academic year 1937–38. They are intended for British graduates who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. The Council also invites applications for four Dorothy Temple Cross research fellowships in tuberculosis. The object of these fellowships is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms". Further information and forms of application, returnable not later than June 1, are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S.W.1.

Royal Aeronautical Society Awards

ON April 26, Mr. H. E. Wimperis delivered his presidential address to the Royal Aeronautical Society on the subject of the natural limits to human flight, and the following medals and awards were presented: Society's Gold Medal to the late Señor J. de la Cierva, for his work on the development of the autogiro; Society's Silver Medal to F. W. Meredith, for his work on the automatic pilot; Society's Silver Medal to P. A. Cooke, for his work on the automatic pilot; British Gold Medal for Aeronautics to A. Gouge, for his achievement in the development of flying boats; Simms Gold Medal to Dr. H. J. Gough, for his paper "New Light on the Strength of Materials afforded by Modern Physics"; Simms Gold Medal to W. A. Wood, for his paper on "New Light on the Strength of Materials afforded by Modern Physics"; Taylor Gold Medal to Dr. G. P. Douglas, for his paper on "Cooling Problems with particular Reference to the work of the 24 ft. R.A.E. Tunnel"; Edward Busk Memorial Prize to Mr. G. H. Dowty, for his paper on "Retractable Undercarriages"; Pilcher Memorial Prize to H. Leaderman, for his paper on "The Fundamentals of Boundary Layer Theory with Some Applications to Aircraft".

Current Sunspots

AFTER some weeks of only moderate solar activity compared with the great activity shown from about last November until January, the recent appearance of an extensive active area of the sun may be noted. There are three chief groups of spots, one of them showing a rapid development from April 19, when the total area was only about 50 millionths of the sun's hemisphere, to April 22 when the area had increased to 1,750 millionths. Particulars of the groups of spots are as follows:

Date on Disk	Central Meridian Passage	Maximum Latitude	Maximum Area
April 15–28	April 22·4	10° S.	650
„ 16–29	„ 23·2	25° N.	900
„ 18–30	„ 24·6	19° N.	1750

Bright hydrogen eruptions were observed in association with the largest group on April 21 between 11^h and 12^h and 15^h–16^h U.T., whilst a series of small but very bright eruptions occurred on April 23. Another bright eruption, more extensive than any of these, was observed at Greenwich on April 25 between $8\frac{1}{2}^h$ and $11\frac{1}{2}^h$. Two magnetic storms were recorded at Greenwich beginning on April 24 at 12^h 0^m and on April 25 at 15^h 45^m. For the first storm, the ranges in declination, horizontal force and vertical force were 46′, 275γ and 145γ respectively, and for the second (up to April 26 10^h) 30′, 310γ and 105γ respectively. The second of these storms would seem to be related to the display of aurora reported by Mr. E. L. Hawke in *The Times* of April 27 as seen on April 25 from the Chiltern Hills.

The Night Sky in May

DURING the month, the duration of night decreases in the latitude of London by nearly 1¼ hours. The moon is new on May 10 at $13·3^h$ and full on May 25 at $7·6^h$, when a penumbral eclipse takes place. The greatest altitude of the moon at meridian passage (61·2°) is on May 12, and the least altitude, 15·9°, on May 26. Venus is a morning star rising just over an hour before the sun; on and about May 24 the planet is at its greatest brilliancy (magnitude −4·2). Conjunction with the moon occurs on May 8 at 15^h. On May 11 at 11^h, Mercury is in inferior conjunction with the sun, and a partial transit (invisible from Great Britain) of the sun's disk occurs the same day between $8\frac{1}{4}^h$ and $9\frac{1}{2}^h$. The planet Mars is conspicuous low down in the night sky and souths about midnight in the middle of the month. On May 19, Mars is in opposition, and nearest to the earth on May 28, when the apparent diameter of the planet is 18½″. On May 24 at 18^h, there is a conjunction with the moon, Mars being 0·6° northwards. Jupiter is a morning star of about mag. −2·0 in Sagittarius. Saturn rises in the dawn and can only be located with difficulty. About May 5, the maximum of the η Aquarid meteors occurs, the radiant being at R.A. 22^h 32^m: Dec. −2°, and on May 24 that of the Herculids, the radiant of which is at R.A. 16^h 36^m and Dec. +30°. Approximate positions for Comet Whipple (1937*b*) are given by Moller's ephemeris in I.A.U. Circular No. 653, as follows:

Date	R.A.	Dec
May 3	14^h $21·9^m$	+60° 28′
„ 7	22·7	60 18
„ 11	23·7	59 58
„ 15	25·0	59 29
„ 19	26·5	58 49

All times in this note are in U.T.; add 1^h to convert to Summer Time.

Announcements

THE proceeds of the Daniel Pidgeon Fund for 1937 of the Geological Society of London have been awarded in equal proportions to Dr. G. F. Claringbull, who proposes to investigate the geology and petrology of the Ross of Mull granite, and Mr. F. W. Cope, who proposes to map the central region of the Derbyshire dome, and to correlate the Lower Carboniferous rocks of the area with those of North Wales, Westmorland, and the type section of the Avonian.

PROF. GEORGE R. MURRAY, emeritus professor of medicine in the University of Manchester, has been made a member of a Departmental Committee appointed by the Home Secretary to consider the question of compensation for card-room and other workers in the cotton industry disabled by respiratory diseases.

DR. JOHN B. GRANT, of the Rockefeller Foundation, was recently decorated by the National Government of China on the occasion of the New Year with the Fifth Order of Beautiful Jade for his meritorious services in China. This order was awarded especially for his pioneering and developing public health work and in promoting medical education in China.

A ROYAL Rumanian Society of Genetics and Eugenics has recently been founded at Bukarest under the presidency of Prof. G. Marinesco.

WE have received from the Association of British Chemical Manufacturers, 166 Piccadilly, London, W.1, a copy of the second edition of the "Index to Acts of Parliament and Statutory Rules and Orders affecting the Chemical Industry", which comprises supplements bringing the work up to date to December 31, 1936. Copies may be obtained from the Association at the price of 2*s*. 6*d*. post paid, remittance accompanying the order.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 762.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Some New Characteristic Properties of Certain Industrial Dusts

WITH the assistance and encouragement of the Institution of Mining and Metallurgy and the Medical Research Council, we have continued an investigation, initiated four years ago under the auspices of the Institute of Chemistry, upon the chemical nature of dusts causing silicosis. Using the salicylic acid dust filters described in a recent communication[1], we have now obtained, probably for the first time, analysable samples of mine dust as breathed by the miner. The dust was produced by wet drilling and blasting of granite in a Cornish mine. On beginning the analyses of these samples, we immediately found that the loss on ignition, determined on the material dried at 105° C., was between 8·0 and 9·0 per cent, whereas the corresponding figure for the powdered granite rock was 0·6 per cent. Further analyses showed that the high loss on ignition was probably due to hydration of the dust, since it increased progressively from 3·7 to 5·7 and 8·5 per cent in samples taken at 10 ft., 20 ft. and 40 ft. from the working face.

On discussing these observations with our collaborators, Dr. Brammall and Mr. Leech, it was apparent that their recent work[2] on the reactivity of minerals to water and the way in which water may enter the crystal lattice was highly significant in elation to our problem. It suggested, *inter alia*, that such hydration as we had found should release alkalis from the crystal lattice, and on examining the alcoholic extracts obtained in separating the dusts from the salicylic acid filter beds, we found evidence of the presence of alkali in quantities oughly proportional to the degree of hydration of the parent dust.

Following up this result, our colleagues have made he very interesting observations recorded in another etter (p. 754), and we have made some preliminary xperiments upon the nature of the aqueous extracts of various dusts which are known to cause silicosis, ncluding typical pottery dusts and the dusts produced by crushing or disintegrating calcined flint, asbestos and felspar. Though we propose later in typical cases o make a gravimetric examination of the aqueous extracts of mineral dusts, we have for the present elied on the well-known silico-molybdate colorimetric est for silica, and the 'soluble' silica here referred o is that so indicated.

In every case so far examined we find that the ust, on extraction with water, yields both alkali nd 'soluble' silica, and that the amount of the latter reatly exceeds the normal solubility of quartz. The solubility' is a complex phenomenon and will require careful study as it depends not only on temperature ut also on time, on particle size and on the quantity dust submitted to the action of the solvent, and is largely affected by the presence of adsorbed films. Felspar dust produced by grinding the mineral under benzene and drying at 110° C. is unaffected by water, and even resists the prolonged action of steam at 110° C.; but it yields alkali readily on treatment with 95 per cent alcohol. The obvious inference, that felspar dust can hold very firmly a protective adsorbed film of benzene, suggests a possible means whereby dangerous dusts might be rendered innocuous.

Our experiments also indicate that the solubility of siliceous dusts may be profoundly affected by the presence of extraneous substances. For example, the apparent 'solubility' of finely divided silica (quartz) is greatly reduced (even to one tenth of the usual figure) by simple admixture with an equal weight of finely divided sugar charcoal, anthracite or bituminous coal. Further knowledge on this point may evidently serve to explain the remarkable differences, hitherto inexplicable, observed in the incidence of silicosis in different mining areas. On the other hand, the presence of sugar charcoal has little or no effect upon the quantity of soluble silica yielded under given conditions by asbestos, though it materially reduces the quantity of alkali liberated. Thus it is possible that the 'soluble' silica liberated from quartz by water is different in nature from the 'soluble' silica similarly liberated from asbestos, the former being presumably of greater molecular complexity.

The relationship of the alkali liberated from a dangerous dust to the simultaneous release of soluble silica is as yet obscure. The facts so far elicited are as follows: (1) the presence of sodium carbonate in water materially increases the yield of soluble silica by quartz dust; (2) extraction of asbestos dust with very dilute acid (sufficient only to neutralize the bulk of the liberated alkali) does not diminish the yield of soluble silica therefrom; (3) the presence of calcium hydroxide (but not calcium carbonate) in small proportion substantially inhibits the release of soluble silica from both quartz and asbestos. The evidence on this last point seems quite clear: the yield of soluble silica from 200 mgm. of a certain asbestos dust under standard conditions was reduced in presence of an equal weight of calcium hydroxide from 5·8 mgm. to 0·06 mgm., that is, to about one hundredth of the original value. Here again, evidently, is a very unexpected result which may quite possibly point to a means of making dangerous dusts safe. It is probably useless to supply lime dust, which would become largely carbonated before reaching the lung surface, but admixture of a dust such as that of fresh cement, capable of yielding caustic lime on hydrolysis, might well serve to mitigate the effects of dangerous dusts.

While much work remains to be done in following up these preliminary experiments, it seems already to be clearly established that *freshly fractured* surfaces of silica and some mineral silicates are in a highly reactive state and readily yield both alkali and 'soluble' silica on contact with water, and that for the finest particles, of the order of 5–1 μ and less, in freshly formed mineral dusts this reaction to water, though superficial, is quantitatively important. Thus, chemical changes in minerals which normally are extremely slow may, in the case of very fine dusts, proceed very rapidly to a substantial extent. It follows that, in many cases, quite apart from any effect of sedimentation, dust solids by the time they reach the lung surface, are quite different chemically and mineralogically from the mass which has given rise to them.

As most medical opinion rejects the idea of mechanical damage as the cause of silicosis, it seems probable that the changes observed in the tissues must be attributed to the chemical effect of the dust particles, that is, to the chemical effect of the soluble substances they yield up to the tissues. Therefore there seems reason to hope that the further study of the solubility of dusts, both dangerous and non-dangerous, which is being actively carried on in these laboratories, may throw useful light upon the causation of silicosis and allied diseases such as asbestosis, and may possibly suggest methods of minimizing their incidence.

On several occasions we have found that fine dusts which have become aggregated by settlement or have been for some time exposed to air appear to be much less reactive than when freshly formed. This observation may explain the failure of attempts in the past to induce silicosis in animals by exposing them to artificially raised siliceous dust clouds. In the light of present knowledge, it might be anticipated that such 'dead' dusts would be relatively innocuous. When the present investigations have developed further, it may well be worth while to institute fresh animal experiments on the effects of dust inhalation; but if these are to be significant, it must first be clearly established that the dusts used are really dangerous, that is, that their chemical properties are similar to those of dusts which are known certainly to cause silicosis.

Hydrolysis of Rock-forming Minerals

As members of a small team organized by Prof. H. V. A. Briscoe to study, geochemically, the hydrolytic effects of humidity on mine dusts ($< 1\ \mu$), we have recently investigated the conditions under which various mineral silicates are degraded by simple aqueous extraction towards layer-lattice end-products belonging to the sericite, chlorite and clay types, and have examined the sols obtained.

The alkalinity imparted, instantly, to cold water by powdered soda-glass is a commonplace fact—readily demonstrable by using water containing an indicator such as phenolphthalein. Tamm[1] has recently shown that finely powdered orthoclase, muscovite, stilbite and wollastonite are very hygroscopic and are partially dissociated in water, which then gives an alkaline reaction. Incidentally, he suggested that the end-product of leached orthoclase dust is related to muscovite. The behaviour of beryl, calcite, orthoclase, albite and wollastonite was studied by Stevens[2] on similar lines. Thugutt's work on the hydrolysis of leucite and labradorite[3] involved the use of closed tubes at high temperatures, 182°–238°.

We find that, by moistening dust-fine mineral particles with cold water, a similar reaction, variable as regards intensity, is readily obtainable with most of the common rock-forming minerals: for example, biotites and other basic micas; hornblendes and other amphiboles (including asbestos); wollastonite, diopside, hypersthene, augite, aegirite and other pyroxenes; olivine, apatite, sphene and some varieties of tourmaline; grossularite, melanite and some varieties of almandite; members of the chlorite and epidote groups; calcite, aragonite, magnesite, dolomite; brucite and chondrodite; all feldspars, notably the more calcic plagioclases.

Sericite, hydromuscovite and true muscovite are among the less readily reactive species. Some chlorites and 'sericites' isolated from slates are essentially inert, though there is evidence that a clay species akin to pyrophyllite is admixed with the 'sericite' in some of these cases. The behaviour of common clays under the same experimental conditions is somewhat erratic, and often in strong contrast with their individual responsiveness to base-exchange conditions.

Sericite, hydromuscovite[4], muscovite and the basic micas yield up an appreciable amount of their alumina, etc., on treatment with weak solutions ($< N/5$) of salines such as salt and potassium chloride, extraction being accelerated by heat. Paver and Marshall[5] noted this reaction, and its rapidity, in the case of certain clays. Seven basic micas treated by us yielded hydroxides of aluminium and ferric and ferrous iron (with some magnesia), which were readily removed from the mineral particles by very dilute ($< N/40$) hydrochloric acid and precipitated from the filtrate by ammonia. The residues in the two cases tested had the properties of a true mica grading towards 'bleached biotite'.

Tamm[1] noted that orthoclase dust produced by grinding under benzene was neutral towards water. We confirm this finding, and extend its application to mineral dusts in general if they are produced by grinding under either benzene, or bromoform, or methylene iodide, which appear to endow the particles with a protective film. This neutrality t water is partly overcome by further attrition, and may be entirely cancelled by the use of aqueous alcohol.

The comparative ease with which dust-fine miner particles are partially dissociated and leached of som portion of their bases by cold water alone shows the 'mineral solubility' can be a misleading term[6]. Th facts merit adequate consideration in relation to th genetic history and petrology of sedimentary rocks they bear directly on (*a*) the geochemistry of weathe ing processes; (*b*) the extent to which mineral chang is dependent on the grade size of the detrital particl and on the solutes present in surface and unde ground waters; (*c*) the metastability of sedimente mineral particles under environmental conditio liable to oscillate between aggradation and degradation; and (*d*) the extent to which original mineral composition (and parental sources) can be inferred from the actual mineral assemblage in any particular case.

Active Absorption of Anions in the Animal Kingdom

IN recent papers (1933–37), Lundegårdh[1] has demonstrated in the roots of plants a mechanism for absorbing and concentrating salts out of very dilute solutions. This mechanism utilizes energy derived from the oxidation of sugar and acts by transport of anions (in Lundegårdh's experiments, NO_3^- and Cl^-) from the outside medium through the active cells to the inside. It is a specially important point that the energy used up is proportional to the anion exchange, while cations cause no increase in respiration. In carbonate solutions no active transport can take place and the exchanges of cations are slight only.

I submit that a mechanism closely resembling Lundegårdh's is of widespread occurrence and of great biological significance in the animal kingdom.

H. Koch (1934)[2] discussed the occurrence in a number of freshwater arthropods of certain groups of cells which take up silver nitrate from very dilute solutions and become deeply stained when the silver chloride formed is afterwards reduced under the influence of light. He suggested that these special cells normally act by actively absorbing salts which go to maintain the osmotic concentration of the organism. Working in my laboratory, he was able to prove the correctness of this suggestion.

I studied[3] simultaneously the active absorption of salts by frogs. Frogs which have been deprived of a certain amount of salt will take up actively Cl^- ions from solutions down to 10^{-5} molar or less, either with Na^+, (K^+) or in exchange against HCO_3^-. While in plant roots the process is apparently going on indiscriminately all the time, in the frog's skin it is definitely regulated. It takes place only when the salt content of the body has been depleted, and when potassium chloride only is available it soon stops. Calcium is scarcely taken up at all, but from calcium chloride there is a quantitative exchange of Cl^- ions against HCO_3^-. Br^- is absorbed just as rapidly as Cl^-, and I find now that the nitrate ion also is absorbed from a *n*/1,000 solution. In an experiment with sodium chloride plus nitrate, each 0·002 molar, the initial uptake of Cl^- was thrice as rapid as that of NO_3^-. Iodine penetrates only slowly and probably by diffusion.

Corresponding mechanisms exist in a large number of freshwater animals where they seem to be located in the gills. I have found them in several fishes, crustaceans, gastropods and mussels.

In the eel in sea water, a mechanism for excreting Cl^- through certain cells in the gills was demonstrated by Keys (1931)[4], and it is significant that this mechanism cannot act in the opposite direction when the eel is living in fresh-water.

Ingraham and Visscher (1936)[5] describe a mechanism, which is probably similar, for the absorption of Cl^- from the intestine, and I venture the prediction that the Cl^- absorption taking place in the kidney tubule is also similar in nature. It is well known that bromide is not distinguished from chloride by the kidneys.

A Lead Extrusion Phenomenon

IT has been known for the past two decades that in the extrusion of lead cable sheaths and pipe on the hydraulic press, the presence of oxides may result in the existence of irregularities in the structure which are brought to light by suitably etching a polished section. In this case, the feature originates in the oxidation of a surface of the metal exposed at an earlier stage in the process, and the layer of oxide, formed at right angles to the direction of flow, may be folded over, and appear afterwards as a radial line of weakness in the finished pipe. An important distinguishing feature in this type of irregularity is the fact that the crystal structures on the two sides of the feature are quite separate and distinct; there is no growing of the crystals across the line of oxide (see Fig. 1).

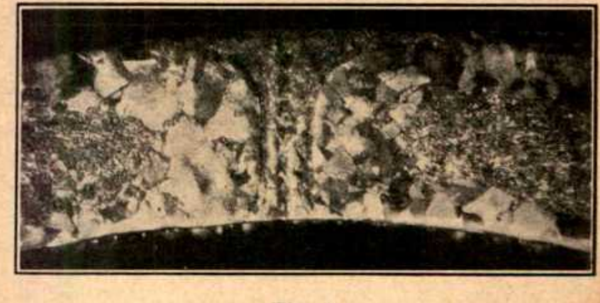

Fig. 1.

WELL-KNOWN INCIPIENT FISSURE DUE TO OXIDE LAYERING. CRYSTAL SYSTEMS DISTINCT ON TWO SIDES.

In the production of pipe and cable sheath by the continuous lead extrusion machine, the formation of oxide layers has been avoided by the exclusion of air from the device. Notwithstanding the complete absence of oxidation, however, it has been found possible, by the use of bridge supports dividing the flow of lead on its passage to the forming die, to produce radial lines in the etched section of the finished pipe showing that an impression has been left on the structure of the lead. In this case, although the crystals grow continuously across the line, it seems to be quite clearly established that the splitting of the lead stream by a steel part before final amalgamation results in a modification of the structure which may be brought to light by subsequent deep etching.

The former well-known defect consisted of a 'mush' of small non-crystalline particles, dross, etc., and was frequently backed up on each side by sandwiches of crystals and mush, evidently on their way to form the defect. In that case, however, the crystal structure was definitely broken at the boundary line, whereas with this new phenomenon, all my observations indicate that the line brought out by deep etching is not a boundary between two separate crystal systems, but actually passes through the crystals themselves and, moreover, passes continuously from one crystal to the next.

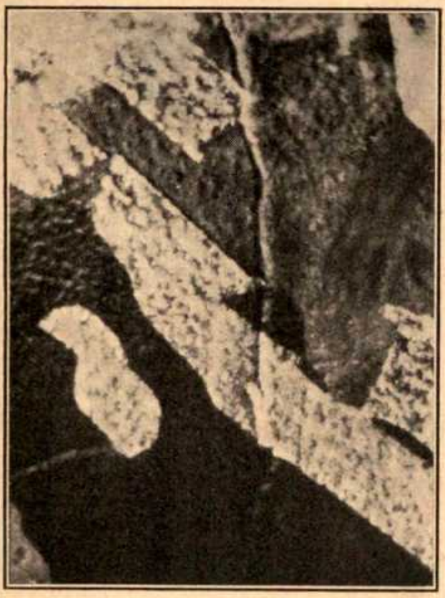

Fig. 2.

LINE IN STRUCTURE, BROUGHT OUT BY DEEP ETCHING, WHERE METAL HAS FLOWED OVER A DIVIDING MEMBER AND JOINED UP AGAIN. ONE HOMOGENEOUS CRYSTAL SYSTEM.

The distinction is shown in the two photomicrographs (Figs. 1 and 2). There are one or two possible explanations of the phenomenon of Fig. 2. Although oxide is excluded from the machine in which this structure has been produced, it may easily happen that a small quantity of oxide disseminated throughout the mass of lead, probably in solution, could be segregated at the dividing barrier and produce the effect, at the same time being so small in quantity as to permit the free recrystallization of the metal as in Fig. 2, after the divided stream has joined up again beyond the barrier. A second possible explanation is that in rolling and rubbing over the dividing steel surface, a segregation of the very small quantities of impurities always found in lead may take place, and that the 'line', therefore, indicates a difference in alloy which, while very slight and insufficient to interfere in any way with the formation of the crystals, is still sufficient to cause differential solubility through electrolytic local action and the bringing to light of the feature through the local depression. As would be expected from the integrity of the crystal system, the existence of the feature does not reduce the bursting strength of the pipe and, while suitable modifications of the machine have been made to obviate the effect, its appearance would not seem to share the disadvantages of the former type of split lead due to oxide inclusions.

A Method of Measuring the Magnetic Moment of Free Neutrons

F. BLOCH[1] has recently pointed out the possibility of producing partly 'polarized' neutron beams, that is, beams which contain more neutrons of one direction of spin than of the other. The method consists in passing a beam of slow neutrons through a plate of magnetized iron, the 'polarizer'; the polarization of the beam can be demonstrated by passing it through another iron plate, the 'analyser': a change in the intensity of the beam would be expected, according to Bloch, on reversing the magnetization of the analyser. Such a change has in fact been observed by Hoffman, Livingston, and Bethe[2].

The magnitude of the polarization effect was shown[2] to be in agreement with the value $\mu_n = 2$ N.M. (1 N.M. = 1 nuclear magneton = 1/1840 Bohr magneton) for the magnetic moment of the neutron deduced from the moments of the proton (2·5–2·9 N.M.[3,4]) and the deuteron (0·8 N.M.[5,4]). This calculation is based on a careful study of the density distribution in the iron of those electrons which produce ferromagnetism.

We would like to point out a direct method of measuring μ_n which also permits a determination of its sign (that is, its direction relative to the direction of spin). Our method makes use of the Bloch effect for obtaining polarized neutron beams, but does not necessitate the application of the theory of ferromagnetism.

The method consists in studying the depolarizing effect of a magnetic field through which the neutrons pass on their way from the polarizer to the analyser. If this field, H, is perpendicular to the polarizing (and the analysing) field the neutrons start to precess with an angular velocity $\omega = 4\pi\mu_n H/h$ (h = Planck's constant). On leaving the field the neutrons have turned through an angle $\varphi = 4\pi\mu_n Ha/hv$ (a = length of field, v = neutron velocity), and consequently the polarization effect (the change in beam intensity when the analysing field is reversed) is diminished by a factor cos φ. Thus the study of the dependance of the polarization effect on H permits a determination of μ_n. Taking $v = 2 \times 10^5$ cm./sec., $a = 3\cdot5$ cm., $\mu_n = 2$ N.M., we find that a field of about 4 gauss should turn the neutrons through 90° and thereby make the polarization effect disappear.

We have made some preliminary experiments t demonstrate the existence of this depolarization effect (Qualitative evidence has been obtained by Powers Beyer, and Dunning[6].) Our arrangement was similar t that of Hoffman, Livingston, and Bethe[2]. As polarize and analyser we have used flat iron rings which wer wound throughout their length in order to minimiz any external field action of the magnetizing current Still, it was soon found best to switch off the magnetizing current during the measurements and to wor with the permanent field only. A long solenoid wa placed between the iron rings in order to produce the depolarizing field H.

With $H=0$, the polarization effect was found to be $(0{\cdot}65 \pm 0{\cdot}28)$ per cent of the total count (of which about one half was due to thermal neutrons). With $H=4$ gauss, the polarization effect was negative, but at the limit of error $(-0{\cdot}36 \pm 0{\cdot}31)$ per cent. At $H=2$ gauss an intermediate value of $(+0{\cdot}29 \pm 0{\cdot}36)$ per cent was obtained. These results are in qualitative agreement with the assumption $\mu_n = 2$ N.M. The errors given are mean square errors; similar figures were obtained on computing the errors in the traditional way from the fluctuations of the single results. Altogether, 1·2 million counts have been made.

A new and improved apparatus is being prepared in order to determine the amount and the sign of μ_n; the sign can be found by placing polarizer and analyser at an angle and by studying the direction of precession depending on the direction of the magnetic field.

Radioactive Neon

IN a previous note[1] it has been reported that the radioactive helium formed by bombarding fine-grained beryllium hydroxide with neutrons can be transferred by a stream of gas through a tube from the place of activation around a neutron source to a Geiger counter placed at some distance.

By bombarding sodium or magnesium with fast neutrons, a radioactive substance of 40 sec. half-value period is produced[2], which is generally assumed to be $^{23}_{10}$Ne. So far as I am aware, no chemical proof has been obtained. It therefore seemed of interest to attempt to use the above method to decide whether the active substance in question is a gas. Magnesium hydroxide was precipitated together with ferric hydroxide in various proportions by the method of O. Hahn[3] in order to give it a high emanating power. The dried precipitates were bombarded with neutrons from a beryllium-radon source of 200 millicuries, and air from an aspirator was passed at a suitable rate through the samples and then through a glass tube to the thin-walled jacket around the counter. No definite effect was found; it follows from the relative yields by bombardment of beryllium and magnesium with neutrons, that if radioactive neon is given off by the bombardment of magnesium, one would expect only a very weak effect (just detectable) by this method. This is mainly due to the small relative abundance of $^{26}_{12}$Mg.

In the case of sodium, the effect to be expected is much larger if the radioactive neon can be removed from the crystals of the sodium compound during an interval comparable to 40 sec. Commercial sodium stearate[4] proved suitable, and an unambiguous effect was found. In Fig. 1, the number of counts per minute is plotted against the rate of the air stream in cubic centimetres per second. From the volumes of the activation chamber, the connecting tube and the jacket around the counter, one can calculate the shape of the curve to be expected when the radioactive gas has a given half-value period T. The curve drawn in the figure corresponds to $T = 40$ sec. The experimental points are not in disagreement with this, although a slightly smaller value of T (35–40 sec.) would fit a little better. With sodium butyrate, a similar effect was obtained.

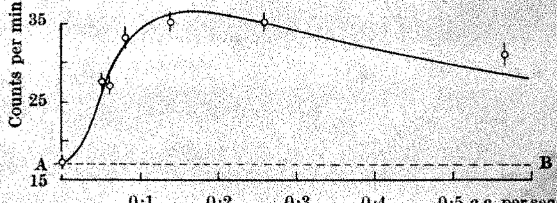

Fig. 1.

RELATION OF NUMBER OF COUNTS TO RATE AT WHICH THE AIR STREAM PASSED TO THE COUNTER. AB REPRESENTS THE γ-RAY EFFECT.

The effect here described may be of interest for the study of the emanating power of sodium compounds.

The Cosmological Constants

PROF. P. A. M. DIRAC's recent letter in NATURE[1] encourages me to direct attention to certain 'coincidences' which I had noticed some years ago, but which I have been hesitating to publish from the conviction that purely 'dimensional arguments' will not lead one very far.

If we consider the natural constants h (Planck's constant), c (velocity of light), H (mass of the proton), G (the constant of gravitation), we can form the following combination M_α which is of the dimension of mass:

$$M_\alpha = \left(\frac{hc}{G}\right)^\alpha \frac{1}{H^{2\alpha-1}}, \qquad (1)$$

where α is an arbitrary numerical constant. Now a particular case of the above occurs in the theory of stellar interiors, namely, when $\alpha = 3/2$. Then

$$M_{3/2} = \left(\frac{hc}{G}\right)^{3/2} \frac{1}{H^2} \doteqdot 5{\cdot}76 \times 10^{34} \text{ gm.}, \qquad (2)$$

which is about thirty times the mass of the sun. Now, the apparent success of steady state considerations in 'explaining' the observed order of stellar masses can be traced to the circumstance that the above combination (2) of the natural constants gives a mass of the correct order. It may be noticed that apart from numerical constants, (2) is the same as the upper limit to the mass of completely degenerate (degenerate in the sense of the Fermi-Dirac statistics) configurations[2]. The occurrence of (2) in stellar structure equations need not cause any surprise, since one can easily convince oneself by considering two homologous stellar configurations that if a formula for mass exists, it must contain the mean molecular weight μH with an inverse power 2, and this would, according to (1), fix the value of the exponent α as 3/2.

It is of interest to see what (1) leads to for other values of α. If $\alpha = 2$, then

$$M_2 = \left(\frac{hc}{G}\right)^2 \frac{1}{H^3} \doteqdot 9\cdot5 \times 10^{20} \text{ mass of sun} \qquad (3)$$

If we divide M_2 by H, then we get for the corresponding 'number of protons or/and neutrons',

$$N = \left(\frac{hc}{G}\right)^2 \frac{1}{H^4} \doteqdot 1\cdot1 \times 10^{78}, \qquad (4)$$

which is of the right order as the 'number of particles in the universe'. We may notice that if $G \sim t^{-1}$ (t is Milne's cosmological time), then $N \sim t^2$, which agrees with Dirac's speculation.

It may be further pointed out that if $\alpha = 1\frac{3}{4}$, then

$$M_{1\frac{3}{4}} = 1\cdot7 \times 10^{11} \text{ mass of sun}, \qquad (5)$$

which is of the same order as the mass of our Milky Way system. If we 'identify' $M_{1\frac{3}{4}}$ as representing the mass of a galaxy (external or otherwise), then we should have, according to Dirac's ideas, that the 'number of particles in the galaxy' should vary as $t^{1\cdot75}$ Similarly, the number of particles in a star should vary as $t^{1\cdot5}$.

Sources of Inaccuracies in Spectrographic Research

IT may be of interest to point out that there is considerable evidence entirely confirmatory of Mr. D. A. Webb's observation[1] that very intense spectra due to element A, present in minute concentration in electrodes B, can be brought out by addition of C.

Development of spectra in discharges is in the main due to one of two causes, namely, direct collisional excitation as a kinetic effect, or receipt of energy from another excited body, that is, a collision of the second kind. Other processes such as chemiluminescence, recombination reactions, etc., are generally of much smaller account.

As regards the first of these, it seems permissible, in view of the very wide variations in electrical factors such as electron speeds, etc., to suppose that in spite of considerable differences in excitation functions and excitation potentials, among both the various elements and their different spectral series, the genesis of excited states will be so much a matter of probability that the ratio of the intensity integrals of spectra due to A and to B, may be taken as a fair measure of their relative concentrations.

Excitation according to the second of these causes may lead to very different results. The probability that transfer of energy will follow the contact of excited and unexcited bodies, is here governed by two principles. From energy considerations alone (Franck's 'resonance rule'), it is expressed by a somewhat complex function which in practice means that the chance of such excitation increases very much as the discrepancy $\triangle E$ between the energy of the donor, and that of the nearest excitable level of the acceptor, decreases. In the mercury-sensitized fluorescence of sodium, for example, the line $\lambda = 4423$ A. is extremely intense, since it proceeds from a level lying within 0·02 v. of the mercury 2^3P_1 state, other lines (for example, 6 D, 8 S) being only one eighth to one quarter as bright, although $\triangle E$ is here[2] only about 0·15 v.

Excitation is also markedly favoured, given good energy resonance, if the process can take place without change in the overall multiplicity, S, of the system (Wigner's rule). To this is due the thirtyfold enhanced probability of:

$$\mathrm{Kr}(2^3P_2) + \mathrm{Hg}(1^1S_0) \rightarrow \mathrm{Kr}(1^1S_0) + \mathrm{Hg}(5^3D_n) + 0\cdot038 \text{ v.}$$

as compared with:

$$\mathrm{Kr}(2^3P_2) + \mathrm{Hg}(1^1S_0) \rightarrow \mathrm{Kr}(1^1S_0) + \mathrm{Hg}(5^1D_2) + 0\cdot033 \text{ v.}$$

In the first reaction, where the mercury triplets are excited, S remains constant at unity, whereas in the second case, where the singlets appear, S has fallen to zero[3]. It would appear not improbable that there may be yet a third factory, depending upon the *type* of level being excited, but the evidence here is as yet very slender[4]. So many cases are known, however, where the first principles are valid[5], that it will be clear that considerable caution must be adopted, in spectographic analysis, as regards metrical interpretation of the results. Mr. Webb's communication is a welcome and timely reminder to this effect.

Germination of Oospores of Onion Mildew, *Peronospora Schleideniana* W. G. Sm.

IN a previous letter[1], the germination of the oospores of the downy mildew of onions, *Peronospora schleideniana* W. G. Sm., was briefly discussed. Commenting on this letter, Miss Blackwell[2] remarked on the general difficulty experienced in germinating such fungal spores, and points out that time is a factor as well as maturation.

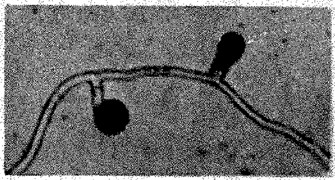
Since then, Wolf and his associates[3], working on somewhat similar lines to mine, have recorded the germination of oospores of the downy mildew of tobacco. They state that less than a dozen oospores germinated out of several thousands tested, and growth of the germ-tubes was very limited. In view of our general lack of knowledge concerning the behaviour of such oospores, the following additional information regarding those of the downy mildew of onions may be of interest to other workers.

One per cent of the oospores germinated at the end of four years, but it was evident that the remainder had not lost their vitality, since:

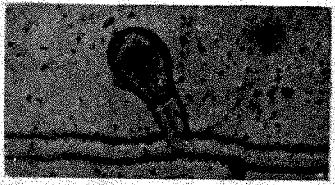
(*a*) The changes occurring in the oospores indicated that they were not dead.

(b) A slight increase in germination occurred after four years, though two per cent was the highest obtained in water.

(c) Eventually it was found that on adding potassium permanganate solution (0·01–0·02 per cent) to water containing the oospores, the latter being 5–6 years old and weathered out-of-doors, 60–85 per cent germination occurred inside forty-eight hours at 15°–20° C., 0·05–1 per cent occurring in controls. The oospores were placed in water on microscope slides, sufficient of the permanganate solution added to give a definite pink colour to the water, and cover slips applied. The reagent did not appear to act directly on the oospores, as scarcely any germination took place when they were mounted perfectly clean. If, however, plenty of organic remains were present, germination occurred.



(a) × 200



(b) × 400

Fig. 1.

Peronospora Schleideniana.

The germ-tube produces a hypha which grows to a length of 2–8 mm., with more or less subsidiary branching, when longitudinal growth apparently ceases. After this, at any time in 3–10 days, a second type of branch arises usually on the main hypha. These branches are very short, and may be either scattered along the hypha or adjacent to each other, when they are often on alternate sides, as shown in Fig. 1 (a). These short branches are terminated by a single cell (Fig. 1 b), the latter varying in size. Three to nine of these bodies may occur on a hypha produced by a single oospore, so that we have here a limited saprophytic existence of the fungus in water. Some oospores germinate without forming any of these bodies; the significance of this is not yet known.

The treatment of eighteen-months old oospores with the permanganate solution gave no result. This confirms Miss Blackwell's observation that the time factor as well as maturation is necessary for the germination of these fungal spores.

The Technique of Plastic Reconstruction

PLASTIC reconstruction is desirable in almost any structural embryological investigation. At the best of times it is a laborious process, yet I feel that the difficulty of obtaining or preparing suitable plates may often be a determining factor in preventing the still more frequent use of this method. In a department where there is a constant demand for plates, such difficulty will not arise as the necessary apparatus will be permanently set up and a trained technician will be available, but when the demand is sporadic difficulties may occur.

It is in the hope that some of these difficulties may be lessened and that further stimulus to the use of plastic reconstruction may be given, that I am writing this letter.

Plates may be made of wax[1] or other suitable material. The chief advantage of wax is that it allows plates of any predetermined thickness to be made. The plates are usually rolled on a lithographic stone[2] or on a cast-iron plate[3,4]. The former is cumbrous and very liable to crack, the latter is incorporated in a special apparatus; neither is readily transported and set up wherever happens to be immediately convenient.

Some time ago, I tried a sheet of plate-glass (24 in. × 15 in. × ½ in.) as a substitute for the lithographic stone, and I have been using the method since with considerable satisfaction. The glass is placed on any suitable end-supports, so that it rests about 4–6 in. clear of the bench. After levelling, it is gradually heated by waving a gas poker underneath the free surface between the supports. (The 'poker' is easily made by sealing the end of a piece of brass tubing and punching a series of suitably spaced holes in it.) When the glass is sufficiently hot, it is painted with turpentine, a sheet of Flint paper is placed on it and brushed down with turpentine so that all the air between the paper and the glass is expressed, the guide rails are placed in position, and the wax is poured and rolled in the usual way. The wax maintains the temperature of the glass without further heating. Overheating of the wax and of the roller must be avoided, otherwise there is a risk of cracking the glass.

The advantages of this method are that the plate-glass is cheap and readily obtainable, it is easily moved from place to place and set up wherever desired, and it is speedily heated: it is, in fact, easier to handle in every way than a lithographic stone.

There are obviously great advantages in using material of more resistant qualities than wax, apart from the fact that the need for making the plates is eliminated. "Holzpappe" was suggested by His[5] so long ago as 1885; cardboard was used by Broman[6] in some of his reconstructions, and this method was elaborated by Triepel[7].

The blotting-paper method, originally suggested by Gage[8], appears now to be in general use. It is, however, expensive, and I wish to direct attention to the use of a wood-pulp board which serves the purpose equally well and is less than half the price of blotting-paper. I have been using what is termed "4 sheet pulp board 44 in. × 32 in.", the retail price of which is eight shillings per quire. After impregnation with paraffin wax (melting point about 55° C.) I find that this board approximates closely to a thickness of 1 mm., and it cuts very readily. This wax impregnation, which is carried out by soaking the sheets in the melted wax until all the air has been driven out, is important as it facilitates the process of cutting to a marked degree; it may be that it is a well-recognized step in the technique, yet I have only noticed it mentioned once in the literature[9].

I have found that it is useful to fill in the 'steps' in the completed model (if it is desirable to do so) with plastic wood instead of the usual wax; considerably greater rigidity is thus obtained, and the use of fine sand-paper gives a finished surface.

Air Raid Precautions

WHILE we appreciate the fulness of the treatment which has been accorded to our book "The Protection of the Public from Aerial Attack", we should be grateful for the opportunity of commenting on certain points in the review in NATURE of April 10, p. 606. Regarding the purpose of the book, General Foulkes says, "It suggests no better defensive measures than those recommended by the Home Office". Better methods are not lacking, and our object simply was to provide some scientific data concerning the proposed precautions—because no such data had been published and we felt that the unsupported statements of Government spokesmen concerning their efficiency were no substitute for scientific fact.

The reason why a privately manufactured mask was tested is expressly stated in the book. Although we applied to the Home Office for specimens of the Government mask for civilian use and attempted to procure them through other channels, we were unsuccessful in obtaining any. The type of filter in the mask which we used was, however, the same as that described in the Press for the Government mask. General Foulkes does not mention the passage of arsenical smokes through gas masks of the type of the Government mask. From simple experiments with cigarette smoke on the free masks on exhibition at the Royal Horticultural Hall, it seems probable that they could transmit a few per cent of any arsenical smokes drawn through them. Is it therefore justifiable to claim that these masks give complete protection against all air-dispersed poisons? The French Government uses an entirely different type of filter—a pleated paper one—in all its service masks, and this mask transmits very much less arsenical smoke.

General Foulkes remarks that "in many of the poorer homes completely gas-proof shelters can only be provided with great difficulty" and continues "but that is no reason why the remainder should not be protected". We agree, but the number of poorer homes which cannot be gas-proofed is disturbingly great. The reviewer in discussing the carbon dioxide experiments quotes from Mr. Geoffrey Lloyd that they "had been proved to be open to grave criticisms". What are these criticisms? They are still unknown to us, though they have been repeatedly asked for in the House of Commons. Since General Foulkes says that "experiments showing the rate of leakage *from the open air into a gas-proof room* would have been of far greater interest", it is surprising that he makes no mention of the experiments we did in which gas passed from the outside to the inside of a gas-proofed room. These were of two kinds (see pp. 95–105) and showed that air passes readily from the outside into a gas-proofed room under normal atmospheric conditions. The suggestion that conditions in dug-outs are comparable with those in ordinary houses is obviously false, as the kind of walls, ceiling and floor and the degree of exposure are different. When General Foulkes says, "I do not believe that anything approaching a concentration of 5 per cent of gas can be established in the open air by an aerial or any other kind of bombardment", we may well agree with him. But the strongest concentration of non-persistent gas we assumed for our calculations corresponded to 0·004 per cent by volume of phosgene. It is stated by Engelhard that concentrations higher than this can be reached in the field. It is stated in a recent book ("Chemicals in War", by Prentiss) by an author who seems to have had much experience of these matters, that seven aeroplanes could establish a concentration of mustard gas of 0·025 gm./cubic metre when the atmospheric temperature was 17° C. over an area of 2·5 square miles. Such concentrations would be fatal if breathed for an hour, so that our calculations would appear to be well founded on reasonable premises. General Foulkes would apparently trust a "good strong wall-paper". We would not, nor would we trust a brick built room, for the data published by Pettenkofer in 1865 and in the *Architectural Forum* of March 1924 show that the ventilation of a room is very largely through the actual brick of the walls and is much less through the windows and doors than is commonly supposed.

The chief burden of General Foulkes's argument is that our experiments have little relevance to actual war conditions, that they are essentially academic and not practical. He considers the measures proposed by the Government as adequate to deal with the kinds of attack which are probable and points to the experience of the Great War. We believe, however, that with the immensely increased potentia force of modern air fleets, attacks of a different order of intensity are now possible, and that against suc attack the measures are hopelessly inadequate. This is certainly the belief of the French Government as judged by the methods actually being put int practice, which include among other provisions (*a*) evacuation, for the duration of the hostilities, o the inessential population (old persons, some wome and children), (*b*) nightly evacuation of all thos required for essential services, (*c*) bomb- and gas proof shelters with filtered ventilation in cellars o large and strong buildings, (*d*) communal shelter for districts with old and small houses (undergroun stations will be used for the purpose). English town are exposed to a danger at least as great and requir no less effective protection.

We have no desire to create panic, but those wh persuade the people of Great Britain to believe tha they are safe when they are not are inviting pani and worse than panic in the case of war. We woul be lacking in our duty as scientists and citizens if we were to accept, without question, assurances of the validity of which we have not been convinced.

Finally, we must admit that we would prefer to obtain "a still greater degree of safety . . ." by stopping war altogether, but we do not feel that this preference invalidates our results. Experiments are to be believed, not on account of the authority or bias of the experimenters, but because they can or cannot be repeated by anyone who chooses to do so. We would accordingly urge that the whole question of the protection of the population from aerial attack should be studied openly by representative scientists; then a rational estimate can be made of the probable efficiency of any measures which are finally adopted.

ONE of the grievances of the authors seems to be that they issued a challenge to the Home Office to produce the data on which their gas protection experiments were based, and that this challenge has been ignored.

The Government has, no doubt, its own reasons for not publishing the data, but it would be fair to suppose that the recommendations it has made are well supported by scientific facts which have been established by its own advisers—men, as I pointed out, who have carried out all its poison gas experiments during the last twenty-odd years.

The authors quote from a book recently published in America by Colonel Prentiss, and they refer to him as one "who seems to have had much experience of these matters".

I agree; so let me in turn quote from the chapter "Protection of Civil Population": it will be seen that the Home Office recommendations are supported in full.

> "Shelter from chemicals launched during air raids s to be obtained for the most part by the utilisation of existing structures with such gas-proofing as may be justified. The erection of special collective shelters designed exclusively for the protection of civilians during aerial attacks is only warranted under exceptional circumstances; at best, such buildings can accommodate no more than an insignificant proportion of the inhabitants of any community. . . .
>
> "The individual or small-group shelter of this type will not require special air-purifying devices to counteract noxious gases, but instead will be airealed when occupied, its occupants depending on the air present in the room for the necessary oxygen. Arrangements should be made in advance to prevent all in-drafts of air, while the shelter is in use, and overcrowding with consequent rapid exhaustion of ree oxygen must be avoided."

An Air-borne Plant Virus

IN a recent issue of NATURE[1], Dr. Kenneth Smith described the virus of a new disease of plants as being "air-borne". The term in this connexion implies: (1) that the virus agent can escape from the tissues of the infected plant into the air under natural conditions; (2) that it is carried in the air; and (3) that the air-carried virus can infect a normal healthy plant.

In the light of the generally accepted view that the virus is intimately connected with the protoplasm of the host cell, and that it is unable to enter an uninjured protoplast, the demonstration of the easy passage of a virus from a plant into the air would be of great interest. It is not clear that Dr. Smith has succeeded in demonstrating this. All he has shown is that in three out of an unstated number of experiments, plants were found to be diseased after they had been rubbed with cotton-wool pads through which the air of a glass-house had been drawn. If the virus is present in the soil, as Dr. Smith suggests, and if it resists desiccation as he now states[2], it is not unreasonable to suppose that in the dust of a glass-house some traces of the virus might be present. Even if this were demonstrated, however, it would scarcely prove that the virus is air-borne; tobacco leaf dust contains the virus of the tobacco mosaics.

Dr. Smith has not shown that the virus does in fact reach the air from the tissues of a living infected plant, or that being in the air it can infect normal healthy plants. Until this has been demonstrated under controlled conditions, Dr. Smith's description of his virus as "air-borne" would appear to be premature.

JOHN CALDWELL.

Department of Botany,
University College,
Exeter.

---

[1] NATURE, 139, 370 (Feb. 27, 1937).
[2] cf. Smith, NATURE, 136, 396 (Sept 7, 1935).

DR. CALDWELL's chief criticism is directed against a point which has already been proved[1], namely, the ability of this virus to enter the roots of a plant without the aid of any known external agencies. Dr. Caldwell says that the term "air-borne" implies "that the virus agent can escape from the tissues of the infected plant into the air under natural conditions". I fear this is wider than my conception of the term; I only meant that the virus was carried in the air, with the added implication that it was able to reach and infect virus-free plants by this means. It never occurred to me that anyone would suppose that the infected plant was discharging virus particles into the air after the manner of an influenza patient. Indeed, the following sentence from my letter makes my meaning quite clear: "It is not perhaps surprising that such a minute virus . . . and one capable of withstanding complete desiccation should be present in the air."

Dr. Caldwell further says, "tobacco leaf dust contains the virus of the tobacco mosaics". Of course it may do, but this disease cannot spread in the same way, even if a suspension of tobacco mosaic virus is poured round tobacco plants growing in pots, and herein lies an interesting difference between these two viruses. Again quoting Dr. Caldwell . . . "it has not been shown that being in the air it can infect normal healthy plants"; this, of course, has been demonstrated experimentally. If a suspension of this particular virus is lightly sprayed into the air from an atomizer in the vicinity of tobacco plants growing *under controlled conditions*, a percentage of such plants is later found to contain the virus in the roots.

I take it that the main reason for Dr. Caldwell's strictures lies in his fear that my letter casts doubts on "the generally accepted view that the virus . . . is unable to enter an uninjured protoplast". If he will read my last paper[1] he will find this sentence on p. 90—"It appears therefore that some wounding must be necessary for infection, and this condition might be fulfilled by the breaking of root hairs as the root makes its way through the soil or sand". In this connexion I might perhaps mention that if a suspension of the virus is sprayed on to the leaves of French beans (*Phaseolus vulgaris*) by means of an atomizer, held at a distance of about 6 inches from the plants, numerous lesions develop on the leaves. One can of course explain this by saying that the virus is entering by broken hairs or minute wounds already existing, and this may be so, but it is a difficult point to prove or disprove.

Finally, I repeat what I said in my previous letter, namely, that the smallest quantity of virus which reaches the soil seems eventually to enter the roots of a plant growing therein, though the precise mechanism of its entry has not yet been demonstrated.

Points from Foregoing Letters

THE solubility, in water, of various dusts (such as felspar, asbestos, calcined flint) known to produce silicosis, is found by Prof. H. V. A. Briscoe, P. F. Holt, J. W. Matthews and P. M. Sanderson to be a complex phenomenon depending upon tissue, particle size, quantity of dust submitted and presence of extraneous substances. Freshly fractured surfaces of silica and certain silicates appear to be in a highly reactive state, and yield alkalis and 'soluble' silica to water to a greater extent than in the normal state. The particles lose their reactivity after a certain time, and this may explain the failure to produce silicosis in animals in experiments with 'dead' dusts.

Prof. A. Brammall and J. G. C. Leech find that many rock-forming silicates, when finely powdered, yield alkali to cold water, and several micas yield an appreciable amount of alumina on treatment with weak solutions of sodium or potassium chloride. They direct attention to the possible importance of these observations in relation to the origin and composition of sedimentary rocks.

That the ability to absorb and concentrate salts out of very dilute solutions is widely present in animals as well as plants, is suggested by Prof. A. Krogh. The mechanism involved, as indicated by Lundegårdh's experiments on plants, appears to utilize energy derived from the oxidation of sugar, and to act by transferring negatively charged (acidic) ions.

In the production of pipe and cable sheath by the continuous extrusion machine, the splitting of the lead stream by a steel part before final amalgamation results in a modification of the structure which appears as a 'line' upon subsequent deep etching. A photomicrograph of such a 'line', possibly due to small quantities of oxide or other impurities, is submitted by Dr. P. Dunsheath. The 'line' passes continuously through several crystals and, unlike the well-known defects due to a mush of small non-crystalline particles, it does not reduce the bursting strength of the pipe.

A method of measuring the magnetic moment of free neutrons is proposed by Dr. O. R. Frisch, Dr. H. von Halban, jun. and Dr. Jørgen Koch. The method consists in studying the depolarizing effect of a magnetic field on a polarized beam of slow neutrons, which is obtained by passing the neutron beam through magnetized iron, as suggested by F. Bloch. Preliminary experiments have given evidence of the existence of the depolarizing effect. The proposed method can also be used to determine the sign of the magnetic moment of the neutron.

By bombarding sodium or magnesium with fast neutrons, a radioactive substance of 40 seconds half-life period is produced which is generally assumed to be neon of mass 23. To decide whether the active substance is really a gas, Dr. T. Bjerge has applied the method of transferring the radioactive substance produced by means of a current of air, and has obtained positive results.

Dr. S. Chandrasekhar directs attention to a combination of certain 'natural' constants (the velocity of light, the mass of the proton, the constant o gravitation and Planck's constant, *h*) which has th dimension of mass. A particular form of this combination occurs in the theory of stellar interiors. B substituting simple values for the arbitrary constan in the formula, the author shows that one can obta numbers comparable with the mass of the Milky Way and with the total number of protons and/or neutron in the universe—such as were derived by Prof. Dira from similar dimensional arguments.

Commenting on sources of inaccuracy in spectr graphic research due to the influence of foreig materials in intensifying the spectrum of a give element, Dr. E. J. B. Willey points out that in so fa as the spectra are due to direct collisional excitatio the ratio of the intensities might be taken as a fa measure of the relative concentrations. But whe the radiating particle receives energy from anoth excited body, this simple relation no longer hold as shown for example by the mercury-sensitiz fluorescence of sodium.

The addition of a small amount of potassiu permanganate to water containing oospores of t onion mildew *Peronospora schleideniana* stimulat their germination if other organic matter was presen according to experiments by R. McKay. The oospor used were five-six years old and weathered out doors. Eighteen months old oospores gave no resul

Research Items

Family and Clan in Hopi Economics

MR. ERNEST BEAGLEHOLD's study of Hopi economics (*Yale Univ. Contrib. Anthrop.*, No. 15) is based on observations made in 1932 and 1934 of the culture of the two Second Mesa Hopi villages of Mishongnovi and Shipaulovi. The Hopi household, which is matrilocal and consists of father, mother, children, and unmarried or widowed brothers and sisters of the wife, is the ultimate unit of consumption and production. In marriage, both partners assume definite obligations to contribute to the economic welfare of the household; and the members of the enlarged family are brought within the partnership. A frequent cause of family quarrels is that a member is not fulfilling his economic duty. Marriage also brings together two kin groups, which then act as a closely co-ordinated unit in a number of economic activities. The clan, the maternal lineage, also has economic, as well as ceremonial duties. For example, it controls land, one of the most important items in the wealth of the community, and it is from the clan that are drawn the working parties for planting, harvesting, house-building, sheep-shearing and the like. It would, perhaps, not be incorrect to define the Hopi clan as a body of men, women and children, of common blood, periodically united for the co-operative production of food supplies and other major forms of wealth. It assumes the duties and obligations incidental to a scheme of social insurance. While the man owns only his personal effects and earnings, the woman, in addition to personal effects, if she is married, owns the house and its contents, bedding, furniture, utensils, etc. She also controls the clan lands assigned to the household. Individual ownership of lands by the male is recognized, when a man breaks in and plants land from the waste. As each household is a self-sufficing unit, specialization in economic activity, whether by individuals or by groups, is unknown.

The Nesting of Hornbills

WITH great success, R. E. Moreau has employed natives to record over long periods the feeding times of East African hornbills, and by co-operative observation he has been able to keep one nest under observation for a total of 400 hours in four successive seasons. The results present the first tolerably complete account of one of the most curious of nesting habits, and reveal unexpected differences between the three species which were studied (*J. E. Africa and Uganda Nat. Hist. Soc.*, 13, 1; 1936). For example, the sealing up of the nesting hole in the case of *Bycanistes cristatus* was done by the female, which used mud pellets elaborated in the gullet of the male and disgorged by him, whereas in *Lophoceros deckeni* the material used was collected without help from the male and consisted of insect casts and rotten wood. In the former case the male disgorged up to 2 pellets at a visit, and during a day 235 pellets in 5 visits. The daily load involves the impregnation of some 33 cubic inches of dry mud with saliva, a very considerable call upon the secretory powers of the salivary glands. The female *Bycanistes* remained sealed up in the nest for 108 days, and during that period the male made about 1,600 visits with food, carrying about 24,000 fruits. A new observation of very great interest is that in both *Lophoceros deckeni* and *L. melanoleucos*, when the female issued from the nesting hole, the young, then about three weeks old, and unable to fly, at once replaced the plaster at the mouth of the opening, without any help from the parents.

Marine Research at Port Erin

IT is satisfactory to find that, according to the Director's report for 1936 (No. 49) of the Marine Biological Station at Port Erin, Isle of Man, people are now taking a keener interest in natural history. An increase is manifest both in enthusiasm of the visitors to the aquarium as well as in their numbers. Research work in various fields is progressing, and, besides the usual staff, many visitors have been using the laboratory. Hatching of plaice and lobsters still continues, and examination of herring shoals is carried on as before. It is of interest that some adult herrings were brought alive to the aquarium and that one of them, a female, lived for eight weeks, apparently dying of starvation. A steady flow of water, pumped daily from Port Erin Bay, was maintained in the tank containing the herring. It seems that it is comparatively easy to secure the fish alive from ring trawl boats, and if the food problem could be solved it would probably be fairly easy to keep the fish alive for long periods. The report of the oyster investigations by Mr. J. R. Bruce and Dr. Mary W. Parke shows two series of experiments, in 1936, growth experiments and settlement experiments. In the first, there has been no conclusive evidence this season that any advantage is gained by using running water. In the second, from the results obtained it appears that plunger jars are the most suitable for the settlement of larvæ.

Parasitic Copepods from Belgium

J. H. SCHUURMANS STEKHOVEN, jun., continues his work on Belgian parasitic copepods ("Copepoda Parasitica from the Belgian Coast II; including some Habitats in the North Sea", *Mém. Musée Roy. d'Hist. Nat. Belgique*, Mémoire No. 74. Brussels, 1936). His material is extensive, and includes collections made under the direction of Prof. G. Gilson during the exploration of the North Sea by the Museum. A number of years is covered, and some species are represented by hundreds of specimens. Most of the species are well known, but many of the hosts are new and the geographical distribution is much extended. *Lernæocera branchialis* was available in such large quantities that a close examination of the oral parts was possible. These were chiefly on the whiting, *Gadus merlangus*, but there were also specimens on the cod, *Gadus morrhua*, and on the haddock, *Gadus aegelfinus*, whilst one full-grown female was found on the sand-eel, *Ammodytes tobianus*. The author finds that the mouth parts of *L. branchialis* differ considerably from the descriptions of Wilson (1917). The paper is illustrated by five plates of clear outline drawings.

Some Beetles of Jehol

In the report of the First Scientific Expedition to Manchoukuo, 1933, the part published in September 1936 entitled "Insects of Jehol (VI)" (Tokyo: Waseda University, 1936) deals with certain families of Coleoptera. These have been studied by a panel of Japanese entomologists who describe and figure various new and other species. Each paper is written in Japanese, and is followed by an adequate English translation. A special feature of the report is the excellence of the illustrations, the coloured plates being exceptionally well executed. Among the species figured are well-known English and other European forms, of which the range is now extended into Manchoukuo.

Gardenia Canker

Mr. W. Buddin and Miss E. Wakefield direct the attention of gardeners to a canker disease of gardenias caused by a fungus belonging to the genus *Phomopsis* (*Gard. Chron.*, April 3, 1937, pp. 226–27). Canker may occur upon the stem, below ground-level, or it may appear if any 'snags' are left when the blooms are removed. The disease has appeared previously in Great Britain and in the United States, but it is reassuring to find that the present outbreak is not of serious proportion. Control of the disease appears to be effected if old cankered plants are burned, and cuttings are taken only from uninfected material.

Elastic Properties of Selenium

Work carried out during the last two or three years has shown that the elastic properties characteristic of rubber are associated with the existence of the substance in the form of long chain molecules. These have been shown to occur in filiform sulphur and in polyphosphonitrilic chloride $(PNCl_2)_n$, which has been described as an inorganic rubber. K. H. Meyer and J. F. Sievers (*Naturwiss.*, 25, 171; 1937) have now shown that amorphous selenium, when heated to 70°, possesses elastic properties. If the threads are rapidly stretched and allowed to contract at ordinary temperatures, they become crystalline, but the substance becomes elastic once more on warming to 72°. Selenium possesses, in the crystalline state, the necessary chain-like arrangement of atoms.

Structure of Polished Metal Surfaces

According to the ideas first put forward by Beilby, polish on a metal surface consists of an amorphous layer of 'flowed' metal. Several attempts to investigate this layer have been made using electron diffraction, and while the experiments support the idea of an amorphous layer, there have been difficulties in their interpretation. In particular, the diffraction rings observed seem to have much the same size for all the metals examined. S. Dobinski (*Phil. Mag.*, March) points out that the process of polishing in air is likely to lead to the formation of an oxide layer. He has therefore ground and polished specimens of metal under benzene or pentane and transferred them, still wet with the liquid, to an electron diffraction camera which was at once evacuated. Diffuse haloes were observed in the diffraction pattern, showing that an amorphous layer was present, but the spacing of the atoms was in most cases appreciably different from that observed in specimens polished in air. The layer is apparently close-packed, with an atomic separation approximately the same as that in the crystal lattice of the metal in question, and differing considerably from metal to metal.

Photo-Decomposition of Acetone

In certain circumstances acetone vapour has been found to decompose on absorption of ultra-violet light with the production of equal volumes of ethane and carbon monoxide. Hence the primary reaction is formulated as: $(CH_3)_2CO + h\nu = 2CH_3 + CO$. It is now shown by R. Spence and W. Wild (*J. Chem. Soc.*, 352; 1937) that, in the circumstances in which they worked, the value of the C_2H_6/CO ratio at room temperatures is 3/2, both in presence of hydrogen and with pure acetone. Diacetyl was found to be produced in considerable amount and they bring forward evidence that the primary decomposition is into the methyl and acetyl radicals: $(CH_3)_2CO + h\nu = CH_3 + CH_3.CO$. The composition of the products was found to depend largely on the experimental conditions. The presence of free methyl radicals (which is required by both alternative equations) has been well established. It is suggested that light absorption in the banded region leads to the production of an excited molecule which may dissociate directly into ethane and carbon monoxide without the intervention of radicals. The effective life of the acetyl radical decreases rapidly with rise in temperature, and increase of acetone pressure or decrease of light intensity increases the proportion of methane in the products at 60°, owing to the occurrence of the reaction: $CH_3 + (CH_3)_2CO = CH_4 + .CH_2.CO.CH_3$.

Railway Traction Problems

This is the title of an article by Lord Monkswell which appears in *Discovery* of March and in which the author discusses some of the present-day problems of railway transport. The resistances due to gravity and acceleration are invariable and easily calculable. The author is more concerned with the resistances, referred to as irreversible, such as friction, or only partly reversible, as the compression of the rail-bed. In well-lubricated axle-boxes, friction is inconsiderable, but when bogies and axles require to adjust themselves to curves it is perceptibly increased. In the steam locomotive itself, owing to the number of parts having reciprocating motion under heavy pressures, friction has to be reduced by the most efficient means of lubrication and by the use o metallic packings with lateral self-adjustment. The greatest possibilities of improvement are associated with the reduction of air resistances, but there is as yet, little accurate knowledge on this subject The practical value of stream-lining at speeds less than 50 miles per hour is problematical, but where it has been adopted on trains of higher speed the results have been beneficial. The author, however expresses doubt as to the validity of the extent o the advantage claimed in some cases. On the subject o engine performance, some figures are given—notabl those relating to that of a reconstructed locomotive o the Chemin de Fer du Nord when hauling a train o twelve vehicles weighing 559 British tons. It was abl to maintain an average speed of 66 miles an hour for length of 14 kilometres on the Survilliers bank gradient 1 in 200 to 220, a performance representin about 32 h.p. developed per ton weight of locomotiv Although higher values have been obtained, it regarded as improbable that so high a figure h been maintained over the same length of time.

International Association for Testing Materials

LONDON CONGRESS

IN opening the Congress of the International Association for Testing Materials at the Institution of Civil Engineers on April 19 and in welcoming the visitors from abroad, Sir William Bragg suggested that the name did not quite fully convey the extent of the Association's work and interests, which include the investigation of the nature and properties of materials and make use of the whole range of available methods, from the most highly scientific to those which are entirely empirical. This is well illustrated in the range of papers which have been presented by prominent workers in this exploratory field and engaged in most, if not all, of the twenty-five countries which were represented at this meeting. The function of the Association is to secure international co-operation and an exchange of views, experience and knowledge in regard to materials and their testing. As has been pointed out by Dr. H. J. Gough, chairman of the British Committee responsible for the arrangements, the achievements of this age of great scientific and technical development owe much to the present-day knowledge and skilful use of the properties of materials. Direct application of these are of prime importance in transport, power generation and supply, construction, inter-communication and even in some forms of entertainment. Further, the study of existing materials leads to the production of new and improved materials, and it is this study which the Association promotes and, by means of such as the present Congress, the results and ideas are discussed. Once entirely empirical, the study of materials is now developing along lines of scientific method and, in due course, may become established as a true science.

In connexion with this meeting, an exhibition of testing plant and apparatus was arranged; manufacturers of the instruments and machines used in this class of work have collaborated with the organizers in showing their most up-to-date and reliable products. Although described as limited in size and scope, the range and comprehensiveness are remarkable, so that only a few of the most recent apparatus can be referred to in detail.

Refractory laboratory ware in alumina, now manufactured in England, is suitable for temperatures up to 1,950° C. for the fusion of metals, alloys and alkalis, and is highly resistant to the action of fuzed metals, oxides, salts and acids, while its high electrical resistance makes it eminently suitable as an insulator at high temperatures. The possibilities of the practical applications of the fluorescence test in food testing, police work, banking, philately—to take just a few random cases—are indicated by the useful types of lamps made by several firms. The Smith wear and lubricant tester is a new type of machine using a steel ball as the active member and its worn impression on the sample as the means of measurement. The cement-testing pistol makes a ball impression by a blow on the surface of the standing cement, and is claimed to give a measure of the compressive strength. For the rapid and accurate estimation of the specific gravity of gases, the new type of balance devised by Messrs. Hales and Moss, of the Fuel Research Station, is of particular interest. It operates by measuring the loss of buoyancy of an air bulb in an atmosphere of the gas in question. The Griffin Gale testing machine enables tensile, compression, indentation and bending tests to be carried out on small samples of metals and other solid materials. In the same class is the Hounsfield tensometer, while the Quinney autographic testing machine is of larger scale and gives load extension diagrams recorded by a pointer moving on smoked glass. Several firms engaged in research exhibited apparatus devised for their own work, among them Metropolitan-Vickers Electrical Co., Ltd., which has an apparatus for detecting conducting particles in textile sleeving, a magnetic crack detector and a dilatometer for determination of coefficient of expansion. In addition, the Department of Scientific and Industrial Research arranged a special section illustrative of apparatus and methods used in the laboratories co-operating in this congress.

As regards the papers presented at the Congress, most of them were available in advance; the accounts which follow were prepared from such advance proofs.

GROUP A (METALS)

The 77 papers in the Metals Group were sub-grouped under four headings: (1) Behaviour as dependent upon temperature; (2) progress of metallography; (3) light metals and their alloys; and (4) workability and wear.

In Sub-Group 1, the mechanism of the creep of metals and creep testing methods receive considerable discussion. H. J. Tapsell (National Physical Laboratory) directs attention to the phenomenon of creep recovery, a continuous contraction after unloading, which may continue in certain cases for thousands of hours after the release of stress. Two possible hypotheses are put forward, and it is considered that the study of creep recovery should assist in furthering the knowledge of the nature of creep. Dr. C. L. Clark and Dr. A. E. White (University of Michigan) summarize two theories concerning the mechanism of creep, on the basis of which the known influences of a number of factors on creep resistance can be readily explained. Dr. A. Nadai briefly surveys the results of work at the Westinghouse Laboratories, and emphasizes, among other things, that methods are needed in industry to shorten the time of creep tests from a duration of three months or more to times of the order of hours or days; these must be based on a better knowledge of the speed law connecting stress with strain rate.

Dr. U. R. Evans discusses corrosion as influenced by increased temperature, pointing out that at high temperatures the rate of combination between metallic atoms and oxygen atoms is very rapid, and the rate of wastage of metals exposed to hot oxidizing gases is usually only limited by the rate of penetration of oxygen inwards through the oxide-coat, or by the rate of diffusion of metal outwards to the oxygen. The testing of high endurance oxidation-resistant alloys is described by F. E. Bash, of the Driver-Harris Co., New Jersey. Improvements in these materials have greatly increased the difficulty and the time required in their testing; the present test temperature, 1,175° C., is 110° C. higher than that originally standardized, but wires last as long to-day at this temperature as was the case formerly with the lower temperature.

In the sub-group on the progress of metallography, the papers were again classified into sections on micrography, X-ray interference, electron diffraction and emissivity, equilibrium diagrams, non-metallic inclusions, solidification of ingots and recrystallization.

W. H. Dearden (University of Bristol), contributes a valuable survey of recent progress in the preparation of specimens for macro- and micro-examination, with a very full bibliography on etching reagents, and Dr. A. J. Bradley gives an account of the development of quantitative metallographic X-ray methods. Dr. H. J. Gough summarizes the results of his extensive study of the mechanism of deformation and fracture in metals, while Prof. G. I. Finch, in a paper on electron diffraction in the study of metal films and surfaces, emphasizes that the realization of the full advantages of electron diffraction and of the older methods must lie in their future co-operation. Dr. W. Burgers describes the method of electron-optical observation of metal surfaces. This method permits of the study of phases which are stable only at high temperatures, and of the direct observation of transition and recrystallization processes.

In a paper on "The Solidification of Ingots", Dr. C. H. Desch ably summarizes the somewhat conflicting views of various workers on the causes of inverse segregation.

The Sub-Group concerned with light metals and their alloys contains several papers of a more practical nature. Dr. A. G. C. Gwyer and Mr. H. G. Dyson report recent progress in aluminium casting alloys, and emphasize the increasing use of heat-treated alloys and of grain-refining additions such as titanium. Progress in this sphere in America is summarized by E. H. Dix and Zay Jeffries, while Dr. G. Siebel reviews improvements in magnesium alloys leading to increased resistance to corrosion. Dr. J. L. Haughton describes recent work at the National Physical Laboratory on the development of new magnesium alloys, particularly those containing aluminium and silver, and cerium, cobalt and manganese, which have improved physical properties.

GROUP B (INORGANIC MATERIALS)

Inorganic Materials (Group B) constitute a most interesting section, not only on account of the intrinsic importance of the cements, stones and ceramic materials which it includes, but also because the methods of testing are in a state of active development. Although these materials are in quite a different class, the methods of testing have been, in the past, greatly influenced by those devised and used for the ductile materials. The proceedings of the Conference may therefore be generally looked to for information as to the tests and procedure which are being found most practicable and reliable.

One of the difficulties met with in carrying out tests is the time required for the materials to mature or 'age', and a typical paper is that in which A. Brund (Härnösand, Sweden) submits the results of tests hastened by means of electric heating. Heat is generated in the paste by alternating current, and thereby accelerates the reaction between water and cement. The resistance is found to decrease during the first period of hardening, reaching its minimum as binding begins and increasing during the later period of hardening. It is claimed that the heat development and curing automatically regulate one another, thus ensuring uniformity of hardness throughout the specimen and a smaller amount of variation in the test results. Variations arising from the personal element introduced in mixing, mould filling and compacting are also a source of difficulty in standardizing tests, and the improvement in this respect effected by the use of a high-frequency vibrator, and the several steps and reasons which led to the use of this machine, are described by Dr. W. H. Glanville (Road Research Laboratory, Harmondsworth). In several papers, suggestions are put forward recommending variations which have been made in laboratory technique and found satisfactory.

Several reports of studies on the control and measurement of the heat of hydration of cements in large masses are presented. Dr. F. M. Lea (Building Research Station, Garston) discusses the merits of the present methods of measuring its value. The 'heat of solution' method is the calculation of the difference of the values for hydrated and unhydrated cement in a nitric-hydrofluoric acid solvent. The adiabatic calorimetric method, in which the samples are stored so that no heat is lost and the temperature therefore rises in proportion to the heat evolved by the hydrating cement, is considered to be more reliable. In "Methods of Testing Cements for Large Dams", B. Hellström, judging from comparative tests carried out at different laboratories in England, Sweden and Norway, regards this latter test as sufficiently accurate for adoption as a routine method. Dealing, on the other hand, with the control of this heat, P. H. Bates (U.S. National Bureau of Standards) directs attention to three different methods by which cements of low heats of hydration can be produced, the first and most usual being to effect a change in composition in one of several possible ways, the second being a process of preheating the clinker, and the third depending upon a system of partial pre-hydration in an atmosphere of steam at 212° F. No very definite data are, however, available as to the relative merits of these methods.

Numerous issues are raised in connexion with the action of different qualities of water on cement which is immersed, and several of the contributors deal with one or other of these. In describing some properties of *ciment fondu* and, in particular, its resistance to the action of soft waters, E. Rengade advances the view that the chemical resistance of a mortar is not necessarily directly related to the solubility of its individual constituents, but depends upon the manner in which these are arranged in the heterogeneous mass of which it is composed. Prof. G. Batta (University of Liège) submits some notes on several causes of disintegration, including solubility of constituents and attack by sea-water and by sulphated waters, this last case also being dealt with by G. Baire (Boulogne-sur-Mer Cement Laboratories) in a paper in which he gives the results of mechanical tests on specimens treated with solutions of the sulphates of magnesia and lime.

On the mechanical side, there are several papers devoted to testing, to the value of vibration as a means of compacting and improving the strength of the mixtures and to the grading and workability of aggregates. In his paper, Dr. Glanville sets out a concept of the term 'workability' as a physical property of concrete, and explains its measurement by analysis of the applied work, the useful work and the useful internal work done on a mix, and by the introduction of a compacting factor to define the degree of freedom from air voids at each stage. Considerable interest is attached to a group of papers dealing with the influence of the compressive strength of concrete in relation to the yield point of steel on the degree of safety of beams, particularly those presented by Prof. Rudolf Saliger (Vienna) and by F. G. Thomas (Building Research Station, Garston). In this section, too, a prominent feature is the analysis by Prof. M. Roš (Zurich) of the stresses and deformations produced in cement pipes by internal and external pressures and by bending moments such as may be imposed upon them.

GROUP C (ORGANIC MATERIALS)

In Sub-Group 1 (Textiles), an extensive review of chemical tests at present applied to textiles as well as to accessory materials such as oils, sizes and wetting-agents, is given by Dr. H. Phillips, while B. H. Wilsdon provides a similar summary of mechanical tests. Among individual tests, determination of resistance of fabrics to wear is critically examined by R. Severi, who proposes the use of the fabric itself as an abrasive, and by Dr. F. Maillard, who maintains the desirability of abrading the fabric on both sides. Methods for measuring the fastness to light, washing and perspiration of dyed textiles are described by W. D. Appel, whereas a method for determining the fading of dyes and pigments, claimed to give reproducible results independent of the observer, is put forward by R. Toussaint. The detection of damage, especially of a chemical nature, produced during finishing of artificial silk, is discussed in considerable detail by W. Weltzen. Means of assessing the resistance to anærobic bacterial attack of textiles used for building and insulating purposes are described by Dr. J. P. Pfeiffer and H. Eilers. An accurate calorimetric method for determining cotton present in asbestos yarn is proposed by Dr. R. de Benedetti.

Sub-Group 2 (Wood Cellulose) consists of nine papers by authors representing six separate countries.

Cellulose has not yet been isolated as an absolutely pure chemical individual, but it has been established that the celluloses from all known sources have certain well-defined constitutional and structural factors in common. Dr. De Witt Smith (U.S.A.) points out that a wide gap exists between our know-edge of the cellulose molecular chain and the fibril, which latter is large enough to consist of several million molecular chains side by side. This gap has been bridged to some extent by the discovery that fibrils can be broken down to smaller units which have been variously named 'dermatosomes', granules', 'crystals' and 'fusiform bodies'. These maller units appear to be held together in the fibril by a cementing material of a pectic nature.

So far as wood cellulose is concerned, W. G. Campbell (Great Britain) indicates that the chief onstitutional point at issue is the relationship etween that portion which consists of anhydrolucose residues and the remainder. The suggestion i advanced that, although immediately after forma- on all celluloses may be chemically identical, their espective constitutions may be modified by purely hysiological agencies which may vary from species o species in the plant kingdom or even from organ to organ in the same species. A second paper on wood cellulose by Dr. Forster (Great Britain) is to be published in the Congress book. Prof. H. Mark (Austria) discusses the present position regarding the influence of fine structure on the properties of artificial fibres. Although artificial fibres, the properties of which emulate those of the natural fibres, have been prepared, research is still required in order to establish all the conditions necessary for the attainment of consistently reproducible results. Dr. G. Hostomský (Czechoslovakia) describes the Hoeppler viscosimeter and discusses its application to the control of rayon pulp manufacture. Four papers by Prof. G. Jayme (Germany), D. Johansson (Sweden) and L. G. Cottrall (Great Britain) respectively, offer a comprehensive review of current practice in the testing of pulp and paper.

Sub-Group 3 (Timber Preservation) consists of ten papers dealing with the structure, mechanical properties and preservation of timber. A. Nowak (Austria) mentions recent successful moisture proofing of plywood, etc., by impregnation with wax dissolved in an organic solvent, the solvent being afterwards recovered. Owing to the use of creosote for other purposes, many countries are turning to oil emulsions and water-soluble salts for preserving timber against decay. Leise (Germany) further describes the use of water-soluble salts, and mentions the development of the bichromate mixtures which, by depositing insoluble compounds in the wood, are rendered highly resistant to leaching. The lack of a uniform practical definition for the fire resistance of wood is mentioned by E. Azzarello (Italy), who describes four tests which he has adopted for inflammability, flame propagation, flame penetration and rapidity of carbonization. A. Breazzano (Italy) describes a laboratory toxicity test for wood preservatives in which thin samples of wood soaked in the preservative solution are placed in large tubes, and a small piece of active inoculum attached to one face of the sample. The toxicity of the preservative is measured by the minimum concentration which will prevent the hyphæ passing through the thin slip of wood and showing on the opposite face. The author claims that this method gives maximum accuracy and much quicker results than the method adopted at the Berlin Conference in 1930.

The use of large wooden beams built up of pieces of relatively small dimensions is an increasingly important aspect of wood utilization. P. T. Landsem (U.S.A.) describes the properties of such beams and quotes the efficiencies of the various types of connexions. Using the modern type of ring shear connectors, it is possible to obtain an efficiency of 95 per cent, whilst beams built up of laminations placed horizontally and glued together are easily made stronger and stiffer than equivalent solid beams by proper selection of material.

Products discussed in Sub-Group 4 (Ageing of Organic Materials) comprise hydrocarbon oils, bitumens, rubber and some textiles. Methods of following the course of oxidation of mineral oils in general are discussed by Dr. G. Barr, while the detection of ageing in oils and bitumens used for special purposes, chiefly lubrication and insulation, is dealt with by Dr. F. Evers and by Dr. H. Stager. Rapid methods for testing the physical properties of asphalts and bitumens are described by Prof. R. Matthis, who also proposes the use of *p*H determinations for testing the ageing of materials soluble in or extractable by water. The causes, effects and methods of detection of ageing in vulcanized rubber are brought under review by B. D.

Porritt and Dr. J. R. Scott. Methods used in the United States for testing ageing of rubber, paper and silk are described by W. E. Emley. The testing of road tar is discussed by G. Batta and that of asphaltic bitumens by Dr. J. P. Pfeiffer and R. N. J. Saal.

A general tendency towards elimination of the personal factor in testing is discernible in Sub-Group 5 (Colours and Varnishes), as may be seen from the general review by Dr. L. A. Jordan of methods of assessing behaviour of paint films in practice, and the description by Dr. E. Rossmann of test methods used in Germany. An apparatus for measuring the fastness of colours to soap solutions, water and perspiration, also designed to eliminate the personal factor, is described by W. Kaczkowski, while Prof. A. R. Matthis puts forward a simple and rapid method of measuring fluidity of oils such as are used in the paint and varnish industry. The corrosive action of insulating varnishes on copper receives attention in a paper by Dr. G. Rossi. Theoretical considerations of the effect of oxidation, polymerization and addition of plasticizers on the molecular structure of oil films are made use of by Dr. A. V. Blom to explain the effect of such agents on the mechanical properties of the paint and varnish films afterwards produced. A plea for more rational terminology in the industry is brought forward by H. Rabaté.

GROUP D (SUBJECTS OF GENERAL IMPORTANCE)

The papers comprising Group D of the Congress are described as covering "Subjects of General Importance". They actually fall into three sub-groups: (1) the relation between the results of laboratory tests and behaviour in use and service; (2) the bearing of recent advances in physics and chemistry on the knowledge of materials; and (3) the properties of materials for the thermal and acoustical insulation of buildings.

The papers under (1) deal in a general way with problems which are more fully discussed in other sections, in relation to specific materials. The reviews of testing methods do not bring anything new before the Congress, but three papers, which from their titles may raise more important questions, have not been received in time for printing in advance. A paper by Sir Robert Hadfield and S. A. Main directs attention to the impossibility of imitating service conditions exactly in any laboratory test, and to the fact that most such tests are really designed to ensure that a given material conforms to a standard which has been found in practice to be satisfactory. It is pointed out that there is still no satisfactory means of determining resistance to abrasion, or the wearing quality of cutlery, whilst the behaviour of such parts as the pistons and piston rods of steam and pneumatic hammers under repeated shock is still imperfectly understood. Accelerated tests for resistance to corrosion are also very uncertain in their indications. M. Roš deals with the general question of factors of safety, giving values for a number of concrete instances.

Sub-Group 2 includes, besides several papers of a general character, an account of the methods to be adopted in testing for flaws in metals by means of gamma rays, by F. Guyot, and a short comparison between the methods of testing by X-rays and by radium, by Dr. V. E. Pullin. A. Pogány describes the study of the propagation of cracks in such masses as cement or concrete while under load in a testing machine by means of a microscope employing vertical polarized light. The gradual separation of the grains of sand from the matrix in a cement briquette can be clearly followed in this way. Sir Gilbert Morgan and his colleagues review the principal types of plastic materials of chemical origin, including synthetic resins and rubber-tar products, together with an account of the improvement of tar for road purposes by adding to it a calcium soap. The equations which have been proposed to describe the flow of dispersed systems are surveyed by M. Reiner.

The third sub-group is more homogeneous. The problems of insulating buildings against heat and sound are closely related, although the best materials for the one purpose are not necessarily the most suitable for the other. Several papers deal with the practical methods of studying the efficiency of different means of insulation against sound, particulars being given of the laboratories at Brussels, Berlin, Stockholm and Teddington, whilst P. Sabine, of the Acoustics Laboratory at Geneva, Ill., in describing the methods adopted by the American Standards Association, urges a careful standardization of test procedure among the various laboratories which are co-operating in this field. It is desirable that, by applying a correction factor to the results from any given laboratory, comparable figures should be obtained from which coefficients of wide practical applicability can be derived. Porous materials, such as slag or glass wool or various organic fibres, are used for both thermal and acoustical insulation, as is a construction consisting of sheets of solid material separated by air spaces. Dr. E. Griffiths refers to the use of lightweight concrete, made by mixing with the cement some substance which can cause the evolution of a gas and the production of a stable foam. With such an aggregate as pumice, foamed slag, or expanded slate, a very light concrete of open texture is obtained, with fair mechanical strength. The subject of protection against noise is one of public interest at present, and this series of papers provides much useful information concerning it.

Heredity versus Environment

IN a paper recently presented before the Eugenics Society, Dr. David Forsyth returns to that interminable argument 'Heredity *versus* Environment'. By him, heredity is taken to imply transmission from one generation to another, this transmission comprising structural and functional tendencies to develop organic life. By environment he understands the conditions around an organism. He has bee examining the commonly accepted view that heredit and environment play indispensable parts in development, and that each operates separately from th other, and now finds it quite impossible to entertai this view any longer.

If, Dr. Forsyth argues, heredity and environmen are indeed independent of each other, then it shoul be possible logically to trace the extent of the spher of influence of each, their influences should be detectable separately, and their origins should be differen If this should prove on examination to be impracticable, then it must become necessary to jetison th present-day concept of heredity and environment being two discreet forces, and to replace this b another more in harmony with the facts. If, as done nowadays, heredity, as a term, is applied onl to the germ cell and to what that cell comprises at the moment of fertilization, all factors outside this fertilized ovum which may affect it being regarded as environmental, then, as Dr. Forsyth proceeds to show, the use of these terms quickly leads into error.

The fertilized egg, with its chromosomes and genes, has long been residing within its environment: the maternal body. It grows and differentiates, and soon, within the embryo that evolves, the gonads appear. These have now a multiple environment: the embryonic soma, the maternal body and the outside world. It is taught that the embryo's body is hereditarily derived, whilst the mother's is environmental; but, according to this argument, there must have been a time when the mother's body itself was the product of inherited factors exclusively, so that what was heredity at one time is now environment! The terms are apparently interchangeable, and therefore lose their distinctiveness. Then again, the embryo, just as do the chromosomes and genes themselves, grows because nutriment of every kind passes into it from its outer world. Thus the embryo itself must necessarily be a compound of heredity and environment, the two so inextricably intermingled that it is beyond our powers to disentangle them. This division of heredity and environment is purely hypothetical and artificial, and, Dr. Forsyth maintains, lacks experimental confirmation.

Dr. Forsyth then proceeds to argue that an environment itself can be inherited. The character of an individual is deeply moulded during early childhood by its parents. The latter are environmental influences. The characters of these parents were, in turn, largely fashioned in their childhood by their own parents; and these by theirs. Dr. Forsyth asks if this is not an instance of the transmission of hereditary psychological qualities. If so, then the moulding of a child's nature by its parents is environmental only when its own generation is taken into account, and, from the wider view of successive generations, it is hereditary.

These extracts, taken from Dr. Forsyth's paper, may serve to show that what he has to say must necessarily be of interest to the philosopher. The biologist, and especially the geneticist, will be provoked to wonder how Dr. Forsyth's difficulties arose. It is clear that they have their origins in the definitions he employs and in his lack of contact with experimentation. Did he but seek his solutions in the laboratory rather than in the library, he would quickly persuade himself that it is eminently possible to disentangle genetic and environmental forces and to study them separately. To all intents and purposes it is possible to stabilize and standardize the environment and, in this, examine the effects on development of different genes and, by using genetically identical individuals, to study the effects of different environmental factors. It is impossible to deny the facts revealed and abundantly confirmed by genetic experimentation, or to disregard the firm conclusions which have been built so carefully upon them. There is no real conflict between the hereditarian and the environmentalist: each is right and both are wrong, for the simple reason that without an environment there could be no expression of genetic potentialities, and, in the absence of the power to become, no environment can evoke anything. Nevertheless, though the two are at all stages of the individual's development so interwoven, it is possible, by appropriate experimentation, to separate them and to study each alone.

Science News a Century Ago

The Royal Institution

ACCORDING to the *Gentleman's Magazine*, the anniversary meeting of the Royal Institution was held on May 1, 1837, the Duke of Somerset, president, being in the chair. "The report of the visitors announced that, after a long season of difficulty, the Institution was now placed in that independent station, which as the most active and popular establishment in the Empire, adorned with the celebrity imparted to it by more than one great philosopher, it ought always to have occupied. The whole of the debt had, during the past year, been cancelled, and a balance now existed in favour of the Institution. The premises were in a state of substantial repair, and the visitors expressed a hope for the speedy accomplishment of the proposal of giving to the exterior of the building an appearance more in accordance with the importance of the scientific body to which it belongs. The thanks of the meeting were voted to Mr. Faraday, for his devotion and services to the interests of the Institution, and the usual ballot for officers took place."

Power of Galvanism

THE issue of the *Dublin Journal of Medical Science* of May 1, 1837, contains the following note. "A paragraph is going the rounds, said to have been extracted from a late foreign Journal, but which, however, we cannot find in any of our exchange favours, which describes the restoration of speech, taste and hearing in a Polish officer who had been deprived of them ever since the battle of Ostrolenka in consequence of an unsuspected discharge of cannon. The concussion was so tremendous as to throw him down; and although there was not the slightest external wound, when he recovered himself he found that two of his senses, viz., taste and hearing, as well as the power to articulate words, were completely gone. All the eminent physicians of Vienna had made trial of their skill to restore the loss, but ineffectually. Being finally conveyed to Paris, the advice of M. Magendie was sought. He applied the galvanic fluid to the tympanum, and by that means speedily overcame the deafness."

Lyell and his "Principles"

WRITING to his sister on May 3, 1837, about his book "Principles of Geology", which had appeared during 1830–33 in three volumes, Lyell said: "I have at last struck out a plan for the future splitting of the 'Principles' into a 'Principles' and 'Elements', as two separate works, which pleases me very much, so now I shall get on rapidly. The latest news is, that two fossil monkeys have at last been found, one in India contemporary with extinct quadrupeds, but not very ancient—Pliocene perhaps—another in the South of France, Miocene and contemporary with Paleotherium. So that, according to Lamarck's view, there may have been a great many thousand centuries for their tails to wear off, and the transformation to men to take place."

William Henry Barlow on Lighthouse Illumination

ON May 4, 1837, Peter Barlow (1776–1862) communicated to the Royal Society a paper he had received from his son William Henry Barlow (1812–1902) entitled "On the Adaptation of Different Modes of Illuminating Light-houses, as Depending on their Situation and the Object contemplated in their Erection". The paper was contained in a letter sent from Constantinople on March 14, 1837. The younger Barlow had been trained as an engineer at Woolwich Dockyard, and in 1832 had been sent to Turkey by Mandslay, Sons and Field, to erect cannon-boring machinery, and had then been employed by the Turkish Government on the erection of lighthouses at the Bosphorus entrance to the Black Sea. The object of his paper was to investigate the principles on which the illuminating power, resulting from the employment of reflectors and of lenses, depends. He had arrived at the inference that the advantage gained by the employment of lenses does not arise from their superior perfection as optical instruments, but from their using the light more economically, in consequence of their producing less divergence of the rays both horizontally and vertically, and illuminating a much smaller space on the horizon.

Peter Barlow was for forty-one years professor of mathematics at the Royal Military Academy, Woolwich; his son became famous as a railway and bridge engineer, and was one of the committee appointed to consider designs for the Forth Bridge.

The Worary Poison

At a meeting of the Medico-Botanical Society on April 26, reported in *The Lancet* of May 6, 1837, Dr. Hancock showed specimens of the worary plant gathered from the mountain Courantine on the Rio Parime, with a bundle of arrows poisoned thereby. Dr. Hancock said that worary was undoubtedly a species of *Strychnos*, although its flowers had never been seen by any botanist. The poison was put up in small gourds or fruit capsules of the worary plant, and the arrows were propelled by blowing them through a reed formed of a slender spike of palm. Divers false reports had been published with regard to the manner in which the poison was prepared and its toxicological effects on the animal economy. Many native charlatans living near the settlement made Europeans believe that it was formed of a great variety of substances, such as pepper, serpent's teeth and other such ingredients. The genuine poison, however, was undoubtedly prepared as an extract formed solely from the bark of the plant. Its mode of action was curious, for though when introduced into the blood it soon became fatal, when taken into the stomach, it produced no sensible effect, in which respect it differed from every other species of the *Strychnos* family.

United Service Museum, Whitehall

The *Gentleman's Magazine* of May, 1837, gives the following account of the activities of this museum at that date: "Dr. Ritchie has begun a series of lectures on experimental Philosophy—the properties of matter—statics, mechanics, strength of materials, laws of motion, hydrostatics, etc., and Dr. Lardner is delivering others on the particular subject of steam communication with India.—Captain Norton, late of 31st regt., is also about to discourse on rifles, shells and sundry modern projectiles, with some remarks on the Boomerang, or New Holland spear, and on the ancient Balista. . . . . Already has the Museum acquired respectable funds from which it is proposed by the Council to found a permanent Professorship for the instruction of the members in mathematical and experimental science."

University Events

Belfast.—Dr. J. H. Biggart, at present lecturer in neuropathology in the University of Edinburgh, has been appointed to the Musgrave chair of pathology as from October 1 next.

Birmingham.—Prof. L. G. Parsons has accepted an invitation to deliver the opening address at the annual meeting at Niagara Falls, Ontario, of the Canadian Society for the Study of Diseases of Children, and Prof. H. Beckwith Whitehouse, of the Department of Gynæcology, is to represent the British Medical Association at a conference at Ottawa in June next.

Cambridge.—It is recommended that the degree of M.A., *honoris causa*, be conferred upon Colonel F. J. Hayter, honorary keeper of the Australian and Fiji Collections at the Museum of Archæology and of Ethnology since 1928.

The Linacre Lecture will be delivered by Prof. A. V. Hill, Foulerton professor of the Royal Society, on May 10, at 5 p.m., in the lecture room of physiology. The title of the lecture will be, "The Heat-Production of Muscle and Nerve: A Critical Survey".

Oxford.—Prof. T. G. B. Osborn, of the University of Sydney, has been appointed Sherardian professor of botany, as from October 1 next (see p. 746).

Dr. J. L. Stocks, vice-chancellor of the University of Liverpool, has been elected an honorary fellow of St. John's College.

Societies and Academies

Dublin

Royal Irish Academy, March 16.

J. J. Dowling and T. G. Bullen: Precision measurements with a radial deflection oscillograph. The cathode beam is caused to revolve in the annular space between an extra pair of concentric conical electrodes in a modified cathode ray oscillograph. Two applications are specially considered. Using a double frequency synchronized circular time-base, the radial deflection results in a limaçon-like curve. This was employed to measure instantaneously small variations in the radio-frequency of the Droitwich carrier-wave during the U.R.S.I. emission of March 1935. The use of high-speed spiral time bases in 'comparator' measurements of long time intervals (Nature, 137, 279; 1936) is also dealt with in detail. Preliminary results indicate that the difference in the periodic times of two two-second pendulums can be determined to one tenth microsecond in an experiment lasting less than half a minute. The method is being applied to the measurement of the gravitational attraction constant *G*.

Paris

Academy of Sciences (*C.R.*, 204, 925–1016; March 22).

Henri Lebesgue: A construction of the regular polygon of 17 sides due to André Marie Ampère, from some documents preserved in the archives of the Academy of Sciences.

Charles Achard, Augustin Boutaric and Mlle Suzanne Thévenet: Viscosimetric researches on solutions of the various proteins of the serum.

Jules Haag: The theory of oscillations of relaxation.

Dimitri Riabouchinsky: Some remarks on the vortex theory of the helix.

Jacques de Lapparent: The kaolinites capable of being rendered active.

Henri Lagatu and Louis Maume: The agricultural interest of the separate measurement of the nutritive effect and the improving effect of an addition of manure.

Claude Chabauty: Series of powers with p-adic coefficients.

Paul Lévy: The arithmetic of the laws of probability and the finite products of Poisson's laws.

Mlle. Britt Ranulac: The derivability of certain functions represented by an integral.

Karl Menger: A new demonstration of the Euler-Lagrange equation.

Chi-Tai Chuang: A theorem relating to the directions of Borel of meromorph functions of finite order.

Albert Toussaint and Svetopolk Pivko: An approximate method of calculation of infinite multiplane cells in plane stream.

Paul Dumanois and Georges Desbrosse: The classification of heavy combustibles. The relation between the ketene number and the delay in ignition.

Henri Grouiller: The light variations of Nova Lacertæ, 1936. A curve is given based on 810 observations made by twenty-five observers,. This nova can be classified definitely in the group II*a* (flash novæ properly so-called).

Mlle. Paulette Février: The general form of the definition of a logical system.

Francis Perrin and René Lucas: The mechanical actions of elastic thermal waves of liquids.

Jean Roig: Electrical and optical measurements on the illumination of helium in the high-frequency discharge.

Raymond Zouckermann: Curves of explosive potential in the case of ionization by collision of the second kind.

Henri Triché: A method of studying the corrosion of alloys. By means of the high-frequency spark, extremely thin layers of metal can be analysed: advantage is taken of this to study the composition of the surface layers of an alloy after corrosion by a reagent.

Mlle. Marguerite Quintin: The hydrolysis of copper benzenesulphonate.

Stefan Procopiu and George Vasiliu: The torsion of an iron or nickel wire facilitates discontinuities of magnetization with an axial alternating current.

Serge Nikitine: Theoretical considerations on photodichroism (Weigert effect).

Salomon Rosenblum and Marcel Guillot: Certain regularities in the nuclear levels of radioactive atoms.

Mlle. Jeanne Foret: The synthesis under pressure of the hydrated calcium silicates.

Léon Malaprade: The existence of crystallized cupriperiodates.

R. Michaud and E. Segol: The recrystallization of aluminium-magnesium alloys.

Mme. Yvonne Khouvine: The reduction of α-*d*-glucoheptulose by Raney nickel.

Raymond Calas: The preparation of camphorone and of two stereoisomeric dihydrocamphorols.

Max Mousseron and Robert Granger: Some cases of reduction caused by organomagnesium compounds.

Charles Prévost and Joseph Wiemann: The halogen-argento-benzoic complex compounds. Bromine and chlorine react with silver benzoate like iodine, and the complex compounds formed possess properties very similar to those of the iodine compounds already studied.

Louis Royer: New observations on the thermoluminescence of certain crystallophyllian rocks.

René Bernard: The electronic origin of the nitrogen bands in the spectrum of the aurora borealis. Determination of the energy of the exciting electrons.

J. Cluzet and P. Ponthus: The variations of the electrical conductivity of the air as a function of the barometric pressure, in the pneumatic caisson.

Mme. Cécile Sosa-Bourdouil: The comparative elementary composition of some floral organs.

René Moricard and Pierre de Fonbrune: A new technique for the study *in vitro* of the maturation mitoses of the ovum in mammals. The case of parthenogenetic segmentation.

Raoul Lecoq: Do the fatty acids of high melting point (above 50° C.) upset the food equilibrium in the same way as the fatty acids liquid at the temperature of the organism?

René Herpin: The role of sea-acorns and of serpulæ in the fouling of ships' hulls.

Mme. Paulette Chaix: The oxidation and fermentation of glucose by *Propionibacterium pentosaceum*.

Claude Fromageot and Georges Bost: The reducing power of living yeasts in the course of alcoholic fermentation.

Henri Colin and Henri Belval: Cane sugar gum.

Michel Weinberg and Mlle. Maylis Guillaumie: The titration of antitoxic sera.

D. Broun: The modifications brought about in the action of insulin by the addition of a colloidal suspension (gelatin).

Moscow

Academy of Sciences (*C.R.*, 14, No. 1, 1937).

M. Krein: Some problems of the geometry of convexities situated in a complete linear space.

D. Raikov: Decomposition of Poisson laws.

V. I. Smirnov: Solution of a problem of limits for the equation of curves in the case of the circle and the sphere.

W. A. Ishnailski and B. M. Bogoslowski: Colour of the nitrobenzol derivatives of aromatic amines (4). Auxo-enoid system separated from chromophore.

F. M. Šemiakin: A new kind of multiple emulsion and on spontaneous formation of emulsion systems.

A. A. Jacenko-Chmelevskij: Transformation of the plastic matter in wood after the cutting of a tree.

S. A. Borovik and A. F. Susedko: Presence of gallium in the samples collected by expeditions of the Lomonsoff Institute of the Academy of Sciences of the U.S.S.R. Greater quantities of gallium are found in minerals of endogenous origin than in those of exogenous origin, and muscovite contains up to 0·1 per cent of gallium.

A. M. Arenstein: Evaporation from water reservoirs overgrown with aquatic plants.

V. Kirpičnikov: Principal genes of scales in carp.

N. N. Medvedev: Body-colour mutants in *Drosophila* as studied by transplantation.

V. P. Popov: The role of combined water in the frost resistance of winter wheat.

D. Tretiakov: Spectacles in the anchovy (*Engraulis encrassicolus*).

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Saturday, May 1

Royal Institution, at 5.—Annual Meeting.

Monday, May 3

University College, London, at 5.—Prof. H. Rein: "Some Economising Mechanisms as a Condition of the Body's Adaptation to Increased Activity" (succeeding lectures on May 4 and 6).*

Imperial College of Science and Technology (Huxley Building) at 5.30.—Prof. H. H. Plaskett: "Problems in Astrophysics" (succeeding lectures on May 10 and 13).*

Royal Geographical Society, at 8.30.—Miss Isobel Hutchison: "Plant-hunting in the Aleutian and Pribilof Islands".

Tuesday, May 4

Royal Institution, at 2.30.—Prof. K. S. Krishnan: "Some Aspects of Crystal Physics" (succeeding lectures on May 5 and 6).*

Imperial College of Science and Technology, at 5.30.—Sir Thomas Holland, F.R.S.: "The Permanence of Oceanic Depressions and Continental Elevations" (Huxley Memorial Lecture).

Wednesday, May 5

Institute of Metals, at 8—(at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1).—Prof. E. N. da C. Andrade, F.R.S.: "The Flow of Metals".

Royal Society of Arts, at 8.15.—Prof. A. W. Nash: "The Fuel Supplies of Great Britain".

Thursday, May 6

Institution of Electrical Engineers, at 6.—Annual General Meeting.

R. S. Whipple: "Electricity in the Hospital (Faraday Lecture).

Friday, May 7

Institution of Electrical Engineers (Meter and Instrument Section), at 7.—Sir Frank Smith, F.R.S.: "Fundamental Electrical Measurements".

Geologists' Association, at 7.30—(at University College, London, W.C.1).—N. E. Odell: "Nanda Devi, Central Himalaya".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned

Two Women Assistants at the Low Temperature Research Station, Downing Street, Cambridge, to prepare index of literature of food investigation—The Superintendent (May 3).

Assistant (grade II, ref 429 *O*), Two Assistants (grade II, ref. 426 *O*), Assistant (grade II, ref 428 *O*), Assistant (ref. 431 *O*), and Assistants (grade III, refs. 432 *O* and 433 *O*) at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (May 7).

Lecturer in Mechanical Engineering in the County Technical College, Worksop—The Principal (May 8).

Inspectors of Agricultural and Horticultural Education and Research for the Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1—The Secretary (May 10)

Head of the Lancaster Storey Institute Technical College and Junior Technical School—The Director of Education, Education Department, High Street House, Lancaster (May 10).

Superintendent of Commercial Horticulture for the Middlesex County Council—The Clerk of the County Council, Guildhall, Westminster, S W.1 (May 11).

University Professor of Bacteriology in University College Hospital Medical School—The Academic Registrar, University of London, W C 1 (May 14)

Lecturer in Civil Engineering in the University of Bristol—The Registrar (May 17).

A Physicist and a Biologist at the Bermuda Biological Station—The Secretary, Bermuda Oceanographical Committee, The Royal Society, Burlington House, W.1 (May 20).

University Professor of Physical Chemistry in Birkbeck College—The Academic Registrar, University of London, W.C.1 (May 21).

Woman Lecturer in Geography and Physics in the Huguenot University College, Wellington—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (May 25)

Meteorologist for the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S W.1 (May 31).

Chemists in the War Department—The Under-Secretary of State (C.5), War Office, S W.1 (quote Appts. 30)

Assistant in Engineering in the County Technical College, Dartford—F. L. Notley, 11 Essex Road, Dartford

Two Assistant Lecturers in Mathematics in the Royal Holloway College, Englefield Green, Surrey—The Principal

Lecturer in Engineering in University College, Rangoon—The Secretary, Universities Bureau of the British Empire, 88A, Gower Street, W.C 1.

Headmaster of the Worsley Junior Technical School and Technical Institute—The Secretary, Worsley Higher Education Committee, Town Hall, Walkden, near Manchester.

The Ceremonial of Coronation

IN the ceremonial and pageantry of coronation, such as that now at hand, there draws to a close a period of transition in which the royal power passes from dead to living. The solemn investiture of the new monarch with the symbols of kingly dignity and the acclamation and rejoicings of his people mark the final stage in a ritual of change, which, from the earliest days of primitive kingship, has been held of gravest moment for the community. Although we may no longer believe with our primitive forefathers, as still do some of the less-advanced peoples of to-day, that the vigour and fertility of crops and herds, and even the prosperity of the nation, may depend directly upon the virility of the ruler, this much of the mystical lingers in our mode of thought, that only with the ceremonial of coronation do we feel that we have passed in full sense from waters, which might prove turbulent, to the haven of a new reign.

To the coronation of His Majesty King George VI, must be attached an added significance over that of his predecessors. The change in the interrelation of the constituent parts of the Empire under the provisions of the Statute of Westminster has thrown into high relief the personal responsibility which now rests upon the King-Emperor as the sole constitutional link of Empire. For the first time the Coronation Oath, in its amended form, assumes a position of outstanding import in the ceremonial observances. It has become something more than the solemn undertaking to make just use of the royal prerogative than it has been in the past. In the imperial sense, it is now the head and front of the rite.

This process of evolutionary development, which we see taking place before our eyes, is in full accord with the history of the ceremonial of coronation in Great Britain. Like the British constitution, of which it is an appanage, its ability to endure rests on its capacity to change without break in continuity. So far from being a collection of survivals, the coronation ceremonial, even though close parallels may be cited from ancient pagan custom and the practices of 'savages', in each of its rites expresses some one aspect or another of the emotional force which inspires workaday citizenship. Each change in form, and more especially each variation in emphasis as between the elements in the ceremonial, to be marked in the course of its history, has expressed the general sense of the community at that period in its reactions of loyalty towards the monarch, successively as head of the English State, as ruler of the United Kingdom, and as King-Emperor of the Empire.

The British ceremonial of coronation, like the monarchy, is the oldest in the European States which still adhere to the monarchical form of government. It is also the most elaborate. Its history begins in the eighth century with an Anglo-Saxon rite, in which the ceremony of sacring the king was introduced in the middle of a Mass. Oil was poured from a horn on the king's head, the anthem "Zadok the Priest" was sung, the bishops and nobles placed a sceptre in the king's hand, the staff was delivered to him, and finally a helmet was placed upon his head. The assembly then cried "May King . . . live for ever". The enthronement followed, and the nobles swore fealty. The Mass then concluded with special prayers.

In part, and especially in so far as it was an enthronement with acclamation, this ceremony was of much earlier origin. The Germanic tribes, after the election of their ruling chief, used to enthrone or elevate him on their shields. He was then carried on the shields around the assembled people on the shoulders of certain of the nobles. This custom was adopted by the Franks, and was the method by which Clovis and his immediate successors were elevated to the throne. It continued in use for some time after the introduction of Christianity with the addition of a religious service. It survived in part in the procession from the Tower to Westminster and the elevation to the marble throne in the English ceremony, and in France in the showing of the king to the people.

The tribal ceremonial, in which the elected chief was elevated on the shields of his subjects, in accordance with the needs of the times, symbolized his function as leader of his people, more especially in war. With the coming of Christianity and the participation of the Church in affairs of State, another aspect of kingship, no less primitive, was brought into prominence in the inaugural ceremony. This was the spiritual and magico-religious element, which in early and primitive forms of the kingship identifies the ruler with divinity or accredits him with magical powers to be used for the benefit of his people. In the coronation ceremonial of Western Europe, its immediate source must be sought in the Bible, and as time went on in the Eastern conceptions of monarchy which came with Byzantine influence, rather than directly in survivals of pagan ideas. For although pagan chiefs and rulers claimed descent from heathen deities and demi-gods, such as Odin or Wotan, neither English monarchs nor His Most Christian Majesty of France appear to have laid claim to divinity, but rather to rule through divine influence—by the grace of God. At the same time, a detailed comparison with non-Christian rites indicates so many similarities in form and idea as to suggest at least a strong colouring of a mode of thought, which belongs to a more primitive phase of religious belief. As is well known, the early Church was not averse from adapting the concepts and ideas of paganism to further the advancement of Christianity.

It is a reasonable assumption that the magico-religious conceptions, which Sir James Frazer has shown to play a predominant part in the evolution of early forms of kingship, should be much in evidence at the inauguration of a new ruler. The problem before the primitive mind must always have been how best to ensure that the qualities and powers, which secured in the ruler who has now passed away the prosperity of his people, should be continued in the person of his successor. When the succession was determined by mortal combat, in which the victor either remained, or became, the ruler, as in the priesthood of Nemi, the result determined the issue. Where the cult of the ancestors prevailed, especially when the spirit of an ancestor was believed to reappear on earth in his descendants, as among certain of the Bantu-speaking peoples, the principle of inheritance was adequate to their need. Failing the direct assurance of such determinants, however, it was deemed necessary, as we can see from the character of the inaugural rites themselves, to ensure the continuance of the qualities and powers of the old ruler in the new by a ceremonial which in its origin and essence was magical, or at best magico-religious, however it may have come to be regarded later, when incorporated in a more advanced system of religious belief.

In royal and chiefly inaugural ceremonies which are of a traditional character and not modern innovations, there are certain recurring features, some appearing sporadically, others again and again with regularity. Mr. A. M. Hocart in his acute and ably argued study of the kingship (Oxford, 1927), analysing this ceremonial, notes some twenty-six characteristic features. His analysis is too long to quote here ; but the most important point he makes is that the ceremonial is one in which the ruler dies, and is born again as a god. Among other characters may be mentioned a ritual combat in which the ruler must prove victorious, baptism with water and anointing with oil, investiture with special garments and regalia, the enthronement, the acclamation of the people, the sacrifice of a victim—often human—and usually the bestowing of a new name on the king.

Lest it seem that the interpretation of the coronation ceremonial as a re-birth is somewhat remote from the form of rite with which most are familiar, it may not be out of place to refer briefly to one or two examples which support this contention. Only the more significant points are mentioned.

In the ceremony of inauguration of a ruling chief in Fiji, which Mr. Hocart quotes as his 'type specimen', a specially prepared sheet of barkcloth is wrapped round the chief's arm, and a bowl of kava is presented to him, after a period of fasting and abstinence. When he drank this, he was not permitted to take the bowl with the arm which had been swathed in the bark-cloth sash. For four nights kava was made; and at the end of that period the chief bathed, while a raid on a village secured a human victim who was killed, baked and eaten at a feast. At one point in the proceedings a man offered to fight as a champion for the chief. Muskets were fired so that the whole land might know that the ceremony was completed.

The points of interest in connexion with this ceremonial are that in part it is similar to the ritual which is observed on the death of a chief, while the ceremonial drinking of kava, and the bark-cloth scarf, apparently are intended to suggest that the god is brought to the chief in the bark-cloth and enters his body after he has died in the form of the kava. He is then born again and bathes to cleanse himself from the impurities of the womb.

The theory that the inauguration of a chief or king is a new birth is more clearly brought out in the ancient Indian ritual, in which the priest in investing the king with three garments speaks of two of them as cauls out of which he is born, while the mantle which is thrown over him last of all, is called "the womb of sovereignty". In this ceremony there is a magical victory in a mock fight, while the climax of the rite is a lustration of the enthroned king with a double stream of water. This purification by water is followed by an anointing with clarified butter.

Although little is known of the actual coronation rites of Ancient Egypt, the Sed festival, which took place at a late date in a reign, renewed the vigour of the monarch by a rebirth and rejuvenation in which the rites were in all probability a repetition of the rites of coronation.

The idea of continuity through rebirth is most clearly expressed, perhaps, in the ceremonies which accompany the accession of the Adah of Idah, northern Nigeria—a vigil of eight days at the royal necropolis; a period spent at the "birthplace", where the future ruler is joined by the chief wife of his predecessor; and the action of two officials who sport as man and wife, the latter then mimicking childbirth and delivering the Adah to the chief eunuch as 'her' son. The Adah is then divested of his birth garments and adorned with the royal robes.

While it is undoubtedly true that neither in France nor in England, as already mentioned, was it claimed that the king was divine, yet there are many similarities in detail with the ceremonies mentioned which are suggestive of at least a cognate mode of thought, and it may be even a more intimate connexion: the vigil—no longer observed—the anointing, the robing and investiture, the acclamation of the people, the perambulation, and the challenge of the king's champion, which takes the place of the ritual combat, though the office and not the rite alone remains.

Most significant, perhaps, in the older ritual is the ceremony of the anointing, which until the Reformation was the most important element in the ceremonial. By it, the person of the king was made sacred. Indeed it was held by some that the king henceforth was both priest and layman; and although this doctrine does not seem to have prevailed in England, in France the king appears to have held priestly office and on occasion is said to have officiated in priestly vestments. It is evident that in both the English and the French ceremonial the Divine Spirit and the kingly office were brought into peculiarly intimate relation. These two closely related forms of the rite, with the Empire, made use of the chrism, the most sacred of the blessed oils, in France mixed with a drop of oil from *La Saincte Ampoule*, in which the Holy Dove had once placed holy oil for the coronation of Clovis, in England from the time of Edward II, when the coronation ritual reached its most elaborate development, for anointing the parts of the king's body, while for his head was used oil from the flask which, as the Pope wrote to Edward, the Virgin Mary had delivered to Thomas à Becket for that use at some later day. From this anointing the two monarchs derived their power of healing by 'touching' for the King's Evil.

With the Reformation and the personal rule of the Tudors, the idea of the sanctification of the king's person gave place to other concepts of monarchy. The importance of the unction waned to give place to the ceremonial of placing on the monarch's head the crown, the symbol of territorial dominion, as had been shown by the triple crown of Charlemagne, silver for Germany, gold for Rome, and the sacred crown of iron, made from a nail of the Cross, for Lombardy. The crown, it is true, is not without a 'magic' of its own—otherwise why should our kings still be crowned with the crown of St. Edward, though that venerable relic was broken up under the Commonwealth—but its real significance lies not in its interpretation as a survival, but in its living meaning as an emblem of a constitutional and personal relation between king and people.

Audubon the Magnificent

(1) Audubon

By Constance Rourke. Pp. vii+342+12 plates. (London, Bombay and Sydney: George G. Harrap and Co. Ltd., 1936.) 12*s*. 6*d*. net.

(2) Singing in the Wilderness:

a Salute to John James Audubon. By Donald Culross Peattie. (Country Books, 2.) Pp. xvi+245+8 plates. (London: George Allen and Unwin, Ltd., 1936.) 7*s*. 6*d*. net.

(1) THIS is the biography of a genius in ornithological art, in the early days of American science and culture. But more than this, it is the story of a personality so gallant and vivid, so unworldly and unbusinesslike, so unconquerably gay in adversity and prosperity alike, as to make extraordinary the present-day ignorance of him and his work. He was the pioneer of a new ornithology, describing birds as living and sentient beings rather than as specimens—more naturalist than man of science, and perhaps more artist than either.

Mystery surrounds his birth. He was adopted at the age of nine years by Captain and Mrs. Audubon. Captain Audubon, son of a poor fisherman, owned a merchant ship which traded in San Domingo, where he bought a sugar plantation and prospered greatly. During his stay on the island, a boy was born to a Mdlle. Rabin, for whom Captain Audubon evidently felt some responsibility. He therefore took a boy with him when he left San Domingo for his home in Nantes and he and his lawful wife formally adopted a boy four years later, of an age to correspond with the birth of Mdlle. Rabin's son. The Audubons later used the name of Jean Rabin to indicate this boy. In the face of these facts, it must be due to the general glamour of the man, that Miss Rourke indulges in special pleading for identifying the future naturalist with the little son of Louis XVI, the lost Dauphin.

The boy had very strong tastes from the first, seeking the woods and streams at all times, for ever trying to observe, draw, and stuff birds. He was a handsome healthy boy and was intended for the Navy, but Captain Audubon had to remove him from the naval school as he was always playing truant. For a time he studied in Paris under David, the great art teacher, but classical drawing had no charms for him, and he returned home. Eventually Captain Audubon sent him to America, to manage an estate of his, Mill Grove, at that time in the care of Quakers. Here he had great freedom, hunting, drawing, shooting, and making friends with the neighbouring settlers.

An English family named Bakewell lived near Mill Grove, and the young Audubon and Lucy Bakewell fell in love at first sight, and irrevocably. Never was man more fortunate in his love, for Lucy understood his wayward nature, was convinced of his greatness, and bore with cheerfulness the poverty and hardship of his early years.

Young Audubon's business misfortunes began early, and he returned to Nantes for a year. His adopted father arranged a partnership between him and an earnest youth, Ferdinand Rozier, and they were smuggled out to America to avoid conscription in Napoleon's forces. Audubon was henceforward known as John James Audubon. After some time, the young partners began storekeeping, and in this book we have the account of the long journey of the newly wed Audubon and Lucy, by coach and "flat boat" to Louisville on the Ohio, at that time a "frontier village". The account of this journey is a delightful piece of description. Louisville was the centre of a small settlement of French refugees of good birth, and one of these, Nicholas Berthoud, married Lucy's sister later and was a great help to the Audubons. Throughout all this time, Audubon was making drawings ot birds, perfecting his technique, rushing off to the woods and streams in season and out of season. His personality made friends for him, but his lack of any business instinct, and his inveterate habit of playing truant from business, must have been a sore trial to poor Rozier.

Kentucky was a birds' paradise at that time, and Audubon became less and less of a storekeeper and more of an artist-naturalist. At Louisville he had the first of his two meetings with Alexander Wilson, his predecessor in American ornithology Wilson had started life as a poor Scottish weaver, was self-taught, anxious, reserved and dour. He was travelling in order to get commissions for his work "American Ornithology". Audubon showed his own drawings, which Wilson praised, and the two went "hunting" together, but without any resultant friendship. Audubon's poverty and possibly a certain jealousy prevented him from subscribing to Wilson's book, and Wilson records surprisingly that he left Louisville without receiving one act of courtesy, one subscription or seeing one new bird. Audubon gives a different account of the meeting, but the result of it was a rancour and jealousy on Wilson's part which extended to his supporters, publishers and others, and pursued

Audubon throughout his career. Audubon never denied Wilson's priority, but it is certain that the clash of two such different temperaments produced in each a jealous antipathy.

Miss Rourke takes us through the various phases of Audubon's business ventures, interspersed with lively interludes of voyage and hunting, ending with the breaking of the partnership, and Audubon's ultimate bankruptcy. He was now thirty-five years old, penniless; Lucy had helped him by teaching and by her own private fortune. By this time they had two sons, and had buried two little girls. Audubon's record effectually closed the door to other employment in commerce. It was now, when most men would have been in despair, that Audubon, and with him the faithful Lucy, became convinced anew of his genius, and decided that he should publish a great book "The Birds of America". Lucy and the boys remained behind, and the father set off for New Orleans, later to Philadelphia, to seek the wherewithal for publication. Many were his failures and vicissitudes; he taught dancing, he painted portraits, he stuffed specimens for museums. His drawings did not find favour with publishers in America, and moreover he suffered from the active animosity of Wilson's publishers, who wanted no rival "Ornithology". Eventually in 1826 he was able to go to England. He was well received in Liverpool, and in Edinburgh he was elected fellow of its Royal Society. He met Sir Walter Scott, Bewick and other men of note. Lizars, the engraver of Selby's "Book of British Birds", undertook to prepare plates from Audubon's pictures, but later gave up, and Havell, the London engraver, took the work in hand. Audubon's faith in himself was such that he decided to publish in four great volumes, double elephant, although ten years would be needed for completion. He toured England for subscriptions, and also France, meanwhile painting portraits and selling drawings. When he had a little money, he sent gloriously extravagant presents to his Lucy.

Two years passed, and Audubon returned to America to make still more drawings. Subscriptions were coming in slowly, but enough to secure continuance of publication. He returned to England, Lucy with him now, and faced a storm of attacks this time on the truth of his observation. But now at last Audubon's star was in the ascendant; he had many good friends, Sir Thomas Lawrence, Christopher North and others. A new project was started, and the "Ornithological Biography" was begun, as companion text to the great work. For this he had the inestimable help of William McGillivray, who gave scientific value to the publication. Audubon's individual treatment of the book was shown in the interposition of "Episodes" of hunting adventures between the scientific descriptions. Despite warnings, and the growing volume of animosity from Wilson's partisans, he published the first volume himself, and, elated by its enthusiastic reception, returned to America for another joyous hunting excursion. His sons were now able to work with him.

The magnificent "Birds of America" was published in 1839, and, the "Biography" being also finished, Audubon and his family returned to America and settled in Harlem. America, having failed to recognize his worth earlier, now rushed to acclaim him, and the rest of his life was spent in happy pursuit of art, music and natural history. Another work "The Quadrupeds of North America" was carried through, largely with the help of Audubon's sons, and Mr. Bachman. Audubon's sight failed some years before he died in 1851, and at last his mind had dimmed.

Audubon was an artist rather than a scientific ornithologist and as such was a surprise to his generation. His very technique was new—water-colour combined with pastel. New also was the presentation of birds in active movement, and in natural surroundings of flower and leaf. Most surprising of all is the decorative balance of each plate; some of them are instinct with a feeling beyond art or bare naturalistic presentment. Like Audubon's character, his work is something unique and apart, joyous and spontaneous, yet entirely individual and determined.

(2) Mr. Peattie's book is in a measure complementary to the other. It is written almost in 'novel' form, and centres round the love idyll rather than the grim struggles for fame. The earlier part of Audubon's life is more fully treated than are his efforts in England. The illustrations are particularly well chosen. The coloured frontispiece shows Audubon's decorative art at its best, and we note the tender beauty of the pictures "Passenger Pigeons" and "Barn Swallows". The interesting self-portrait of the artist shows the limitations of the amateur in this *métier*, in contrast with his mastery in bird illustration. Those who lack leisure for the longer biography, will find here an unforgettable presentation of a unique and great personality.

Both books before us contain illustrations representative of Audubon's art. Both contain a wealth of anecdote culled from his journals, which he wrote almost all his life. The accounts of his long struggle for means to accomplish his destiny fill the reader with alternate hope and despair, sympathy for his business partners and unbounded respect for his Lucy. The records of his journeys on the rivers are valuable as history of a bygone day, and the beauty conjured up by them is a sad reminder of the glories that commerce and ever-increasing population have destroyed. E. G. G

Primitive Behaviour

Primitive Behavior
an Introduction to the Social Sciences. By William I. Thomas. (McGraw-Hill Publications in Sociology.) Pp. ix + 847. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 30*s*.

THE impulse to collect is almost universal. Some people collect cigarette cards, others stamps or coins. Ethnological museums collect the skulls, weapons, utensils and works of art of primitive societies. Mr. Thomas has collected records of their customs and beliefs. Like most collectors, he has carefully arranged and catalogued his booty. Therefore his eight hundred closely printed pages of facts will be invaluable, as a work of reference, to the student. But those who seek explanations, or the stimulus of theory, will have to go elsewhere. Mr. Thomas has not, indeed, refrained from comment altogether. He has adopted certain general conclusions. He believes that different peoples have reacted in different ways to similar situations, and so rejects the over-simplified view that development has been unilinear. He believes that a society is more influenced by its neighbours than by its physical surroundings—that the cultural area is more important than the geographical area; and he believes that any innate differences there may be between different races has had little or no effect on their respective cultures. Here Mr. Thomas, in repudiating an over-emphasis on innate factors, seems to have gone to the opposite extreme.

Apart from these general conclusions, there are few theories to be welcomed or attacked. Mr. Thomas, therefore, has had no temptation to select his material, and has collected it entirely without bias. But the striking feature of the book is not that explanations are avoided—this might be the result of caution—but that Mr. Thomas finds so little to explain. The astonishing persistence of a primitive custom, even when it serves no obvious function, is, for him, only a particular example of the perseveration of habit. Thus the real problems of psychology do not exist for him at all. Had he paid more regard to the fact that the perseveration of habits varies within wide limits, that while some are unbreakable others can be broken without effort, his curiosity would have been less easily satisfied, and he would have suspected the presence of hidden motives behind those primitive customs which are unalterably fixed. Had he suspected the presence of hidden motives for the persistence of a custom, he would have suspected that the same motives might have been, in part, responsible also for its origin.

To take an example: Mr. Thomas sees in the Jewish abhorrence for the flesh of pigs a habit, which through long duration has acquired the force of law. He does not feel the need for any further explanation. As, for him, no special motive is required to account for the perpetuation of this taboo, he is prepared to believe it originated without a motive—at any rate, he quotes, with evident approval, an author who derives this 'habit' from the supposed difficulties of pig-keeping in an arid land. Or, take another taboo, that of incest and the marriage of near kinsmen. Here Mr. Thomas finds a real motive: the desire to establish an alliance between two groups, or to have relations-in-law on whom to call in case of need. This is sound enough, so far as it goes. But such a practical consideration can scarcely account for the extreme horror of incest, for the common belief that it blights the crops and brings nameless calamities not only on the guilty couple, but also upon their clan. This extreme horror is, for Mr. Thomas, merely another example of the rigidity with which any long-standing habit comes to be observed. But the curiosity of anyone who is not hypnotized by that magic word 'conditioned reflex' will not be lulled so easily to sleep.

The obsessional neurotic has certain taboos and rituals of his own. For example, he cannot touch a knife, or must dress in a particular order. If he touches a knife accidentally, he is overwhelmed with nameless dread. If he makes an error in the order of his dressing, for example, cleans his teeth before he brushes his hair, he must go back to bed and begin all over again. If he is prevented from doing so, he suffers an outbreak of acute anxiety—as acute as if his wife or children were dangerously ill; indeed, he often feels dimly that they are in some mysterious way threatened by his lapse. Are such obsessional taboos and rituals trains of conditioned reflexes, mere habit systems? Certainly, but so is a great part of normal behaviour, which, nevertheless, can be broken without anxiety. There is clearly some important factor that distinguishes the obsessional from the non-obsessional habit, which is ignored when the same word is used, without qualification, for both.

Now many of the taboos and rituals of primitive people are obviously obsessional—as Freud pointed out in 1912. Primitive man, indeed, is an obsessional neurotic, who is provided by tradition with taboos and rituals, and thus saved the trouble of developing private symptoms of his own. Freud's explanation of these taboos and rituals may be neither wholly accurate nor complete. In particular, the secondary social advantage, where it exists, is important and should not be neglected. But to ignore the deeper motives, to dismiss primitive behaviour as habit fixed by repetition, originating in a judgment—wrong perhaps, but reasonable within the limits of primitive man's intelligence and knowledge—this is to make a retrogressive step, which can only lead to the complete sterility of socio-psychological research.

Although Mr. Thomas is blind to the deeper motives behind primitive behaviour, he has a good eye for secondary and social motives; and as a collector and classifier he can have few rivals. His book is a mine of information, and may retain its value far longer than would a more stimulating and imaginative work, which would almost inevitably have soon been obsolete.

ROGER MONEY-KYRLE.

A Yearbook of British Universities

The Yearbook of the Universities of the Empire, 1937

(Published for the Universities Bureau of the British Empire.) Pp. xxix+1125. (London: G. Bell and Sons, Ltd., 1937.) 15*s*. net.

THE present issue of this handy guide to the learned world follows closely the lines of its recent predecessors. The main body of the work consists of a series of summary accounts, one for each university, grouped by countries and each comprising: (1) a directory of the officers and members of the staff of the university, (2) general information regarding organization, etc., and (3) reports of events of outstanding interest which occurred during the past year. Preceding the compendia relating to the institutions in (1) Great Britain and Ireland, (2) Canada, (3) Australia, (4) South Africa and (5) India, respectively, are five chapters reviewing their history, regulations, practice and distinguishing characteristics. Appendixes deal with: professions and careers, admission to universities, open post-graduate scholarships, etc. (several hundred paragraphs covering 47 pages), centres of scientific research and information (70 pages), and other matters of interest to the learned world and the public generally.

Of the Universities Bureau of the British Empire, the body responsible for the production of the Yearbook, full particulars (memorandum and articles of association and membership) are given on pages x–xxix. Among the objects are "to facilitate . . . the interchange of information . . . and . . . of students and teachers between the said universities and between them and the universities of foreign countries". It is therefore natural that in the reports of events of the past year, a considerable amount of space should be devoted to particulars of "visits of teachers from other universities, etc.". It is noteworthy, at a time when channels of international intercourse are deliberately obstructed in pursuit of nationalistic policies, that many visitors from foreign countries lecture in the universities of Great Britain. The list of visitors to Cambridge, for example, includes professors from Harvard, Paris, Breslau, Copenhagen, Amsterdam, Utrecht, Lund, Lwow, Madrid. The significance of such international visits would perhaps be more strikingly disclosed if the particulars of them were exhibited in one place instead of being scattered among the several university sections.

As regards students from other countries in the universities and university colleges of Great Britain and Ireland, a numerical statement compiled from returns received from all those institutions (except Trinity College, Oxford), appears on pp. 994–995. It gives the total number of such students as 5,882, which is one tenth of the total number of *full-time* students in those institutions. It reveals the remarkable fact that German students (416) outnumbered those from any other European country by more than five to one. Switzerland came next with 77, then France (76), Poland (72), Holland (69), Norway (50), Austria (44), Hungary (38). Other notable contributions were from India (1313), China (295), Palestine (157), Egypt (348), South Africa (568), United States (592), Canada and Newfoundland (280), Australia (248), New Zealand (148).

In fulfilment of one of its principal objects, the Universities Bureau organized last year the fifth quinquennial Congress of Universities of the Empire, which was held at Cambridge last July. It seems odd that the Yearbook should contain no reference to this event except by the inclusion of the Congress report in a list of books on p. 1015. In a "Yearbook of the Universities", should not some record of such outstanding events of the year, directly affecting them though not peculiar to any one of them, find a place in a general or regional chapter ?

Lecture Experiments in Chemistry

By G. Fowles. Pp. xvi + 564. (London: G. Bell and Sons, Ltd., 1937.) 16*s.* net.

One of the difficulties facing the young teacher of chemistry is the devising and executing of experiments suitable for class and laboratory use. For some years before taking up the first post, the teacher will have been performing experiments in what are regarded as more advanced parts of the subject, and when the time comes to deal with the supposedly simple experiments involved in a course of School Certificate standard, trouble begins for those who are unaware of the great difficulty of many such experiments and have not the necessary skill and experience.

To such teachers the work of Mr. Fowles will be both welcome and beneficial. His book is confined mostly to School Certificate standard, and the material is arranged in lessons, which will also be useful until the teacher has enough confidence to evolve an independent scheme of teaching. Many alternative experiments are given, and the references to books will be useful to older teachers who wish to keep up to date. Several sections deal with subjects not adequately dealt with in the usual text-books, such as colloids, indicators, etc., although in some cases the treatment here seems rather too difficult for the standard at which Mr. Fowles aims.

There is some repetition in the book, as for example, when the preparation of a gas such as ammonia is described several times in different experiments, and the size of the book could have been materially reduced by more careful arrangement of material, cross references, etc. The appendixes on aims and methods of teaching chemistry will be read with interest by teachers. The range of the book is too restricted to make it of much use in more advanced courses, and the disconnected order is also a drawback to its use in courses in universities, for which it is obviously not intended.

The Extra Pharmacopoeia

By W. Martindale. Twenty-first edition. In 2 vols. Vol. 1. Pp. xxxv + 1182. (London: The Pharmaceutical Press, 1936.) 27*s.* 6*d.*

The Pharmaceutical Press has now taken over the publication of this standard work from Messrs. H. K. Lewis and Co., Ltd. A new edition of the first volume has now appeared with an enlarged page and a blue cover. This volume is complete in itself and gives an account of the pharmaceutical and therapeutic properties of practically all the drugs prescribed by medical men. The revision must have involved a great deal of work, even when divided among seventeen pharmacists. Thousands of references to recent medical literature have been included, in the place of older and less important information.

The general arrangement has been to some extent rationalized, so that drugs with similar actions appear together, but the process has not been carried far enough. For example, the section on acidum aceticum in the twentieth edition included the acetates, acetylcholine, choline, glycine and betaine hydrochloride. The latter has been properly transferred to the section on hydrochloric acid, but choline has been left where it was, with new company in the form of thallium acetate and cysteine. The extensive index largely compensates for defects of arrangement, but it would be difficult, for example, to find the substance commonly known as benzedrine under the alias of desoxynorephedrine.

The book contains an amazing quantity of information and is remarkably up to date. The inclusion of the names of manufacturers of proprietary remedies is a very welcome addition. The information about these substances will do much to encourage rational prescribing. Every medical man and every pharmacist should possess this book.

A Monograph of the British Neuroptera

By F. J. Killington. Vol. 1. (Ray Society Vol. 122 for the Year 1935.) Pp. xix + 269 + 15 plates. (London: Bernard Quaritch, Ltd., 1936.) 25*s.*

It is now nearly seventy years since the appearance of McLachlan's monograph on British Neuroptera. In the meantime, the most notable contributions to a knowledge of this subject have been the studies by the late C. L. Withycombe, which were mainly in the fields of morphology and biology. The book before us provides, as nearly as possible, a complete account of the British members of the Planipennia. Its author has also incorporated the results of his own observations, and has succeeded in producing a remarkably well-balanced treatise. It is gratifying to see morphology, biology and taxonomy all come in for adequate treatment.

The first 180 pages provide the reader with a general introduction to the order, including also some accounts of its fossil representatives and of the phylogeny. There follows a detailed treatment of the British species up to the beginning of the family Hemerobiidæ. The rest of this family, together with the whole of the Chrysopidæ, are to form the subject of a second volume which has yet to appear. The book is well arranged and excellently illustrated, the greater number of the figures being new. The author is to be congratulated on having produced a work of real merit and of a character which might well be emulated by monographers of other groups.

A. D. I.

Aeroplane Structures

By Dr. A. J. Sutton Pippard and Capt. J. Laurence Pritchard. Second edition. Pp. xvi + 368 + 13 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 21*s.* net.

This book forms an excellent introduction to the problems connected with the structural design of aircraft. The presentation starts from first principles, which are fully explained, and proceeds in easy steps to numerous practical applications, many of which are carried through to the numerical solution. A number of diagrams and tables should prove also of value for those engaged in actual design work. The authors, whose great practical and teaching experience makes itself felt throughout the book, have succeeded in bringing home the fundamentals, and the book can be unreservedly recommended. A. B.

Optical Contact*

By the Right Hon. Lord Rayleigh, F.R.S.

WHEN two glass surfaces are put together without special precautions, they do not come into close contact, and their separate individuality is completely preserved. Yet this is not what might be expected. If the two glasses were really close, they would be equivalent to one piece, and no reflexion would be observable from the interface. Ordinarily this does not happen, because various agencies prevent the glasses coming close enough together. Thus particles of dust and traces of grease tend to do this, and moreover, ordinary surfaces, such as those of spectacle prisms, are not flat enough to come into close contact, except over a very limited area.

However, by using really flat surfaces, scrupulously clean, and by sliding them together so as to exclude dust, two surfaces may be made to *contact*, that is to say, they will come into contact so close that the reflexion at the interface practically vanishes, and when once this has been achieved –and it is easier said than done—the glasses adhere with very considerable force. Such glasses are said to be in optical contact.

Although, as we shall see, the germs of this subject are to be discovered in much earlier work, optical contact has mainly come into notice in connection with the manufactures of Messrs. Adam Hilger, Ltd., under the management of Mr. F. Twyman; Mr. Green, the foreman of their optical shop, has been prominent in this. To mention one example, the echelon transmission gratings made by the firm have the glass plates put into optical contact, which improves the transparency and makes the instrument much more efficient. I have heard the late Prof. A. A. Michelson, who was perhaps not very lavish of praise, speak with enthusiasm of this great improvement in his invention. Nevertheless, the interface, even of contacted glass, does give a faint reflexion. I shall have more to say about this presently.

There is a strong force of adhesion between two contacted glasses. Glasses having an area of less than 2 square inches can be shown to withstand a pull of 56 lb. weight. On occasion, contacted glasses have been made to stand even considerably stronger pulls than this, up to 56 kilograms per square centimetre. However, there does not seem to be anything very definite about it, and there is little doubt that the separation starts at points of local weakness.

The germ of this subject can be discovered in the writings of long ago. Let me recall the well-known experiment of Newton's rings. Two glass wedges, one of which has a convex face of 50 ft. radius, are clamped together without any special precautions, except ordinary cleaning, and give by reflection a circular patch of optical contact—the familiar black centre, surrounded by a system of coloured rings. It is interesting to recall that the blackness of the centre was felt to be a difficulty by the early exponents of the wave theory of light. Yet a simple consideration shows that it ought to be black, the consideration namely that an infinitely thin crack is equivalent to no crack at all, and therefore cannot reflect light.

We obtain local optical contact at the centre of Newton's rings without the technical difficulties which are encountered in contacting flat plates. This is natural, because all the pressure that we use is taken locally, and if there is any dirt or obstruction in the way it is crushed.

It may seem a discrepancy in what I have been saying, that the optical contact which we get in this case is not accompanied by strong mechanical adhesion. This fact will conveniently serve as a starting point in considering the character of the adhesion between flat plates. Although the adhesion is very strong in resisting a fair pull, it is not at all strong in resisting what I may call an *unfair* pull, that is to say, a force tending to strip the plates apart. Such a force can be applied by wedging or pulling the plates apart at one edge or one corner, and we then overcome the adhesion in detail, for the force applied is all concentrated at the edge of the contacted area. It is like tearing a strip of calico when a start has been made by making a short cut with the scissors. All the force is concentrated locally, the breadth of the strip of calico contributing nothing to increase its strength. In the case of Newton's rings, when the convex surface is squeezed flat locally, as soon as the force is relaxed the elasticity of the material brings a stripping force of the kind to bear, and the two glasses separate themselves easily.

If, however, the convexity is very slight, and the amount of flattening involved in contact is consequently small, we may obtain Newton's rings with adhesive contact, no clamping being necessary to keep the glasses together (Fig. 1). This case may be regarded as intermediate between the case of Newton's rings and the case of accurately contacted flat plates.

---

* From the Friday evening discourse at the Royal Institution delivered on December 18, 1936.

Newton's rings result when we have contact in the middle, and separation outside; but the converse case may also occur. If a piece of glass gets scratched, experience shows that it becomes difficult to contact it. The reason of this is that the hard particle that causes the scratch, ploughs up a sort of ridge, which of course prevents contact near it. If the scratch is short, we may nevertheless obtain contact at a distance from it by the flexure of the glass. A specimen of this kind shows the scratch in the middle, the interferential tints all around, with contact and blackness at the circumference. If it is allowable to be a little Irish, we might describe it as "Newton's rings with the black centre at the outside." The interferential tints enable us to determine the height of the ridge.

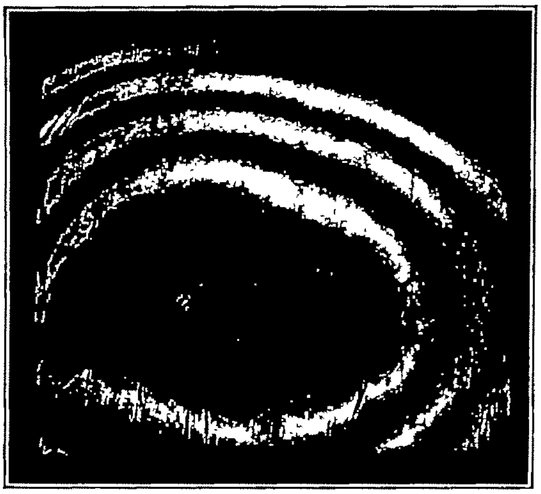

Fig. 1.

Although to a first approximation the reflexion from the interface of contacted plates is black, or in other words non-existent, yet there is a slight reflexion. In the ideal case when the surfaces are in contact the reflexion should be evanescent, but the intensity should increase as they are separated, all this occurring within the range when the interface reflexion is still black to the casual observer. The wave theory allows us to connect the intensity of reflexion with the distance, and it was hoped in this way to obtain a direct measure of the distance between the surfaces, which might be brought into relation with the energy required to separate them.

I found, however, that there was a very curious uncertainty in the amount of reflexion, particularly when surfaces of silica glass were used. I mean that one pair of contacted surfaces would give quite a different reflecting power from another, sometimes ten times as much. What could be the explanation? It was natural to seek it in the character of the surfaces themselves. Since it is not so easy to modify the surfaces experimentally while preserving the flatness necessary for contacting, I thought of trying a single surface immersed in liquid of the same refractive index, which automatically adjusts itself to the shape of the immersed surface. This at once gave a clue to the mystery. Carbon tetrachloride has nearly the same index as fused silica, and by adding a little ether an exact adjustment can be made for green, the brightest part of the spectrum, so that green light passing through a prism of silica immersed in the liquid suffers no deviation.

In this way we get a liquid which matches optically the inside of the silica prism, irrespective of what the optical quality of the skin may be. The skin, on the other hand, determines the reflecting power of the immersed silica. If the skin is the same as the inside, then there should be no reflexion. When I tested a surface commercially polished, there was usually very little reflexion, and if a fired surface, or a surface slightly washed with dilute hydrofluoric acid was used, the reflexion became practically evanescent. On the other hand, any attempt to polish it further with the somewhat amateurish technique of my laboratory increased the reflexion largely; and rubbing it on a dry felt wheel with a very fine abrasive powder did so still more, until a practical maximum had been reached. An abrasive powder used in this way does not destroy the polish. The increase of reflexion produced is so great that it can readily be seen even without immersion.

The felt wheel with the fine abrasive produces a modified skin; and it is interesting to inquire what is the optical character of the skin and, also, what is its thickness? By putting the surface in a series of refracting liquids, we can find which liquid reduces the reflexion to a minimum. I find that a mixture of 75 volumes of carbon disulphide and 25 volumes of benzene, index 1·596, does this. It is to be concluded that the skin is quite as refractive as light flint glass, whereas the body of the silica (index 1·46) is much less refractive than crown glass.

This is a surprising result, and shows that the skin produced by the treatment is something quite different from any of the known modifications of silica. Yet it is difficult to see what else than silica can enter into its composition. By dipping part of the plate in dilute hydrofluoric acid we may dissolve off the modified layer from that part, leaving a kind of step. To estimate the height of this step, we apply a flat test plate and observe the dislocation of interference fringes when they cross the step. In this way the height of the step, and hence the thickness of the layer, has been estimated at $\frac{1}{20}$th of the wave-length of light in air. Fig. 2 shows a strip of this kind; it has, however, been etched more deeply than is necessary to remove the layer. Similar effects to those with silica can be obtained with glass surfaces, but the layer produced by the felt wheel with abrasive is definitely less refractive than in the case of silica, and since the material is more refractive to begin with, the change is a good deal less conspicuous.

Fig. 2.

Returning to the contacted surfaces, it will now not be difficult to understand why some have a stronger reflexion from the interface than others. It is because the ordinary process of polishing is somewhat haphazard. It may produce a modified layer, as the felt wheel with fine abrasive does, or it may remove the layer already produced. This depends on the exact conditions of the polisher. I have verified this, using a cloth polishing wheel with rouge, which was quite wet to begin with and was allowed to dry. The reflexion of the silica surface was tested at intervals, and was found to pass through a minimum at a certain degree of moisture of the polisher. Concurrent weighings showed that this was the stage at which material was being most rapidly removed.

It is evident that if the contacted surfaces are not exactly alike, residual reflexion is to be expected, even if there is no separation of the surfaces. Further, even if they are alike, there will be reflexion at the separating surface between the skin and the body of the material in each of the glasses. If therefore we wish to reduce the interface reflexion to a minimum, we must get rid of the skin. I have tried contacting two glasses which have been deprived of their skin by means of hydrofluoric acid or caustic potash, but this is not as satisfactory as might have been hoped, because the chemical treatment develops all kinds of defects which were latent in the polished surface, and the light scattered by these makes it very difficult to investigate the faint residual reflexion. I have not been able to determine with certainty that the reflexion is in any case less than would correspond to about 10 A. distance between the planes. This is three or four times as much as the distance apart of the atoms in crystals.

In conclusion, I wish to explain how we may determine the amount of work done in separating two contacted surfaces, or even the amount of work which can be gained by the action of the attractive forces when they are contacted. These amounts of work are not the same, for the process of decontacting and contacting again is not, in the thermodynamic sense, reversible. We must start with a contacted surface and slowly tear the contact away. A square of glass is contacted diagonally on to a larger piece, but one corner of the square overlaps the edge (Fig. 3). For security, the two pieces are clamped together as shown by the dotted outline, and the non-contacted surface of the smaller glass is blackened to diminish false light. Projecting the reflexion through the larger basal glass, initially, all is dark. On pulling the corner of the smaller glass away from the larger one with the forefinger, the contact is stripped away, and interference fringes spring into view (Fig. 3*b*). These extend as the pull is increased, five or six orders of colours being brilliantly developed. On releasing the corner, the glass becomes flat again, the contact is restored, the fringe system recedes, and a moment later it vanishes entirely, leaving all dark as at first.

The quantitative experiment is on the same principle; but the pulling apart is done by weights gradually added, instead of by the finger. The glasses are horizontal, and to find how far the weights attached to the corner have descended, we count the number of interference fringes. This shows how much the corner, initially in the plane of the larger glass, has been depressed from it. Hence the work of decontacting may readily be calculated. On removing the weights, the plate recontacts, and the work recovered may be determined. The work spent in bending the glass is readily allowed for. Experiments made in this way gave 71·2 ergs per square centimetre for the work of stripping, and for that recovered by recontacting about half this amount.

Fig. 3.

It is interesting to note that the work done in creating a liquid surface (surface tension × length) is of the same order as this.

Modern Aristotelianism

By Dr. Herbert Dingle

And we do hereby make and constitute the said Society by the Name, President, Council, and Fellows of the Royal Society of London, to be a Body corporate, to be continued under the same Name in a perpetual Succession; and that they and their Successors (whose Studies are to be imployed for the promoting of the Knowledge of natural Things and useful Arts by Experiments . . .) shall . . . (First Charter of the Royal Society, 1662.)

It is, in fact, possible to *derive* the laws of dynamics rationally . . . without recourse to experience. (Prof. E. A. Milne, *Proceedings of the Royal Society*, A, 158, 329; 1937.)

IT is not easy to express in a phrase the idea which early in the seventeenth century became the 'experimental philosophy' now called science, but we shall not err seriously if we adopt the statement that the first step in the study of Nature should be sense observation, no general principles being admitted which are not derived by induction therefrom. The 'Aristotelianism' with which this idea waged what is usually regarded as a successful and final battle was, by contrast, the doctrine that Nature is the visible working-out of general principles known to the human mind apart from sense perception.

Both sides thought of Nature as existing externally and objectively. It would conform better with modern physics to speak of science in more subjective terms as the formulation of rational relations between sense observations. This definition has the advantage of providing an automatic safeguard against the Aristotelian fallacy: Nature conceived objectively may have parts inaccessible to observation about which we are tempted to dogmatize; but if our aim is simply to rationalize observations, such inaccessibles cannot distract us.

Nevertheless, the issue between Galileans and Aristotelians is still sharply defined. In the new language, the controversy was concerned not so much with the proper way of doing a thing as with the thing which it was proper to do: Should we deduce particular conclusions from *a priori* general principles or derive general principles from observations? Intellectual activity involves two elements—call them either Nature and the human mind, or experience and reason. To the Aristotelian the human mind had super-sensory knowledge of the principles which Nature obeyed, or alternatively reason could, apart from sense, dictate the course of experience; to Galileo, Nature was independent, and the mind could watch and try to describe in general terms her processes, or alternatively reason could seek to correlate sense observations into a logical system. To the Aristotelian, man was, in a sense, the measure of all things. To Galileo, "Nature nothing careth whether her abstruse reasons and methods of operating be, or be not, exposed to the Capacity of Men".

History shows few examples of loyalty to a trust comparable with that of the succeeding generations of scientific workers. It is no idle boast that until now the thoughts and practices of men of science have been such as Galileo would have approved. Even merely verbal heresies, such as the statement that science is based on faith in an 'Order of Nature' have been few and harmless; we may have said such things, but we have always acted as though Nature might nothing care for what our minds call order. It is not a light matter, then, when we find in our own day a revival of Aristotelianism in the front ranks of science itself.

The phenomenon may be described in broad terms as an idolatry of which 'The Universe' is the god. Precisely what 'The Universe' means is not always easy to discover; its worship is sometimes mono- and sometimes poly-theistic, and no two votaries appear to bow before the same altar. But its various forms have this in common, that they transcend observation and cannot be derived by induction from observation alone. Furthermore, having been created, they dominate experience instead of representing it.

This cosmolatry, as might be expected, came by metaphysics out of mathematics. What is more surprising is that the world of science generally is accepting it with at best a silent protest, kept inarticulate by a lurking fear that what cannot be understood might haply be true. Thus we find among the general public a vague belief that physics is simply the study of the universe, and in the scientific world itself the wholesale publication of spineless rhetoric the irrationality of which is obscured by a smoke-screen of mathematical symbols. It is worth while to see how this has become possible.

The theory of relativity appears to be the innocent cause. It is no secret that when that theory burst upon the world it was very little understood. The new mathematical knowledge and the uprooting of deep-seated prejudices which understanding demanded were thought exorbitant, and the price was not paid. But the theory could not be ignored. It solved a long-standing astronomical problem and successfully predicted a new phenomenon, and these were the hall-marks of true science. Hence relativity had to be accepted. Now it happened that early in its career it was speculatively applied to the universe, and the most widely read introductions to the theory included descriptions of this application. Consequently the bewildered physical world came to imagine a necessary association between relativity and cosmology and, believing where it could not prove, extended to the cosmical speculations the scientific sanction which had been earned only by the underlying system of mechanics.

This was a mistake. The relation of relativity to the universe is in principle precisely the same as that of Newtonian mechanics: both concern the behaviour of any mechanical system whatever, and can therefore tell us nothing about the peculiar character of any particular system. Newtonian mechanics could not state the number of planets in the solar system or the distribution of masses in the universe, but if these things were found by observation, it could tell how the bodies would interact. Relativity mechanics has exactly the same limitation and the same power—a fact which, so completely has the situation been misunderstood, will probably be news to many physicists. How, then, is it applied to the universe? Simply by making assumptions, which by now have become dogmas. It is assumed that the universe is homogeneous. Why? Because the possible alternatives, being infinitely numerous, must be ignored if we are to make our speculations definite. It is assumed that the universe is isotropic for the same reason. It is assumed that the characteristics of the possibly infinitesimal region we have observed are not merely local but also are copied by all that we have not observed. Why? Because that assumption brings the universe within the scope of our mathematical attainments. In this way we reach our grand modern conception of 'The Universe', on which we proceed to build laws of Nature far superior to those paltry inductions from phenomena that Newton ranted about. Our new laws are universal, eternal, established on the rock of divine mathematics, and in the tumult of their coronation no one hears a still, small voice which says, "Nature nothing careth whether her abstruse reasons and methods of operating be, or be not, exposed to the Capacity of Men."

The new Aristotelianism has now grown so confident that we have no need to unmask it: it has itself discarded masks, and we have only to recognize it for what it is. Sir Arthur Eddington, for whom the "cosmical constant", which Prof. A. Einstein thinks illusory, is a "fundamental constant of nature", tells us that "there is nothing in the whole system of laws of physics that cannot be deduced unambiguously from epistemological considerations. An intelligence, unacquainted with our universe, but acquainted with the system of thought by which the human mind interprets to itself the content of its sensory experience, should be able to attain all the knowledge of physics that we have attained by experiment". But Eddington's own practice refutes his creed. He is too great to be the slave of chimæras, and his generalizations are but unsuccessful attempts to utter what he finds inexpressible. If he had a philosophy big enough for his intuitions we should know something.

Prof. E. A. Milne's "kinematical relativity" has quite a different character. Here we not only establish mechanics on 'The Universe' instead of on Newton's "manifest phenomena", but also we invent our own universe so as to be seraphically free from the least taint of observability. This creation is defined by the "Cosmological Principle", which selects out of all conceivable bodies those which, if they had observers on them, would restrict the behaviour of such observers to a certain mutual conformability. Verbal respect is paid to old-fashioned prejudices by the admission that there *is* an actual universe of which this is only a selected part, and, etiquette having thus been observed, hundreds of pages and thousands of pounds are being spent on calculation of the properties of this "selection" by a growing army of "research" workers. In this campaign observations can be what they will provided the functions keep their ancient places; a question is "answered" when the equation is formulated. Thus the question how long the system of nebulæ has existed is "resolved" by saying that it may be for years or it may be for ever, "according to circumstances". The further question, how the possible "circumstances" are related to experience, is not worthy even to be asked. "Whether the actual universe follows the details of the extrapolation is quite immaterial," says Milne. In other words, we admit that Galileo had a programme, but we, for our part, will be Aristotelians.

Perhaps this comparison is unfair, for no one can deny to the Aristotelians the gift of logical acumen. To their modern representatives it seems as though a fancy is no sooner in the head than it is on paper and sent for publication regardless of logical consistency. Thus, in the first paragraph of a recent paper, Milne, after asserting that "all the matter in the universe . . . must necessarily be taken into account in describing the motion even of a free particle", immediately announces that he fulfils this requirement by restricting his considerations to matter which obeys the cosmological principle. Again, he claims to deduce the Doppler effect from the manner in which the cosmological principle leads two or more observers to reconcile their clock readings, and hails this as evidence that the actual universe obeys the principle (indeed, Milne believes that God could not have made the universe otherwise). But obviously the Doppler effect could be detected if only one observer existed, so its derivation from the sociability of many must be fallacious. And so on.

This combination of paralysis of the reason with intoxication of the fancy is shown, if possible, even more strongly in Prof. P. A. M. Dirac's letter in NATURE of February 20 last, in which he, too, appears as a victim of the great 'Universe' mania. In essence the argument is this. Large numbers need an entirely different type of explanation from small ones (since the number of pure numbers is infinite the distinction is meaningless, but meaning seems to be irrelevant to these considerations). If, from an indefinitely wide choice, we select a certain unit of time ("say the unit e^2/mc^3"), the age of the universe according to one cosmological speculation is "about" equal to the square root of the number of protons in the universe according to another, and to the ratio of certain electronic forces. Hence we may take it as a "general principle" that *all* large numbers, etc. "In this way," adds Dirac, "we avoid the need of a theory."

The position must not be misunderstood. We are not dealing here with legitimate imagination transcending the temporary limits of exact demonstration. Nothing is easier and nothing is more deadly than to call for the stifling of all ideas that cannot here and now be proved of permanent value. But the question presented to us now is whether the *foundation* of science shall be observation or invention. Newton did not lack imagination, but he chose to examine pebbles rather than follow the Gadarene swine, even when the ocean before him was truth. Milne and Dirac, on the other hand, plunge headlong into an ocean of "principles" of their own making, and either ignore the pebbles or regard them as encumbrances. Instead of the induction of principles from phenomena we are given a pseudo-science of invertebrate cosmythology, and invited to commit suicide to avoid the need of dying. If anyone is uncertain about the place of imagination in science, let him compare Lord Rayleigh's discovery of argon with Dirac's discovery of the contemporary creation of protons which, according to *The Times*, "alters fundamentally our ideas of the structure of the universe and the nature of time".

Nor are we dealing with a mere skin disease which time itself will heal. Such ailments are familiar enough ; every age has its delusions and every cause its traitors. But the danger here is radical. Our leaders themselves are bemused, so that treachery can pass unnoticed and even think itself fidelity. It is the noblest minds that are o'erthrown, the expectancy and rose of the State which was lately so fair and in which there is now something so rotten that the very council of the elect can violate its charter and think it is doing science service. Five years hence we shall be celebrating the tercentenary of the death of Galileo and the birth of Newton. It rests with us whether we shall present to their memories a living monument of their own foundation or the resurrection hymn of their adversaries.

Rural England at the Royal Academy

MANY of the subjects which enlisted the enthusiasm of British artists fifty years ago, notably the historical and military, have faded out of modern exhibitions, but the scenery of the English countryside and coast retains its attraction, and is fully represented in this year's Academy. Landscape, and especially English landscape, is the principal subject of the water-colour paintings. These, relegated to a side gallery, are generally viewed after the eye has become attuned to the larger and stronger oil paintings.

It may be well, therefore, for those interested in landscape to visit the South Rooms first. Here are studies of the coast of Cornwall, the Cotswolds, the Sussex Downs, the Fens and Yorkshire moors, and examples of historic architecture such as the castles of Richmond, Bamburgh and Holy Island. The country church as the principal feature in East Anglian landscape is well treated in "Morston, Norfolk" (889) by Mr. Harry Morley. The seasonal aspect of the country landscape is beautifully rendered in Mr. E. W. Haslehust's "Winter" (764), where yellow reed beds are reflected in still water and backed by a dark thicket of bare boughs. "March Landscape" (949), by Mr. Victor W. Burnand, is a careful rendering of the tracery of elm boughs seen against the evening sky.

We come now to the oil paintings. The pictures entitled "The Evening Meal" (133) and "Pigs in a Barn" (332) by Mr. Frederick W. Elwell, are excellent studies of the interior of old timbered barns which, when the doors are open, give such opportunities for light and shadow. Mr. Fred Hall has a study of the same subject "In the Old Timbered Byre" (283). Mr. Edwin Byatt's "Mills at Outwood, Surrey" (164) shows the exterior view of roofs and gables of old barns and reminds us of the necessity for keeping in repair a picturesque feature, which when allowed to fall into dilapidation becomes a melancholy object in the countryside. It is perhaps from landscape paintings, rather than from direct observation, that the average person learns how decorative are the roofs and gables of old barns in the landscape of agricultural England. This is not entirely the average man's fault, for in actual fact there are few farmyards in which some part of the old roofs has not been repaired or replaced with unsuitable materials. The painter, however, can ignore these unsightly additions and represent the group of ridges and gables as they ought to be. There are a number of such studies in the present exhibition: "Afternoon on the Farm" (134) by Mr. Douglas P. Bliss, "Swanborough Pond" (266) by Mr. Vignoles Fisher, "A Sussex Lane in Winter" (650) by Miss D. H. de Carteret and "Essex Farmyard" (678) by Mr. Douglas Relf.

These studies lead one to consider the part of the landscape painter in the pressing task of preserving the scenery of rural England. The names of landscape painters figure very little on the councils of the numerous societies concerned in this important task, neither is it necessary that the exercise of their special talent should be interrupted by such activities. Rather should those engaged in the preservation of England's beauty study with care the outlook of the artist as embodied in contemporary exhibitions, and note particularly those artifices of composition by which disfigurements are passed over, and the yet more important devices by which the pictorial characters of a view are so enhanced as to carry the imagination from the actual to the infinite.

In the latter connexion, it is worth while to consider the titles which should be given to landscape pictures. The prevailing practice at the Royal Academy is to give the actual name of the locality or local feature without indication of the type of beauty which the picture embodies. Here and there, however, is a generalized landscape with an ideal title, as Mr. Reginald Hallward's "A Window on Eternity" (849). If the local names be retained in the case of a feature highly idealized, the artist provokes unfavourable comment; if it be not retained, the interest of association is lost. I venture on the suggestion that in such cases the picture should be given the title of the locality and the sub-title of the pictorial quality which it embodies. As a case in point I may cite the very interesting study of "Early Morning: Corfe Castle" (456) by Mr. Stanley Royle. An essential pictorial character of a castle set upon a hill is the verticality of the lines which carry to infinity the gradient of the natural feature. But the walls of Corfe, undermined and blasted by Cromwell, have in parts been left leaning over, and so the ruin has lost considerably in effect. But in this painting the artist has straightened up the walls, and in the houses and church below has emphasized the vertical lines. Here, therefore, it might be well to give a sub-title which would explain to the general public that departure from photographic representation, which is in this case more than justified by the ideal attributes the picture embodies.

One of the most perfect landscapes in this year's Academy is Mr. Oliver Hall's "Greenholme Bridge, Westmorland" (215). The curve of the single arch, the upward sweep of the approaching road, the reflection in running water and background of trees make a delightful grouping of forms, and the subject suits the tonality which characterizes this artist's work. Of the pictures of inland waters the large "River Scene" (510) by Mr. Algernon Newton, shows the sigma curve which is one of the essential beauties of streams which wander across the plain In the matter of coastal scenery we are once more indebted to Mr. Julius Olsson, among whose studies are "Opal Moon: Irish Coast" (317) and "The Storm Cloud" (169), an impressive picture of sea and sky.

The picturesque occupations of the countryside have received comparatively little attention, but two works at least deserve special attention, among pictures that by Miss L. Kemp-Welch of "The Lumber Team" (551) and among sculptures the very pleasing and unusual study "Lakeland Dalesman", equestrian statuette (1470) by Miss Ophelia Gordon.

The following portraits are of interest to the scientific fraternity, Sir Albert Seward (52) by Mr. Harold Knight, the late Brig.-General Sir Capel Holden, by Mr. P. Connard (158), Prof. T. B. Abell (290) by Mr. W. C. Penn, Mr. Sydney Evershed, by Mr. G. Harcourt (324), Sir George Hill, by Mr. J. Gunn (433), Sir Alexander Gibb (656) by Sir William Rothenstein, Sir Arthur Evans, charcoal drawing (1137) by Mr. Francis Dodd, and a marble bust of Sir Arthur (1451) by Mr. David Evans, a bust of Dame Helen Gwynne-Vaughan (1430) by Mr. Julian Allan and a stone bust of Prof. R. W. Reid (1435) by Sir W. Reid Dick.

VAUGHAN CORNISH.

Obituary Notices

Dr. J. K. Fotheringham, F.B.A.

JOHN KNIGHT FOTHERINGHAM, who died on December 12 of last year, was the greatest authority of his time on ancient chronology. The name Fotheringham is derived from the Manor and Castle of Fotheringay, held in the twelfth century by the royal family of Scotland as part of the Honour of Huntingdon in Northamptonshire. Mr. Walter de Fodringaye was one of the executors of Devorgilla, Lady of the Manor and wife of John de Baliol in 1289, and was appointed by her as the first principal of Baliol (Balliol) College, Oxford. By their close connexion with the House of Baliol, some of the Fotheringay family settled in Scotland at the end of the thirteenth century and the name was changed to Fotheringham. One William Fodringhay had a charter from David II of lands in Aberdeen and Banff. In 1296 Hugh de Foderingaye of Perthshire and Roger, vicar of Kilmuir in Ross-shire, did homage to Edward I. Duncan, Bishop of Dunkeld, granted Fordell, County Perth, to Walter de Fotheringham in 1340.

The family has, therefore, a long Scottish ancestry. They became Presbyterians at the Reformation. Dr. J. K. Fotheringham's father was born at Dunbarrow Bridge, and was minister of Glanton Presbyterian Church, Northumberland, in 1859–65, and of Tottenham Presbyterian Church, Middlesex, in 1865–1905; he was moderator of the Presbyterian Church of Scotland in 1912. John Knight Fotheringham was born at Tottenham in 1874, one of three brothers. He was a delicate child, and had indifferent health during his whole life. The inheritance of his remarkable genius must be partly attributed to his maternal ancestry; his mother was Jane Ross, also descended from an ancient Scottish family; her father was master of the Lancasterian School at Tottenham, and she taught at that school. He was educated at a school in connexion with the Tottenham Presbyterian Church and then at the City of London School, where he came under the instruction of Dr. Abbott, the headmaster. Under Abbott and Rushbrooke he received a sound classical training and entered Merton College, Oxford, in 1891 with a leaving scholarship. At Merton he obtained a first in Greats in 1896 and then proceeded to obtain a first in Modern History in 1897. Magdalen College gave him a Demyship, 1898–1902; he attended the British School in Athens for one year, settled in Oxford and became a coach. Magdalen College elected him to a research fellowship in 1909. He became reader in ancient history, University of London, 1912, and was a lecturer in classical literature at King's College, 1904–9, lecturer in ancient history at King's College, 1909–12.

About 1898, Fotheringham began the serious study of mathematics and astronomy, and made such astonishing progress that in 1908 he was able to make a valuable correction to the work of Ginzel, Nevill and Newcomb on eclipse calculations. He was made assistant at the Observatory at Oxford in 1918. About 1910 he became interested in Babylonian astronomy, and I then made his acquaintance; from that time until his death we collaborated constantly. In the meantime, he had been applying astronomy to Greek chronology, and had produced fundamental results. He now began to apply Babylonian astronomy to still earlier chronology and attained the undisputed position of the greatest living authority in these matters. The University of Oxford, therefore, created for him a post as reader in ancient astronomy and chronology in 1925 and he was elected to the British Academy in 1932.

It will be seen that the mental range of this scholar probably exceeded that of any one of his contemporaries in any land. An excellent classical scholar, a man of wide reading in modern history, an astronomer of great originality, a brilliant mathematician, and a specialist in ancient history—these are his attributes. Moreover, he was regarded as an authority on Presbyterian Church policy and was a devoted layman and elder.

The first contribution of Fotheringham to learning was an edition of the text of Jerome's version of the "Chronicle of Eusebius" (1905). The Bodleian MS. together with two others (Undine and Paris) is reproduced in collotype prefaced by a history and palæographical examination of all the extant manuscripts. For this work he visited many European libraries. In 1923 appeared his printed Latin text of the "Chronici Canones" of Eusebius with a complete *apparatus criticus*, and Latin introduction. It is obvious that this work of Eusebius on the *fila regnorum* or lists of reigns in Jewish, Persian, Assyrian, Greek and Roman history with historical comments was of fundamental interest to him as a student of ancient history; the tale that he took up this work because his birthday fell on August 14, a day dedicated to a Saint Eusebius, is surely apochryphal. In 1906 appeared vol. 11 (1801–37), second edition 1911, of Longman's "Political History of England", but henceforth his life was to be almost entirely devoted to astronomy and its application to ancient history. Here he was destined to make contributions to science on which his great fame will for ever rest.

Fotheringham edited the fragments of Cleostratus with a critical discussion of his importance as the first astronomer to introduce the signs of the zodiac into Greek science, together with the eight-year cycle of intercalation. In this work he combined a knowledge of philology with astronomy so as to enable him to clear up the meanings of several Greek words and to interpret passages which had baffled the greatest classical scholars. Several articles were devoted to the date of the Crucifixion, or the problem, "In what year between A.D. 27–34 did Nisan 14 or

15 fall on a Friday". His tables for the visibility of the new moon enabled him to place this problem on a more scientific basis, but he never came to a conclusion which he proclaimed infallible. In his last article he prefers A.D. 33, April 3.

In 1915 Fotheringham published a very learned work on Marco Sanudo, the Venetian prince who conquered the whole of the Grecian Archipelago in 1205–6 for his native city in wars with Genoa. To do this piece of work he had to use Italian, Byzantine Greek and French sources. He showed himself master in this department of medieval history, a strictly philological investigation. But astronomy was claiming more and more of his attention, particularly the history of that subject, and he was naturally drawn to Babylonian astronomy. I supplied him with the texts of the observations of the risings and settings of Venus during the reign of Ammizaduga, tenth king of the First Babylonian Dynasty. The book which we published together, "Venus Tablets of Ammizaduga", contains his *opus magnum*. I cannot enter into details here, but suffice it to say that he and his colleague Carl Schoch undertook to construct tables by which the new moons and risings of Mercury, Venus, Mars, Jupiter and Saturn can be fixed back to 3507 B.C. in the case of the moon, 2099 Mercury, 2999 Venus, 2148 Mars, 2153 Jupiter, 2123 Saturn. By elaborate astronomical control of the calendar and by the Venus tables, Fotheringham's calculation for the sixth year of Ammizaduga at 1916–1915 B.C. was agreed to by Schoch after long discussion; Schoch, recognized as the most brilliant constructor of historical planetary tables, at first opposed this calculation, but was finally convinced. (So far as I know, astronomers were convinced by Fotheringham's work, with the exception of Neugebauer.)*

Fotheringham also devoted much time to the work of the Babylonian astronomers Naburianos and Cidenas, whom he regarded as the principal sources on which Greek astronomy was founded. In the last months of his life he made a brilliant interpretation of figures on Babylonian astrolabes which had baffled Assyriologists to the present day. He studied the voluminous publications of Greek astronomical texts, "Catalogus Codicum Astrologorum Græcorum", and was able to prove that much of it was borrowed from Babylonia.

Fotheringham was now recognized as a man of unique knowledge; in fact, no man living combined his immense classical knowledge with astronomy and chronology. His fame spread in intellectual centres all over the world and his correspondence was heavy. He left a minute catalogue of all his books and articles, together with a list of all the inquiries he received on chronology and astronomy. The list of inquiries runs to more than 350, and includes most of the eminent names of archæologists of the last three decades in all lands. This notice is only a very restricted résumé of the work which J. K. Fotheringham accomplished. The printed testimonials which he submitted from various astronomers when he stood for the Savilian professorship at Oxford fill 34 pages. One of them states concerning his work on the secular acceleration of the sun and moon, "Fotheringham's theory is the only one which definitely solves the problem and means the death blow to the gravitation theory (as applied to eclipses) and will be the theory of the future", and this scholar pronounced Fotheringham to be the most brilliant mathematical astronomer of his age. He had a profound influence in Germany and America; in fact, he was far better known abroad than he was in Great Britain. I must for my own part assert that I was always fully aware of his almost unlimited ability. His death has completely deranged my plans. He was a typical Oxford product, modest, accurate and profound. One can readily believe after working with him more than twenty-five years that he was never angry about anything in his life. Many were his disappointments in academic promotion, and worst of all he suffered constantly from poor health. All these things he bore like a Christian gentleman, a title which gave him more satisfaction than any other. S. LANGDON.

An astronomical correspondent writes as follows:

Dr. J. K. Fotheringham's interest in astronomy developed from the study of ancient chronology. In order to be able to study astronomical chronology he took some lessons in spherical trigonometry and elementary mathematical astronomy from the late Prof. H. H. Turner, and afterwards received some further help in the use of lunar tables and the calculation of eclipses from Prof. J. B. Dale, of King's College, London, and Dr. P. Cowell, superintendent of the Nautical Almanac Office. With this modest preparation for astronomical studies, he proceeded to write a series of papers, in which his knowledge of ancient chronology had full scope, which are of great astronomical importance. In these papers he discussed the occultations of stars by the moon preserved in Ptolemy's "Almagest", the equinox determinations of Hipparchus, and ancient observations of solar and lunar eclipses. The result of these investigations was to establish that the sun has a secular acceleration of 3·0″ per century per century, and the moon has a secular acceleration of 21·6″ per century per century. Lunar theory predicts a secular acceleration for the moon of 12·2″. The residual acceleration, 9·4″, for the moon, and the whole of the secular acceleration of the sun cannot be accounted for by gravitational theory. It is now generally accepted that these secular accelerations are attributable largely, if not entirely, to the action of tidal friction, more especially in narrow seas such as the Irish Sea and the Bering Straits.

From these studies, Fotheringham was led on to the study of the discordances between the observed positions of the moon and the positions computed from pure gravitational theory. Newcomb had allowed for the major discordances by the introduction of an empirical periodic term. This so-called "Great Empirical Term" was incorporated by Brown into his "Tables of the Moon". But there remained minor fluctuations, which showed some correlation with the departures of the sun, Mercury and Venus from their predicted positions. Fotheringham made a careful analysis of the departures of the moon and sun from pure theory, and showed that there was a fairly constant ratio between the departures for the two bodies, the explanation of which is to be found in fluctuations in the earth's rate of rotation. Though other investigators were working on the same problems at the same time, Fotheringham's contribution was an important one.

---

* Neugebauer's objection to Fotheringham's dating of the First Babylonian Dynasty seems to be subjective and unscientific, for he himself adopted Fotheringham's values for the acceleration of Venus and the moon

In a further paper, Fotheringham made a study of precession, galactic rotation and equinox correction, in which he made a determination of the rotation of the galaxy, and revised the values of the precessional constants. This paper lost some of its importance through the discovery by Oort in the following year of the differential rotation of the galaxy. From this paper Fotheringham was led to the investigation of the mass of Venus. He believed that he had established that there was a fluctuation in the mass of Venus. These results have not been accepted by astronomers. Fotheringham was apt to be led astray by his failure to appreciate the value of observations and the systematic errors to which they were liable. This was due to his lack of any observational experience and to the limitations of his astronomical knowledge. That he was able to obtain the results that he did with so inadequate a training is greatly to his credit.

Other astronomical work of Fotheringham's included a study of the earliest visibility of the moon to the naked eye, which is of chronological importance because, in both the Babylonian and the Jewish calendars, the beginning of the month was fixed by observation of the moon; a restoration of the calendars of Meton and Calippus; discussions of the new star of Hipparchus and of the dates of the birth and accession of Mithridates. He also made a contribution to astronomical history in a monograph on Cleostratus, in which a complete text of the fragments of his work was given, and the nature of his contributions to astronomy was discussed.

WE regret to announce the following deaths:

Dr. J. J. Davis, curator of the Herbarium, University of Wisconsin, known for his work on parasitic fungi, on February 26, aged eighty-four years.

Dr. S. F. Grace, senior lecturer in applied mathematics in the University of Liverpool, author of works on hydrodynamics and tides, on April 30, aged forty-one years.

Prof. E. Perroncito, formerly professor of parasitology in the University, and professor of general pathology and director of the Royal School of Veterinary Medicine, Turin, aged eighty-nine years.

Prof. Stephen Soudek, professor of applied zoology in the Agricultural College, Brno, known for his work on pests of agriculture and forestry, on February 20, aged forty-six years.

News and Views

Magnetic Disturbances and Auroras

As reported in NATURE of May 1, p. 752, considerable magnetic disturbance, presumably related to an active region of the sun containing some big sunspots, began on April 24, and this terrestrial disturbance or series of disturbances was continued until about April 29^{d} 0^{h} U.T. The activity, as recorded at the Greenwich magnetic station at Abinger, includes four distinct disturbances or 'storms', of which the most active periods and extreme ranges in horizontal force have been kindly supplied by the Astronomer Royal, as follows:

April 24^{d}	21^{h} to April	25^{d}	2^{h} U.T.	280γ
25	16	26	1	300
26	18	27	5	395
27	19	29	0	> 305

The greatest ranges at Abinger over the whole period of disturbance were 50′ in declination, 500γ in horizontal force and 355γ in vertical force.

IN a letter addressed to the Editor, Father J. P. Rowland, *S.J.*, director of the Stonyhurst College Observatory, directs attention to these four storms and suggests that the last, which was of longest duration and produced the most rapid oscillations in the traces, might perhaps be attributable to the largest of the groups of sunspots (with central meridian passage on April 24·6) which extended some 14° in longitude on the sun's surface. The ranges of the magnetic elements recorded at Stonyhurst (about 200 miles north-north-west of Abinger) during this period of magnetic activity were 93′ in declination and >620γ in horizontal force, thus exceeding any recorded ranges at Stonyhurst since February 1929. In another letter, Mr. J. McWilliam describes a notable display of the aurora which he saw about midnight when ten miles south of Grantham and which was still visible, though less striking, when seen from Sheffield about two hours later. The display was seen even though there was brilliant moonlight. (As previously mentioned, on p. 752, Mr. Hawke reported this display in *The Times* of April 27, and information of another about midnight on April 26–27 comes from Mr. Housman, of the Seaton Observatory, Workington.)

THE Royal Observatory, Greenwich, was informed by the British Broadcasting Corporation that a brilliant aurora was reported from Halifax, Nova Scotia, on the night of April 27–28. During this last period of magnetic activity, there was for several hours a complete dislocation in short-wave wireless communication between Great Britain and Canada. In point of fact, throughout the period, April 24–29, short wave communication was often impossible on this channel, other channels being variously affected but to a less extent. Cable and Wireless Ltd. also report during the same period frequent interruption due to earth currents in cable circuits operating between Great Britain and Newfoundland and vice versa. On the morning of April 28 between 1^{h} and 7^{h} and again from $10\frac{3}{4}^{h}$ to $12\frac{3}{4}^{h}$ U.T., the earth currents on this circuit were so severe that trans-atlantic communication by cable was impossible.

University of London's Institute of Archæology

ON April 29, the Earl of Athlone, Chancellor of the University of London, formally declared open the Institute of Archæology, housed for the present in St. John's Lodge, Regent's Park, and unveiled wall-tablets to the memory of Mrs. Tessa Verney Wheeler, who was honorary secretary of the original Appeal Committee to collect funds for the foundation of the Institute, and of Mrs. Mary Woodgate Wharrie, a generous benefactor. The Chancellor was welcomed by Sir Charles Peers, chairman of the Committee of Management, and thanks were conveyed to him after the ceremony by the Right Hon. W. G. A. Ormsby-Gore, who was First Commissioner of Works when St. John's Lodge, as Crown property, was allotted to the use of the Institute, and Dr. R. E. Mortimer Wheeler, director of the Institute. Arrangements have been made for the tenure of the present premises for a period of years; but it is hoped that eventually quarters for the Institute will be found among the University buildings in Bloomsbury near the Historical Institute and the Institute of Art.

IT is usual on an occasion such as this opening ceremony to describe it as "epoch-making". In the present instance this term might be used with nearer approximation to the truth than is common. As was pointed out at the time, the proposal for an Institute of Archæology in the University of London was first made, the expansion of archæological investigation and the increased interest in the application of its results had made the provision of some such organization as a training ground a matter of urgency. As Sir Charles Peers said in welcoming the Chancellor, archæology, if one of the newest sciences, has the vigour of youth; and although in the nine years which have lapsed since the original proposal was formulated, progress towards meeting the requirements of archæological training may have seemed slow, it has been substantial. The Institute is already well on the way to providing in its library, its collections of antiquities and its training in methods of research the requirements which Sir Charles laid down as the minimum. Lord Athlone's reference to the present importance of Palestine in British field archæology not only emphasizes the value of the collection of Palestinian antiquities—the largest in existence outside Palestine—which the Institute owes to Sir Flinders Petrie and the generosity of the British School of Archæology in Egypt, but also, by endorsing his support of the appeal for a chair of Biblical archæology, afforded convincing testimony that in saying he regarded the ceremony he had just performed as the laying of a foundation stone rather than as a formal opening, he was expressing something more than a conventional compliment.

Celtic and Saxon Art in Early England

THE exhibition of photographs of stone crosses and other forms of Celtic and Saxon sculptural art in stone now on view in the Iron Age Gallery of the British Museum (Bloomsbury) is an indication of the remarkable wealth of this material still surviving, which, in its mass, is something of a revelation even to the expert. The indefatigable labours of the late Romilly Allen, Baldwin Brown and W. G. Collingwood, the last-named more particularly in the north of England, have made known to archæologists the extent and value of this class of evidence, especially as afforded by the stone cross, in the interpretation of racial and cultural movement in the early historic period of Britain; but the work of the survey initiated by the Department of British Antiquities of the Museum some eighteen months ago, in which the assistance of the layman and amateur student has been enlisted widely, has brought together a record of examples of the various classes of this art in the form of photographs, which is surprising. As a whole, it is claimed, probably with justice, that this collection of examples of Celtic and Saxon sculptural art is the finest in existence.

SOMETHING of the work which already has been accomplished by the survey is shown in a selection of the photographs, primarily of the stone crosses, but also including fonts, tympana, capitals and the like. Geographically, the area covered is England, with the 'Anglian' crosses of southern Scotland; but selected examples from outside England are shown for purposes of comparison. The Isle of Man and Ireland, important areas which are a study in themselves, naturally are not included. Special features have been made of photographs by John and Mrs. Piper, who have made an extensive collection of photographs of Anglo-Saxon and late Romanesque sculpture, of a group of sculptures from the West Riding of Yorkshire by Mr. J. E. Tetley and of a regional survey of Cheshire and Staffordshire, which is illustrated by distribution maps and a map prepared in collaboration with the School of Geography of the University of Liverpool, showing relation to forest clearance and habitation in the eleventh century.

Armagh Observatory

DR. E. M. LINDSAY, at present an assistant in the Harvard Observatory in Bloemfontein, South Africa, has been appointed astronomer at Armagh Observatory. This Observatory was founded in the year 1791 by Richard Robinson, Baron Rokeby, Archbishop of Armagh and a great benefactor of the city of

Armagh. The Primate gave as an endowment of the Observatory twenty acres of land close to Armagh, on which the Observatory is built, and the estate of Derrynaught, which he had bought out of his private means. He further provided for the salary of an assistant and the current expenses of the Observatory. The power of nominating and appointing the astronomer is reserved for the Archbishop of Armagh and Primate of all Ireland for the time being. The first astronomer of the Observatory was the Rev. Dr. J. A. Hamilton, who was succeeded in 1815 by the Rev. W. Davenport, and then, in 1823, by the Rev. T. R. Robinson, who held the post until his death in 1882—a period of more than fifty-eight years. The anemometer which bears Dr. Robinson's name was first put up on the roof of the Observatory in 1846, but meteorological observations had been commenced thirteen years earlier. Dr. J. L. E. Dreyer succeeded Dr. Robinson in 1882, and the next director appointed was Mr. J. A. Hardcastle, who, however, died in 1917 without having actually taken up the post. The Rev. W. F. A. Ellison became director in 1918 and occupied that position until his death at the end of last year.

Royal Institution: Annual Meeting

THE annual meeting of the members of the Royal Institution was held on Saturday, May 1. In the unavoidable absence of the president, the Right Hon. Lord Eustace Percy, the chair was taken by Major Charles E. S. Phillips, secretary and vice-president. In submitting the annual report of the Visitors to the meeting, the chairman referred to the satisfactory state of the membership, which has increased steadily in recent years, and which stands now, including honorary as well as full members and associate subscribers, at 1,055. The reconstruction of the Library and other rooms, which the Managers were forced to undertake when a large part of the building was found to be in an alarming state of disrepair, was completed in October. This work, which the accounts show had cost nearly £16,000 at the end of the year, and included the construction of a large new laboratory, has added greatly to the beauty and convenience of the house. Owing to the withdrawal of the direct current mains in Albemarle Street and neighbourhood, it has been necessary for the Institution to provide its own equipment for the supply of direct electric current. A large storage battery and two mercury arc rectifiers, supplied from the A.C. mains, have been installed. The output from the rectifiers has been specially smoothed, and is found to be sufficiently free from ripple for most experimental purposes. The battery is used for arc lanterns in the lecture theatre.

THE expenditure on these and other purposes has been largely met from the munificent bequest of the late Mr. Harry Brown, which, it is now reported, has amounted to more than £29,000. No. 19 Albemarle Street, adjoining the Institution's premises, recently purchased, has now been fully occupied. The two top floors are used for library and museum extension, and the lower floors have been let off for the present, producing income which is being devoted to research purposes. The accounts of the Davy Faraday Research Laboratory, in which the Institution's research expenditure is accounted for, show a deficit of nearly £2,000 on the year's working. The chairman was able to announce a generous Coronation year gift by the honorary secretary of the Laboratory, Sir Robert Mond, of a sum of money sufficient to meet the deficit. The following were elected to the various offices: *President:* The Right Hon. Lord Eustace Percy. *Treasurer:* Sir Robert Robertson. *Secretary*. Major Charles E. S. Phillips. *Managers*—Sir John Cadman, Sir James Crichton-Browne, Dr. Cecil H. Desch, Sir James Devonshire, Prof. A. C. G. Egerton, Lord Falmouth, Mr. J. S. Highfield, Mr. Arthur Jaffe, Sir William Larke, Mr. V. Warren Low, Sir Murdoch MacDonald, Mr. C. C. Paterson, Prof. J. C. Philip, Sir Thomas Purves and Admiral C. V. Usborne. *Visitors*—Mr. C. Cuthbertson, Prof. C. L. Fortesque, Dr. J. J. Fox, Captain A. C. Goolden, Prof. H. Hartridge, Mr. Emil Hatschek, Prof. F. L. Hopwood, Dr. R. Lessing, Mr. A. H. Levy, Mr. F. I. G. Rawlins, Mr. Russell J. Reynolds, Prof. H. R. Robinson, Dr. G. Shearer, Major W. S. Tucker and Colonel W. A. Vignoles.

Shakespeare's Universe

FOR his Friday evening discourse before the Royal Institution on April 30, Prof. J. Dover Wilson discussed "Shakespeare's Universe". To understand Shakespeare, he said, one must understand his universe—a very different one from that of Newton, and still more from that of Einstein. In his day the ideas of Copernicus and Galileo were just beginning to penetrate to the consciousness of the ordinary man, and did not become really influential until after the middle of the seventeenth century. Shakespeare lived in a universe which, first described by Ptolemæus of Alexandria in the second century A.D., held sway over men's minds throughout the Middle Ages and had thus served humanity for fifteen hundred years. The best picture of this universe in our literature is to be found in "Paradise Lost", for though Milton understood the new astronomy and actually refers in his poem to Galileo, whom he had met in Italy, he made use of the old scheme of ten concentric spheres with the earth at the centre. As the spheres revolved at different rates and with their own peculiar motions on one another, they made music which was known as "the music of the spheres"; the sound was inaudible to mortal ears. Shakespeare's description of this astral musical box is well-known. Thus the universe was a 'harmony'; and harmony is the master-key of Shakespeare's thinking, whether upon the world at large, upon human society, or upon man himself, man the microcosm which reflected the macrocosm in little.

MUSIC meant a great deal to Shakespeare. It had medicinal properties to which he often refers. Moreover, the man of harmony would be at once fond of music and a good citizen, because human society was thought of as a harmony also. What kept concord in man, in society and in the universe as a whole was order or degree, the virtues of which are celebrated by Ulysses in the long speech in "Troilus and Cressida" (1.3.84–124), which gives us Shakespeare's most elaborate and explicit statement of Elizabethan political philosophy. This correspondence between humanity and the starry universe was no mere poetical metaphor. In that day, the stars and the human race were thought of as intimately linked. Comets and eclipses were portents. Astrology, the study of the influence of the stars, was a most learned and elaborate science in which everyone believed. We have no right to condemn such notions as mere superstition. Men toiled at them, gave up their lives to them, as modern men of science do to science. The Elizabethans were as intellectual as ourselves, probably more intellectual. Three hundred years hence, will not our roads to truth seem as strange, as ill-directed as theirs seem to us ?

The Flow of Metals

PROF. E. N. DA C. ANDRADE delivered the twenty-seventh annual May Lecture before the Institute of Metals on May 5. Flow is most easily observed in the liquid state, but whereas there is a satisfactory theory of gases, and the structure of crystalline solids has been elucidated by the methods of X-ray analysis, very little is known of the actual behaviour of the molecules in the liquid state. Prof. Andrade has put forward a theory of liquid viscosity on the basis that the momentum is transmitted from layer to layer not, as in a gas, by the passage of molecules from one layer into the other, but by instantaneous association of the molecules when they touch, so that at any nearest approach two molecules share their momentum. On this basis, a formula can be derived which gives the viscosity of a simple liquid at its melting point, and another which gives the temperature variation of the viscosity. Molten metals are particularly suitable for experiments designed to throw light on this problem of viscosity, because they constitute liquids which consist of one kind of atom only, and they are not, in general, associated. The viscosity is conveniently measured by sealing up the molten metal in a sphere, suspended *in vacuo*, and observing the damping of the torsional oscillations of the sphere about a vertical axis due to the enclosed liquid. The method has already been used for the alkali metals, and is being extended to other metals. The flow of solids is, perhaps, at first sight, even more troublesome theoretically than the flow of liquids, for single crystals of metals exhibit plastic flow under very small stresses, whereas a perfect crystal should be strong, and also brittle. It cannot be said that there is any fully satisfactory theory of the flow of single crystals of metals, but a good beginning has been made. It is, of course, a far step from the single metal crystal to the polycrystalline metal of industry, but we know that any crystal boundary is likely to stop the propagation of a dislocation, or glide in general, and so will make the metal less weak and less liable to flow. Industry cannot, of course, wait for theory, but the only really satisfactory way to approach the problem of the strength of metals is by way of the single crystal.

Exhibition of Opals at the Geological Museum

A SPECIAL loan exhibition of Australian opals and other gemstones, from the collections of Mr. Kelsey I. Newman, has been arranged for this Coronation month at the Geological Museum in South Kensington. The exhibition comprises many of the most beautiful opals hitherto obtained from New South Wales, including the famous 'Flame Queen', a magnificent and unique stone reputed to be the finest specimen yet won from Australian opal fields. Most of the stones are 'black' opals from the Lightning Ridge field, New South Wales, where the gem occurs in fissures or joints in sandy sediments of Cretaceous age. Since the 'black' opals from this area first came into the market about 1908, more than a million pounds worth of these stones has been produced from Australian sources. A collection of Australian sapphires, principally golden stones, is also exhibited. These are from the alluvial deposits of Anakie in Queensland, from which locality stones to the value of £113,000 have been produced since 1921. Other temporary exhibitions at the Museum include a display of recent presentations of semi-precious and ornamental stones presented by H.M. Queen Mary; and a small exhibit on the geology and history of the Coronation Stone, which is compared to Old Red Sandstones of similar petrography from the neighbourhood of Scone in Perthshire

Coronation Planting Schemes

IN order to encourage planting and the beautifying of the countryside as one aspect of Coronation celebrations, the Coronation Planting Committee has been formed under the presidency of the Marquess of Lothian, with an office at 68 Victoria Street, Westminster. The Committee is fully representative of practically all associations which aim at preserving the beauty and natural scenery of Great Britain. Its objects are explained in a pamphlet entitled "For King and Countryside: Towards a more Beautiful Britain", and it may be recalled that the scheme was launched at a meeting in Guildhall on November 26, 1936. Other booklets have now been published dealing with the village and how to make it beautiful, commemorative tree planting, design of allotment areas, play-parks, window-box gardening, etc. The Committee has also issued a leaflet with suggested forms of competitions for village communities, in order to foster pride in the village, floral displays and a care for trees. It is proposed to prepare a volume recording all the amenity schemes undertaken throughout the country in commemoration of the Coronation. The Committee's aims should make a wide appeal especially to those bodies which feel that transitory decorations need to be supplemented by permanent records of the occasion.

Causes of the United States Floods

THE unprecedented floods of the Ohio River in January of this year are the subject of a paper by Prof. C. F. Brooks and Major A. H. Thiessen in the *Geographical Review* of April. Floods may occur in the eastern United States at any time of the year, for there is always an extensive warm water surface near by to provide great volumes of water vapour, and not far distant are cold surfaces to furnish moving wedges of cold air to elevate the tropical air. Outstanding floods, however, occur only where a persistent high pressure area over the western Atlantic sends air currents inland for days in succession, and a winter high pressure area over the central or northern interior of the United States sends cold air southward or south-eastward. Along the front between the masses of polar air and the tropical air continuous ascent of the warmer air occurs with resultant heavy rains. In an ascent of two miles, three quarters of the water vapour in the warm air is precipitated. The authors calculate that a mass of air, nearly saturated at 77° F. over the Caribbean Sea, chilled over land in middle latitudes to 68° F., would contain about 80,000 tons of water vapour for every square mile of surface. If this were forced upward to a height of two miles the rainfall would be 0·8 inches. This would probably occur in one day with wind at a velocity of four to eight miles an hour. Since the average speed of the tropical air mass is 30 - 40 miles an hour, it is easy to understand the occurrence of torrential rains of some five inches a day.

The Czechoslovak National Research Council

THE Czechoslovak National Research Council, which is affiliated to the International Council of Scientific Unions, was founded in 1924 originally with ten (now twenty) sections and with a membership limited to two hundred. It includes all branches of science as well as mathematics, medicine and philology, and at first its activities were mainly concerned with establishing good international scientific relations. To-day, its aims are specially directed towards the promotion and financial support of scientific research in general. In this it has the co-operation of the Czechoslovak Ministry of Education, and its work assumed considerable importance when the economic depression began to impede both international relations and the prosecution of pure researches. In 1935, a Masaryk Foundation for the endowment of scientific work was established with an initial capital of three million crowns (about £25,000 at the time) to ensure that adequate financial assistance was available for the purchase of apparatus needed for research purposes, for the publication of scientific books and memoirs and for travelling scholarships. These funds of the Czechoslovak Research Council are intended especially for the support of promising young men of science in Czechoslovakia, irrespective of their nationality or creed. In the annual report for 1936 it is mentioned that the Council awarded travel fellowships to ten students and granted 193,000 crowns (about £1,400) towards the publication of some fifty noteworthy scientific works and for acquiring apparatus. During 1937, thirteen students have been sent abroad to continue their studies. The president of the Council is Prof. B. Němec, and the general secretary, Prof. F. Ulrich, whose address is Prague II, Albertov 6.

Solar Heaters in California

THE large amount of sunshine available in California during the summer has led to the extensive use of solar water-heating apparatus for domestic purposes, and a detailed account of their construction and use is given by Prof. F. A. Brooks of the Berkeley Agricultural Experiment Station in *Bulletin* 602 of the College of Agriculture. The solar absorber consists of a zigzag pipe in a glass-covered, thermally insulated box placed on a sloping roof facing south, in front of attic windows so that the glass may be readily cleaned. An insulated pipe leads from the top of it to the top of an insulated hot-water tank in the attic roof and another pipe from the bottom of the absorber to the bottom of the tank. In the winter the solar absorber is supplemented by a coil in the range connected to the tank in the same way. The useful life of such an installation is fifteen years, and the cost per 1,000 British thermal units of solar heat absorbed is about one ninth of a cent.

Prof. M. N. Saha, F.R.S.

WE have received a pamphlet summarizing the scientific work of Prof. M. N. Saha, who, as indicated in NATURE of March 13, has recently been elected president of the National Institute of Sciences of India for the current year. In addition to his theory of stellar spectra, which in fact was begun in India before he came to England, Prof. Saha has made experimental researches with the object of confirming the theory and has produced papers on selective radiation pressure, active nitrogen, spectroscopy and atomic and molecular structure, the colours of inorganic salts, thermodynamics, Dirac's theory of the electron, and upper atmospheric phenomena. He has also written treatises on heat and on modern physics, and has promoted much research on molecular spectra by students working under him.

Association of Teachers in Technical Institutions

THE twenty-eighth annual Conference of the Association of Teachers in Technical Institutions will be held at Coventry on Saturday May 15-18 under the presidency of Mr. W. E. Park. All meetings will be held in the Technical College, Coventry. Resolutions to be discussed by the Conference comprise the following: courses of training for technical teachers; tenure of university scholarships; leave of absence for technical teachers; assistance to teachers attending short courses of the Board of Education; co-operation in technical education; the Factory Act; day technical classes. Further information can be obtained from the Secretary, A.T.T.I., 29 Gordon Square, London, W.C.1.

Congress on Spectroscopy

A FIFTH spectroscopy conference will be held at the George Eastman Research Laboratories of the Massachusetts Institute of Technology on July 19–21, repeating to a considerable extent the type of conferences held during the past four summers. A programme of papers and discussions is being prepared on analysis of materials by the emission spectrum, absorption spectro-photometry, photographic photometry, biological and chemical effects of spectral radiation, and industrial applications of spectroscopy. The usual summer courses on practical and applied spectroscopy will be offered at the Institute between June 14 and July 24. Further information can be obtained from Prof. G. R. Harrison, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts.

The Partial Transit of Mercury on May 11

ON May 11 next, a partial transit of the planet Mercury across a narrow segment of the sun's disk occurs between $8^h\ 31^m$ and $9^h\ 30^m$ U.T., the maximum ingress being only 7·3″. The partial transit will not be visible from Great Britain but can be seen generally from over southern Asia, the Philippine Islands, Western Australia, the Indian Ocean and Central and Southern Africa. The "Nautical Almanac" for 1937 on p. 519 gives the local circumstances for several places from which the partial transit may be observed. Dr. A. C. D. Crommelin has pointed out that it is important for observers in the southern hemisphere to watch for the appearance of any arc of sunlight around the limb of the planet (projected on the sun's limb) due to a Mercurian atmosphere. Such an arc has been observed in the case of Venus but never with certainty in the case of Mercury Although this partial transit is not visible from Great Britain, Dr. Crommelin suggests further that spectroscopists in Great Britain may see Mercury projected on the chromosphere; the nearest approach to the sun is at $9^h\ 0^m$ (Summer Time $10^h\ 0^m$) at position angle 154° from the north point.

Announcements

SIR FREDERICK GOWLAND HOPKINS has been awarded the Harben Gold Medal of the Royal Institute of Public Health. The Medal is awarded triennially, under a trust created by the late Sir Henry Harben, to the person, irrespective of nationality, who, in the opinion of the Council of the Royal Institute of Public Health, has rendered the most eminent services to public health. Past recipients of the Medal include: Louis Pasteur, John Simon, Max von Pettenkofer, Lister, Koch, Metchnikoff, Behring, Roux, Ronald Ross, Sir Charles Sherrington, and Kitasato.

THE Council of the British Scientific Instrument Research Association has accepted with regret the resignation of Dr. Harry Moore, who, since the retirement of the late Sir Herbert Jackson, in July 1933, has been the director of research of the Association. The period during which Dr. Moore has been in charge of the Association's research work has been one of great activity and usefulness to the British scientific instrument industry. Dr. Moore's particular knowledge and experience of the research needs of industry will not be lost, as he has accepted an appointment in which he will direct the research work of an industrial corporation. Mr. A. J. Philpot has been appointed to succeed Dr. Moore as director of research.

DR. E B. WORTHINGTON, demonstrator of zoology in the University of Cambridge, has been appointed director of the Laboratory at Wray Castle on Lake Windermere of the Freshwater Biological Association of the British Empire.

DR. N. K. ADAM will open a discussion, under the auspices of the University of London Animal Welfare Society, on "The Destruction of Sea-Birds by Oil Waste" in the Chemistry Theatre at University College, London, on May 10 at 5.30. Admission is free.

SIR JOHN RUSSELL will deliver the thirty-eighth Bedson Club lecture at Armstrong College, Newcastle-upon-Tyne, on May 21, at 6.30. The subject of the lecture will be "Chemistry in Modern Food Production".

THE ninth International Congress for Psychotherapeutics will be held at Copenhagen on October 2–4. The official languages are English, French and German. Further information can be obtained from the president, Prof. C. G. Jung, Kussnacht, Zurich.

AN International Congress is being organized by the International Abolitionist Federation to be held in Paris from May 20–22, when the problem of prostitution will be studied from the legal, medical and moral points of view. Further information can be obtained from the Secretariat of the Federation, 8 rue de l'Hôtel de Ville, Geneva.

THREE fellowships in psychiatry, each of the value of £300, are offered for half-time work at the London Child Guidance Clinic, 1 Canonbury Place, N.1. Further information can be obtained from the Secretary of the Council, Woburn House, Upper Woburn Place, London, W.C.1.

WE regret that in a short notice of "The Hair in Health and Disease", by Mr. Edward Lawrence, in NATURE of May 1, the statement was incorrectly made that the author was a barber. Mr. Lawrence has been a fellow of the Royal Anthropological Institute and member of the Geologists' Association since 1885. He is described on the title page of his book as scientific correspondent of the *Hairdressers' Weekly Journal* and author of "Savage Life and Custom", etc., and his works include, he informs us, "Over 400 contributions on folk lore, antiquarian and other subjects to *Hairdressing Fashions* and *The Hairdressers' Weekly Journal*".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 805.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

An Attempt to Detect the Disintegration of the Neutron

EXPERIMENTS performed by Kikuchi, Aoki and Husimi[1] were interpreted as evidence for the disintegration of the neutron. When neutrons from a heavy water target bombarded by deuterons were passed through various substances, electrons having energies up to 1 MeV. were observed, and it was suggested that these could be accounted for by the reaction :

$$n \rightarrow p + e + 1 \text{ MeV.}$$

The probability that this should happen during the interaction of a neutron with the field of any given nucleus was expressed in terms of a collision cross-section, varying from about 10^{-24} sq. cm. for heavy nuclei to about 10^{-25} sq. cm. for light nuclei.

We have failed to confirm this in two different types of experiments. The first set of experiments were made to detect the proton and the electron starting from a point in the gas in a Wilson cloud chamber. Experiments to determine the statistics of the neutron-proton collision were in progress, and the same apparatus was used in these experiments. A description of the apparatus and the method of measurement will shortly be published elsewhere[2]. Oxygen at about three atmospheres pressure was used in the chamber, so that any proton recoils obtained would be due to the water vapour. This number could be estimated from the previous experiments with the apparatus. 150 photographs were taken, and the number of recoils observed was 0·6 per expansion, and this is the number to be expected from the hydrogen in the water vapour. In no case was there an electron track starting at the beginning of a proton track. The condition of the chamber was such that electron tracks due to the X-radiation from the accelerating tube were clearly visible. The ranges of the recoil protons were measured, together with the angles they made with the direction of the source. In most cases these were consistent with the assumption that they were due to proton recoils from 2·5 MeV. neutrons. The number of pairs of proton and electron tracks to be expected, if the neutron disintegrates into a proton and an electron with a collision cross-section of 10^{-24} sq. cm., is 30 per expansion. Hence we conclude that the cross-section for the disintegration of the neutron is at least 1,000 times smaller than that suggested by Kikuchi

The second experiment was an attempt to observe by a coincidence method the simultaneous production of a proton and an electron from a neutron. An intense source of neutrons was obtained by bombarding a target of $Al(OD)_3$ with deuterons accelerated through a potential of 70 kV. The ion source was of the type described by Tuve, Hafstead and Dahl[3]. Later, a still more intense source was obtained by using a heavy water target cooled with liquid air. By comparison with a standard radium-beryllium source, using a boron trifluoride chamber, the strength of the neutron source was found to correspond to about 600 millicuries. A small argon-filled ionization chamber connected to a linear amplifier was used to detect the protons produced in the argon or in the walls of the chamber, and a Geiger counter was used to detect any electrons produced in the chamber. The front of the ionization chamber was covered by an aluminium window of 2 cm. air equivalent stopping power, and was placed about 5 mm. from the front of the Geiger counter. From the geometry of the apparatus, it was estimated that 1/10 of any sufficiently energetic electrons produced in the ionization chamber would enter the Geiger counter. A 'scale of two' thyratron counter was arranged to count coincidences between the kicks in the two counters. The centre of the ionization chamber was placed 4–5 cm. from the neutron source.

The number of coincidences observed with and without the interposition of a brass sheet, capable of stopping the electrons, between the two counters were compared. 72 coincidences were observed without the brass and 70 with it present. The experiment therefore gives no evidence that the neutron disintegrates into a proton and an electron. From the dimensions of the apparatus it is estimated that the cross-section for the disintegration of the neutron, if it takes place, is less than 3×10^{-26} sq. cm.

Thermal Precipitation of Radioactive Substances

THE usual method of separating solid radioactive particles from the gas phase is precipitation by an electric field. This is the classical procedure for the collection of the active deposit of radon and thoron, and can also be applied to artificial radio-elements, such as radio-arsenic prepared in arsine by neutron bombardment[1]. The process depends on the presence of an electric charge on the particles ; and unfortunately, at least in the case of artificial radio-elements produced by slow neutrons, such a charge does not necessarily exist. It is, therefore, of practical as well as theoretical importance to seek other means of concentrating the radioactive particles. One promising means which we have tried is 'thermal precipitation', which is based upon a very simple principle.

A heated body in a cooler gas is surrounded by a dust-free space, a phenomenon already observed by Tyndall. Recently, it has found practical application as a means of collecting dust samples from air; for when a gas stream is forced to pass within the dust-free space of the hot body, whatever dust it may contain is deposited on the unheated surface facing the heated body[2]. So far, the method seems to have been tested only on particles visible under the microscope; but as between the limits of diameter of at least 20 μ and about 0·2 μ the efficiency of the method does not depend on the size of the particles[3], it seemed promising to apply it to the collection of the small aggregates composed of radioactive substances. The following account will show that our experiments were successful.

We sent a slow stream of air, carrying radon in equilibrium with its active deposit, through a small thermal precipitator consisting of a wire (0·25 mm. diameter) between two parallel microscopic cover-slips each held 0·1 mm. from the wire. If the wire were at the same temperature as the glass plates, only the usual very slight, and perfectly homogeneous, contamination of the plate by the active deposit could be observed. If, however, the wire were heated to a temperature of 200° C., the active deposit was precipitated on both glass plates, opposite the wire, in the form of a narrow straight line. This we verified by measurement of the activity of the plate in a Geiger-Müller counter, using a lead screen with a slit which was moved over the surface of the glass parallel to the former position of the wire, and by photographing the active deposit on the cover-slip by fixing the latter at a very small distance from a photographic plate. The possibility of preparing radioactive sources not on a wire but on a plate, and nevertheless highly concentrated in a narrow line, may conceivably be of great use in radioactive work.

The efficiency of the precipitation was tested by inserting an electric condenser immediately behind the thermal precipitator. It was found in two experiments that when the precipitator wire was heated, 67 per cent of the deposit formerly collected in the condenser remained in the thermal precipitator. It is probable that after establishing the best conditions of temperature and geometrical arrangement, even a higher percentage of the radioactive particles would be caught; but only a closer study will reveal whether there is a lower limit for the size of particles which can be precipitated thermally.

We hope now to apply the method of thermal precipitation to the collection of artificial radio-elements.

A Note on the Theory of β-Radioactivity

The ratio between the probability of absorption of a K-electron by a nucleus and the total probability of emission of a positron by the same nucleus can be calculated on the hypothesis put forward by Fierz[1] that the interaction term in the neutrino theory contains the five possible invariants. Let J_K be these invariants, obtained by scalar products from combinations of Dirac's matrices. If one puts $H_\beta = \sum\limits_K C_K J_K$, the probability of the process of β-radioactivity is proportional to $|H_\beta|^2$. Let $\vec{p}_\nu$, $\vec{p}_{el}$, W_{el} be the momentum of the neutrino, that of the electron, and the energy of the latter, these quantities being measured in units of mc and mc^2 (m = mass of the electron; c = velocity of light). If the atomic number Z of the reacting nucleus is small, one obtains for the probability $P(W)dW$ of the emission of an electron (a positron), the energy of which lies between W and $W + dW$:

$$(1)\qquad P(W)dW = k\Big[C_1^2 + C_2^2 + 3C_3^2 + 3C_4^2 + \frac{\vec{p}_\nu \cdot \vec{p}_{el}}{p_\nu \cdot W_{el}}\left(C_1^2 - C_2^2 - C_3^2 + C_4^2\right) \pm \frac{1}{W_{el}}\left(C_1C_2 + 3C_3C_4\right)\Big]\, p_\nu^2 p_{el} W_{el} dW_{el},$$

where k is a constant. The energy p_ν of the neutrino is equal to the difference W_0 between the energies of the initial and the final nucleus, minus the energy W_{el} of the emitted particle. The signs ± in (1) refer to an electron or a positron.

Let us put $C_1^2 + C_2^2 + 3C_3^2 + 3C_4^2 = A$, $C_1C_2 + 3C_3C_4 = B$. The C_i's are real numbers, whence $|B| < A$.

We can calculate the total probability of emission of a positron, the energy of which lies of course between 1 and W_0, and also the probability of absorption of a K-electron, which is obtained from the same relation (1), only with a different energy balance. A similar calculation has already been made for different interactions[2]. After integrating over the angles, one obtains for these probabilities $\int_1^{W_0} P(W_{pos})dW_{pos}$ and P_K respectively; the ratio λ of the latter to the former can be obtained experimentally. This ratio is here equal to

$$\lambda(W_0,Z) = \frac{P_K}{\int_1^{W_0} P(W_{pos})dW_{pos}} = 10^{-4} Z^2 \frac{1 + C}{\zeta_1(W_0) - C\,\zeta_2(W_0)},$$

where the constant C is equal to

$$C = B/A, \quad |C| < 1.$$

The functions $\zeta_1(W_0)$ and $\zeta_2(W_0)$ are the following:

$$\zeta_1(W_0) = \frac{137^2}{240\pi} \times \frac{(4W_0^4 - 18W_0^2 - 16)\sinh\cosh^{-1}W_0 + 30W_0\cosh^{-1}W_0}{(W_0+1)^2},$$

$$\zeta_2(W_0) = \frac{137^3}{240\zeta} \times \frac{(10W_0^3 + 65W_0)\sinh\cosh^{-1}W_0 - (60W^2 + 15)\cosh^{-1}W_0}{(W_0+1)^2}.$$

It should be noticed that for all values of W_0 (that is, $1 < W_0 < \infty$), one has $\zeta_2(W_0) < \zeta_1(W_0)$.

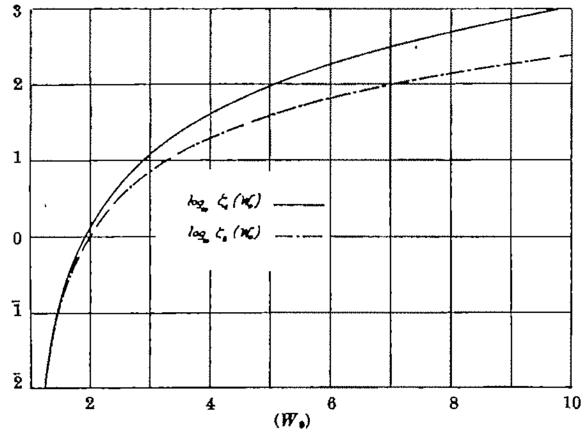
[3] See Green, H. L., *Trans. Faraday Soc.*, **32**, 1091 (1936).

W_0 contains the rest energy and the kinetic energy of the emitted (absorbed) particle.

Table I.

W_0	1 5	2	3	4	5	6	7	10
$\zeta_1(W_0)$	0·1409	1 3062	12·185	41 416	97·652	189·05	324 36	1076 3
$\zeta_2(W_0)$	0 1826	1 0575	7·1836	20·104	40 190	67 392	101·95	248 74

Table 1 gives numerical values of ζ_1 and ζ_2 for W_0 lying between 1·5 and 10 mc^2, and Fig. 1 gives the common logarithm of these functions.



It is of some interest to notice that two experiments would be sufficient to test the above theory, since a single one is enough to determine the constant C:

$$C = \frac{\lambda\zeta_1 - 10^{-4} Z^3}{\lambda\zeta_2 + 10^{-4} Z^3},$$

the experiments being carried out for different values of W_0 and Z, and giving directly the corresponding values of the ratio $\lambda(W_0,Z)$. In the calculation of the ratio λ, the particular value $C = 0$ leads to the hypothesis of Fermi in which J_1 alone (put equal to unity) enters into the interaction term.

Intramolecular Folding of Proteins by Keto-Enol Interchange

IN recent communications[1] to this and other journals, the hypothesis has been developed of a lactam-lactim interchange (I) to account for the linear folding of polypeptide chains in keratin and myosin and what appears to be a similar, generalized, intramolecular folding in the 'globular' proteins. We wish to point out that in certain respects the argument is unchanged if, instead of a lactam-lactim, a keto-enol interchange (II) is postulated.

of the latter is shown on the indicator
experiments by a sharp rise of pressure
by oscillations, and also by the char-
allic knock. With weaker mixtures the
iod of the cold flame is longer, and
bustion of the mixture can take place
iation of a cold flame.

In spite of the relatively low initial speed of propagation of the flame front in the 125 per cent mixture, the time τ for complete combustion is less than that for other concentrations on account of detonation. Thus:

$$x = 100 \quad 110 \quad 115 \quad 125 \quad 143$$
$$\tau = 70 \quad 64 \quad 65 \quad 60 \quad 110$$

The chemical theory of detonation is therefore capable of explaining both maxima on the Curves 1 and 4 of Fig. 1, where the mean velocity is plotted as a function of the pentane concentration. The effect of adding 0·33 per cent and 0·67 per cent lead tetra-ethyl ($Pb(C_2H_5)_4$) is shown in Curves 2 and 3, from which it is clear that whilst this anti-knock is without influence on the velocity of normal burning, it narrows and finally eliminates the region of detonation, so that at a concentration of 0·67 per cent the normal curve $\bar{v} = f(x)$ is obtained with a maximum for x at 110 per cent. The addition of 4·46 per cent isoamylnitrite (Curve 5), on the other hand, increases the detonating tendency of weak mixtures without affecting the shape of the curve for richer mixtures. The detonation region widens still more when 8·3 per cent $C_5H_{11}ONO$ is added (Curve 6) and the curve then contains only one maximum for x at 115 per cent. According to the thermal theory of flame propagation, the maximum should lie at about 110–115 per cent when dissociation of the products is taken into account.

Since lead tetra-ethyl increases and nitrites decrease the induction period of hydrocarbon cold flames, these experiments lend further confirmation to the chemical theory of detonation in motors.

Rate of Growth of Totally Submerged *Cardium edule*

By good fortune, data on the growth of *Cardium edule* have now been collected covering four summers' growth.

This bivalve is usually found between tide-marks, but it occurs also below low-water mark in this and other localities. The material for the present study was taken from the bottom of a Marine Lake constructed near high-water mark at New Brighton and first filled with water in May 1933[1]. In that year, there occurred a fortuitous settlement of cockles which provided a segregated population of known age. The conditions in the lake are not normal for submerged marine animals in that the water is stagnant, except when renewed by those spring tides which rise hereabouts 28 ft. or more. Each year the lake has been emptied about February for inspection, when the bottom is exposed; collections of cockles have been made yearly, except in February 1934. Significant settlements of young occurred in 1933 and 1936, only rare representatives of other seasons having survived[1].

The growth of the 1933 spat in the second and third summers has already been given[1] and is shown in Fig. 1 at 2 and 3, and that for the fourth summer is now added from a sample of 286 specimens recovered in February 1937. This year, large samples of the 1936 spat were also obtainable, and the size distribution in 1,000 is given in Fig. 1 in millimetre groups at 1 to represent the 0-year class at the end of the first summer's growth. This class is not serial with the others given in Fig. 1, but is probably sufficiently similar to the 1933 spat at the end of the summer of 1933 to give the trend of the mean rate of growth, *RR*. The latter curve is drawn through the co-ordinates for mean size (length) for each year-group and age in summers. It is of characteristic type and shows that decrease in length with age is not markedly accelerated at an age of four summers. It is known that length at later ages falls off sharply, and it is hoped that adequate samples of the same material may be obtained in the future to give definite expression to this.

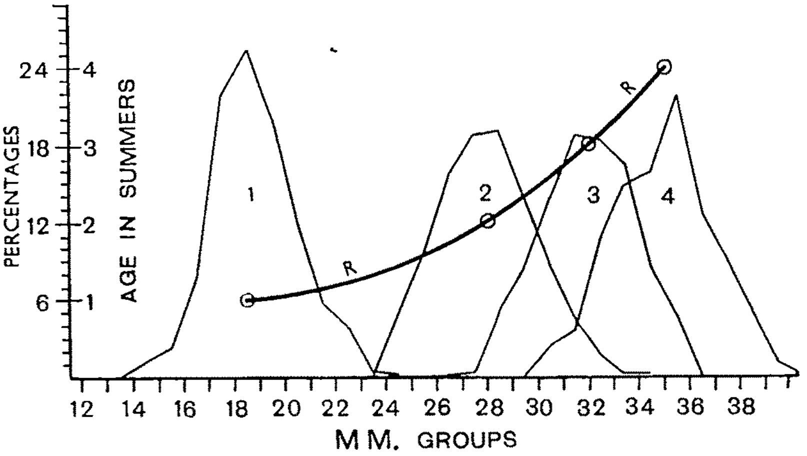

Fig. 1.

LENGTH-DISTRIBUTION IN MILLIMETRE GROUPS OF RANDOM SAMPLES (1, 2, 3 AND 4) OF *O. edulis* FOR, RESPECTIVELY, 1, 2, 3 AND 4 SUMMERS' GROWTH, COLLECTED IN NEW BRIGHTON MARINE LAKE; 1 AND 4 IN FEB. 1937, 2 IN FEB. 1935, 3 IN FEB. 1936. *RR* GIVES THE MEAN RATE OF GROWTH FOR ONE TO FOUR SUMMERS OF GROWTH.

Data for each summer group are as follows:

Age in summers	Year spatted	No. of individuals in sample	Range in size (length) in mm. groups	Approx. modal value in mm.	Approx. increment in modal value in mm.

The spat have been found to settle in this locality about the end of June, so that age in summers is not the same as age in calendar years.

There is a notable absence of very small spat in the 1936 brood, which was collected on a 1 mm. sieve. Possibly only the early spatfalls survived or, on the other hand, the late spat were eaten by crabs, fishes or other inhabitants of the lake. Although these bivalves have been under water constantly, their growth is less than that found on the shore in

Forty-four days after the inoculat
we observed small uredia on the up
several of the pustules. Further exami
that, in a total of 129 pustules, uredi
in 50, and that 21 of these contain
uredia and telia may occur on the
surface of a pustule, but more freq
upper surface.

The failure of pustules to produce æcia after intermixing of the nectar is not a new phenomenon. It has been observed from time to time in the F_2, F_3 and F_4 progeny of certain crosses, but uredia and telia were never before found associated with this condition.

The other culture that produced uredia and telia on barberry was obtained from a field collection made in 1934, and was identified as race 21. Sporidia from telia developed in the greenhouse in 1936 produced two types of pustules on barberry in about equal numbers. Pustules of the first type were normal in appearance and, on intermixing of the nectar, produced æcia. The pustules of the second type were almost white, with no pycnia, or only rudimentary ones that rarely produced pycniospores. Uredia were recently observed on five pustules of this type on a barberry plant inoculated 43 days previously. Two of these pustules also contained teliospores. Fig. 1 shows an infected barberry leaf bearing a compound pustule, one component of which contains æcia and the other small uredia.

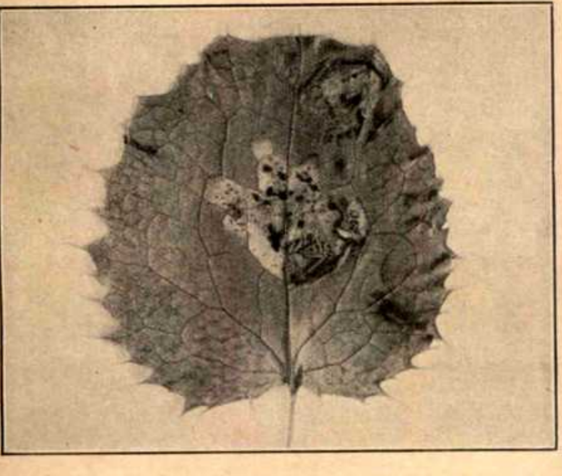

Fig. 1.

LOWER SURFACE OF A BARBERRY LEAF SHOWING A COMPOUND PUSTULE OF *Puccinia graminis Tritici* OF RACE 21. ONE COMPONENT OF THE PUSTULE CONTAINS AECIA, THE OTHER, SMALL UREDIA. (SLIGHTLY ENLARGED.)

The urediospores and teliospores produced on the barberry by both of these races are normal in appearance. The urediospores germinate normally and readily infect wheat seedlings, but are apparently unable to infect barberry leaves. The strains are therefore still heterœcious. The nuclear condition has not been investigated. A fuller report will appear later.

Flashing of Fireflies in Jamaica

DURING the past summer, the members of the Seventh Botanical Expedition of the Johns Hopkins University witnessed displays of firefly activity in the British West Indies as spectacular in their way as any reported from the Orient.

In front of the expedition's laboratory at Chestervale, in the Blue Mountains of Jamaica, there was a thatch palm which bore below its whorl of leaves an inflorescence a metre in diameter. For about a week in June, and again a month later, this inflorescence was transformed nightly into a sphere of seething flame by the flashes of thousands of fireflies which gathered there. Later, other displays were discovered, particularly on two large acacia trees overhanging the Clyde Valley which harboured such prodigious swarms of fireflies that the nebulous glow was visible half a mile away.

All the fireflies on these trees were of one species, *Photinus pallens*, and the females outnumbered the males in the ratio of 4 : 3. Each firefly flashed regularly about twice a second while walking along the twigs, and entirely independently of any other individual. There was no sign of synchronism or of response between any individuals or between different trees. The flashing was not inhibited by heavy rain, by lightning, or by the beam of a powerful flashlight, but did not occur on moonlight nights. It continued from about 8 p.m. until 3 a.m., and during dull days many of the fireflies remained in the trees all day.

Although these enormous aggregations were particularly brilliant on rainy nights, it is probable that they did not arise as a consequence of the fireflies taking shelter, because displays were also observed on clear nights. Likewise, although some individuals were seen apparently sucking juice from the fresh fruit scars on the palm tendrils, it is probable that food was not the specific cause of the aggregations, since the fireflies collected in several species of trees.

Photinus pallens is conspicuously positive to continuous illumination, and is the only Jamaican Lampyrid firefly which is frequently attracted indoors by lamplight. It was found that when the beam of a flashlight was directed into a bush or on to the grass, specimens of both sexes of *P. pallens* soon begin to fly from all directions, alight in the illuminated area, and flash regularly. Such nuclei, when they came to contain a dozen or so specimens, maintained themselves autonomously by the addition of new individuals from the surrounding area. Accordingly, it seems probable that this photo-positivity is the explanation of the huge swarms which gathered in the palm and acacia trees. Several individuals collected fortuitously in a small area would make sufficient illumination to serve as a focus for the addition of new recruits, like bees joining a swarm, and sufficient individuals remain on the tree during the day to insure its becoming a focus on the following night.

Whatever the cause of the aggregation, it serves an important function in bringing the sexes together for mating, and many coupling pairs were observed on the palm tendrils. The mating, however, appears to be due entirely to accidental contact of the sexes during their peregrinations on the branches. The aggregation habit thus seems to take the place of the accurate systems of flashing signals which serve to bring male and female together in some species of firefly.

I am greatly indebted to the late Prof. D. S. Johnson for laboratory facilities in Jamaica, and to the National Research Council of the U.S.A. for research funds.

Potassium Permanganate as an Aid to the Production of Asexual Fructifications by *Phytophthora erythroseptica* Pethybr.

WHEN small portions of pure cultures of *Phytophthora erythroseptica* are transferred to water, conidiophores and conidia (zoosporangia) usually develop from the mycelium after a few days, and this behaviour has been found to be stimulated by the addition of a little permanganate solution to the water. Young vigorously growing cultures do not react in this way.

To produce these results the following method is recommended. Portions of the medium (ground Quaker oats agar) in which the fungus has been under cultivation for 6–12 months are placed in drops of tap water on microscopic slides laid on white paper, and permanganate solution (0·01–0·02 per cent) added to the water, until a faint pink colour becomes just perceptible. Cover slips are put on the preparations, and the slides are then placed in Petri dishes lined top and bottom with moist blotting paper, and incubated at 16°–20° C. After 72 hours, sometimes sooner, the production of conidia begins, and their formation reaches its maximum in 84–96 hours. If too much of the reagent is added the medium and hyphæ stain brown, and fructifications may not occur until after 6–7 days. Cultures one month old will give conidia when treated in this way, but older cultures are preferable as germination of some of the oospores in the latter also occurs.

It may be pointed out that this method places this fungus in an exceptionally good position for teaching purposes, as the following facts may all be rapidly demonstrated with it:

(*a*) Inoculation of potato tubers with pure cultures produces typical pink rot in 8–10 days, and the parasite is easily recovered in pure culture from the rotted tubers.

(*b*) Sexual organs are freely produced in culture on ground Quaker oats agar in a comparatively short period.

(*c*) Using old cultures and treating with potassium permanganate as described above, the germination of the oospores, both by long hyphæ and by short ones ending in a conidium, may be observed, as recorded by Pethybridge[1]. In addition, the abundant production of sympodial conidiophores bearing conidia by the old hyphæ can be studied.

(*d*) When the formation of conidia is at its maximum, or abundant, and slides are removed from the incubator to the laboratory bench, germination of the conidia (zoosporangia) by zoospores takes place in about two hours.

I know of no other fungus of this type in which all these points can be studied so easily, and this makes it particularly useful for class work.

Specific Ionization by High-speed Particles

THEORETICAL calculation of the interaction between fast electrons and hydrogen atoms (Bethe, Williams[1], etc.) predict an increase of primary ionization when the energy of the incident particle exceeds about one million electron-volts. Wilson chamber experiments have not yet given quantitative results of sufficient precision to ascertain if that increase is real or not.

By a modification of our method[2,3], used for the determination of specific primary ionization of hydrogen by cosmic radiation, we have succeeded in measuring the variation of primary ionization of hydrogen by electrons of energy ranging from $0 \cdot 6 \times 10^6$ eV. up to that of cosmic rays. Contrary to theory, we find that the primary ionization *decreases* for high-energy particles.

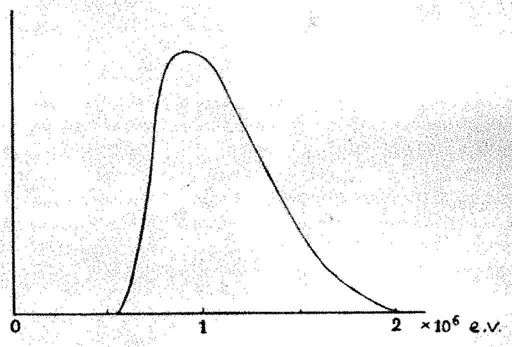

Fig. 1.

The electron source, used near the theoretical minimum ($v/c = 0 \cdot 97$), was a preparation of uranium-X_1 in equilibrium with uranium-X_2 (prepared by the method described by E. Stahel[4]); uranium-X_1 beta rays and secondary electrons were eliminated by means of a magnetic field. The result is a narrow beam of electrons of energy distribution shown in Fig. 1. The beam passes across the diameter of a hydrogen-filled Geiger-Müller counter (diameter about 2 cm.) through very thin walls ($0 \cdot 4$ mgm. cm.$^{-2}$); the slow secondaries emitted in the walls and on the edges of the last slit of the magnetic monochromator amount to less than 4 per cent of the primary rays.

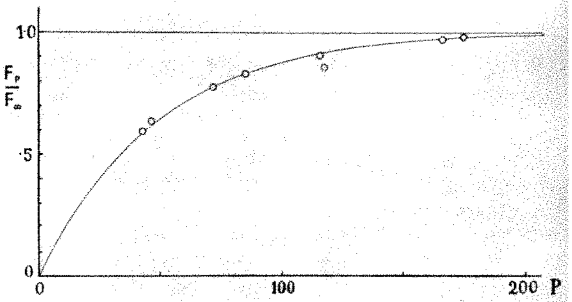

Fig. 2.

The frequency of counter impulses was measured for different pressures of hydrogen, ranging from 40 mm. to 180 mm. of mercury (N.T.P.). To eliminate the effect of residual counts (cosmic and gamma rays), which amount to about 15 per cent of the beta radiation, we automatically register that frequency every 30 minutes, with the shutter of the uranium-X source alternatively open and closed.

Fig. 2 gives an example of a series of measurements; the curve is the result of the calculation, taking the specific ionization as $7 \cdot 8$ cm.$^{-1}$.

The primary ionizations, computed from a series of such measurements, lie between $7 \cdot 5$ cm.$^{-1}$ and $8 \cdot 5$ cm.$^{-1}$. Although we hope to increase the precision of the method, it is already sufficient to show that the ionization near 10^6 eV. is definitely larger than at cosmic rays energy, where it is between 6·0 [2,3] and 6·2 [5].

A detailed account of this investigation will be published in the near future.

An incorrect reference and some ambiguity in a sentence of my previous letter[3] may have given a wrong idea of my opinion about the priority of the method used. I intended to say that Kolhorster's method[8,9] for measuring the *total* specific ionization was not convenient for the measurement of *primary* specific ionization; the principle of our method was suggested by L. Tuwim[6] and tested by us in 1934[7]. The method was applied to cosmic radiations independently by us (April 1936) and by Danforth and Ramsay (June 1936).

Note added in proof: A better series of measurements gives us a value of 8·2 cm.$^{-1}$ for 10^6 eV. energy.

Origin of Static Electricity on the Surface of Solid Dielectrics

INVESTIGATIONS, which I have carried out at intervals over the past twenty years, into the origin of the static electrical charges on the surface of cellulose during the manufacture and subsequent manipulation of paper, have shown a property—not peculiar to cellulose but shared by many other solid dielectrics—consideration of which may lead to a clearer conception of the origin of static charges by friction and contact.

When two plates of the same solid dielectric having identically similar surfaces are rubbed against each other, there is no sign of electrical charging by friction. I have found, however, that when two such surfaces of the same dielectric are pressed together into intimate contact, under a pressure of 100–120 lb. per square inch, and then separated, the two surfaces which have been in close contact are charged electrically, one positively and the other negatively. The potentials produced in this way are comparable in strength with those arising under the same conditions by pressure on plates of different dielectrics, although in the latter case the charges are much weaker than those produced by friction between the different dielectrics.

This development of an electric field in the boundary layer between two surfaces of the same dielectric pressed into intimate contact I have found to occur in solid dielectrics of such varying composition and molecular structure as ebonite, dry cellulose, dry gelatine and white mica. So far, it has not been found possible to predict which surface will become positively charged, and which negatively, or why, but I have observed that when fairly large surfaces electrified in this way are examined, it is sometimes found that one surface may show patches having a negative charge surrounded by areas having a positive charge, both corresponding to charges of opposite signs on the coincident areas of the second surface with which the first was in contact.

These phenomena cannot be explained in the light of the theories of Owen[1], Jones[2], Lenard[3] or Nernst[4], on the origin of frictional or contact electricity, but a possible explanation may be found in Freundlich's theory[5] of the production of charges by the rupture of surface adsorption layers.

The Dependence of the Thermal Expansion Coefficients of Silver Haloids on Temperature

EUCKEN and Dannohl[1] observed an increase of the expansion coefficients of the haloids of the alkali metals with temperature. Monocrystals of silver chloride and silver bromide also exhibit a peculiar increase of expansion at high temperatures (near the melting point) several times larger than those observed by Eucken and Dannöhl.

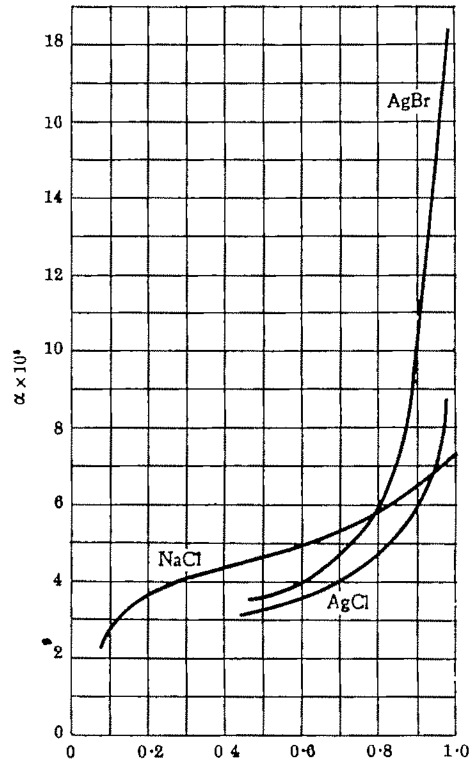

Fig. 1.

In Fig. 1 the expansion coefficients of sodium chloride, silver chloride and silver bromide are plotted as ordinates, while fractions of the absolute melting points T_s are plotted as abscissæ. The dependence increases sharply from sodium to silver and from chlorine to bromine, that is, the change is parallel to the increase of the deformation of the ions.

The character of the change of α with temperature for the group of haloids of potassium, sodium and lithium which crystallize in lattices of the same type is fairly similar. However, it appears from data already given by Eucken and Dannohl that the expansion of compounds which are more easily polarized shows a tendency to increase from 0·6 T_S.

The replacement of the alkali metals by the strongly deforming ion of silver causes the appearance of a large dependence of the expansion coefficient on the temperature, when with increase of the amplitude of the thermal motion the influence of the polarizing forces increases. Silver chloride appears to represent the limiting case, since silver iodide already crystallizes in a different type of lattice.

As a characteristic of the condition of the lattice of these compounds at high temperatures, it is of interest to recall the following jumps in the electrical conductivities at the melting point: sodium chloride, 3,000; silver chloride, 30; and silver bromide, 5.

The Low-temperature Transformation of Heavy Ammonium Chloride

AFTER having studied the low-temperature transformations of the ammonium halides, it was of interest to examine the influence of a substitution of the ordinary hydrogen in the ammonium group by heavy hydrogen. We started with ND_4Cl, obtained in the following way, working in evacuated apparatus. DCl prepared in a vacuum from D_2O (99·97 per cent) and phosphorus pentachloride, was after several distillations finally dissolved in D_2O. ND_3 prepared from D_2O and magnesium nitride (Mg_3N_2) and also several times distilled was dissolved in the DCl solution. This solution was evaporated in a stream of dry pure nitrogen, and then the solid ND_4Cl was dried in a vacuum desiccator over phosphorus pentoxide. No impurities could be detected in the ND_4Cl prepared in this way.

With ordinary ammonium chloride our statical dilatometrical investigations showed[1] at about − 30° a heterogeneous transformation, together with the phenomenon of heterogeneous hysteresis, within a temperature range of 0·3°. The result obtained with heavy ammonium chloride is quite different. The transition is a continuous one; the steepest part of the V,T curve appears in the neighbourhood of about − 24° and hysteresis has disappeared. This change in character of the transition is very remarkable. The shift of the transition to higher temperature was expected, but the change of a heterogeneous transformation into a homogeneous one was surprising, and the disappearance of the phenomenon of hysteresis, significant. In continuing our investigations with the other halides, we hope to reach a fuller understanding of the interesting phenomenon of hysteresis.

Magnetic Susceptibility of Mercury Vapour

I HAVE measured the susceptibility of mercury vapour by means of a method already described[1].

The atomic susceptibility of mercury has been found to be

$$\chi_a = -(78 \pm 7) \times 10^{-6}.$$

The susceptibility of the Hg++ ion had been measured several times by different investigators, and its most plausible experimental value[2] is

$$\chi_j = -40{\cdot}4 \times 10^{-6}.$$

Thus for the first time we are able to compare χ_a with χ_j and to compute the fraction of the diamagnetic susceptibility given by the two valence electrons of mercury:

$$\chi_e = \chi_a - \chi_j = -38 \times 10^{-6}.$$

We see that the diamagnetism of the two valence electrons of mercury is nearly equal to that of the ion. This result is rather important, because it suggests an explanation of the well-known fact that the diamagnetism of atoms is greatly influenced by the formation of molecules, as was observed, for example, in organic compounds by Pascal.

In the following table we give a comparison of the observed susceptibility of the mercury atom with that calculated by different approximate theoretical methods.

$\chi_a \times 10^6$.

Sommerfeld[3] calculated	Gombas[4] calculated	Slater[5] calculated	Experimental value
40·3	133·3	84·6	78

As may be seen from this table, the calculation carried out by Slater's method gives the most consistent results.

Phosphorescence of the Sea

WHEN sailing off the western Scottish coast, I found it possible to predict with certainty phosphorescent nights owing to a nipping sensation on the backs of my fingers after immersion in the sea. This seems to indicate some marine organism. As Dr. R. E. D. Clark's letter in NATURE of April 3 suggests, the phosphorescence is doubtless due "to the agitation of phosphorescent marine organisms".

If a boat-hook is pressed gently downwards into the water on a suitable occasion, there is little observable effect. The slightest jerk, however, that violently disturbs the water, at once produces luminosity but only in the disturbed region. During a very squally night when anchored in Mallaig Bay, I saw a beautiful display. The sea was black but the crest of every small wave that broke was brilliantly illuminated. May the streak effect be due, not so much to the accumulation of organisms in a particular region such as the meeting line of two currents, but rather to the agitation and consequent alarm of the organisms in the particular disturbed region ?

I once described in NATURE[1] the production of the characteristic luminosity so familiar at sea resulting from the sudden distortion of globules of certain viscous materials, and suggested that the organism displays its light—it may be voluntarily or otherwise—by a sudden muscular extension of cells containing such material.

Points from Foregoing Letters

EXPERIMENTS interpreted as evidence for the disintegration of the neutron have been described by Kikuchi, Aoki and Husimi, and the probability of the reaction has been calculated by them in terms of a collision cross-section varying from about 10^{-24} to about 10^{-25} sq. cm. C. W. Gilbert, C. L. Smith and J. H. Fremlin, by two different types of experiment, fail to confirm the disintegration of the neutron by bombardment with heavy hydrogen nuclei (deuterons). They consider that the cross-section for the disintegration of the neutron, if it takes place, is less than 3×10^{-26} sq. cm.

Prof. F. A. Paneth and Dr. C. Rosenblum state that the method of 'thermal precipitation' can be used for the separation, from the gas phase, of the active deposit of radium.

The ratio between the probability of absorption of a K-electron by a nucleus and the total probability of emission of a positron by the same nucleus has been calculated by Dr. A. Mercier on the assumption that the interaction term in the neutrino theory of β-radioactivity contains the five possible invariants to be obtained from Dirac matrices without introducing derivatives. Numerical values are given as functions of the maximum energy of particles emitted.

Drs. W. T. Astbury and D. M. Wrinch, while indicating the keto-enol interchange as an alternative mechanism to the lactam-lactim interchange recently proposed for the intramolecular folding of protein molecules, point out that the former offers a reason for folding in certain places only, given specific sequences of amino-acid residues, in that the hydrogen transference would take place at carbon atoms carrying side-chains.

A table giving the increase in pressure in pentane-air mixtures of various concentrations, at a series of very short time intervals after spark ignition, is submitted by A. V. Belov and Prof. M. B. Neumann. The initial rate of combustion passes through a maximum when the pentane concentration is 110 per cent. Graphs showing the mean velocity as a function of pentane concentration, and the influence of lead tetra-ethyl and of isoamylnitrite are given. The authors state that their experiments support the chemical theory of detonation in motors.

The size (length) distribution of cockles of one, two, three and four summers' growth, from the Marine Lake at New Brighton, has been determined by a group of investigators from the University of Liverpool. The trend of the mean rate of growth deduced from the graphs indicates that even at the age of four summers there is no marked decrease in the rate of growth.

The production of urediospores and teliospores of wheat stem rust (*Puccinia graminis Tritici*) on the common barberry (*Berberis vulgaris*) is reported by Drs. Margaret Newton and T. Johnson. These types of spores normally appear on the gramineous host only. They appeared in selfed cultures of two physiological races of this rust.

The swarming behaviour of fireflies of the species *Photinus pallens* in Jamaica is described by J. B. Buck. The fireflies gather in large numbers, apparently due to the fact that they are attracted by light, so that a few individuals collecting by chance serve, by their flashes, as a focus for the formation of a swarm.

R. McKay states that the addition of a small amount of potassium permanganate speeds up the formation of asexual fructifications (conidia) in the fungus *Phytophthora erythroseptica*. The conidia can thus be induced to develop within three to four days, which makes this fungus a useful material for class work.

Max G. E. Cosyns has measured the specific primary ionization of hydrogen by fast electrons of various energies. The results are in conflict with the theory, which predicts an increase of ionization for energy above one million volts.

Friction between similar surfaces of plates of the same dielectric, such as ebonite, does not give rise to electric charges, but J. Strachan states that when two such plates are pressed into intimate contact and separated, the contacted surfaces are found to be charged, one positively and the other negatively. It is suggested that this observation confirms Freundlich's theory for the origin of frictional and contact electricity by the rupture of surface adsorption layers.

The expansion coefficients of single crystals of sodium chloride, silver chloride and silver bromide have been plotted as a function of their melting-point temperatures by P. G. Strelkov, to show the abnormal increase near their melting points. The author points out that this behaviour is connected with the behaviour of the crystal lattice, as shown also by the jumps in electrical conductivities at the melting points.

Prof. A. Smits and G. J. Muller find that ammonium chloride containing heavy hydrogen in its molecule differs in its behaviour at low temperatures from the normal salt. The volume-temperature curve of the 'heavy' compound shows a homogeneous transition without hysteresis at – 24°, unlike the normal compound which shows a heterogeneous transformation with hysteresis at – 30°.

Research Items

Leg Muscles of Birds

IN a thorough study of the "Muscles of the Pelvic Appendage in Birds", George Elford Hudson has examined representatives of sixteen out of the twenty orders of North American birds (*American Midland Naturalist*, 18, 1; 1937). He has standardized so far as possible the terminology of the muscles with the recognized Basle Nomina Anatomica, and has introduced a method, new for bird anatomy, of illustrating cross-sections of the leg. The hind limb of a bird is worked by a full complement of forty-one muscles, and all these muscles are present in representatives of the order of game birds (Galliformes), suggesting a generalized and primitive condition. In the other orders examined, from one to nine muscles were missing from the full complement, and this indication of specialization was specially marked in *Colymbus* (eight missing), *Dryobates* (7), *Chaetura* (9), and the perching birds (8). On the other hand, *Cathartes* and *Zenaidura* had only one missing muscle. The leg musculature showed distinctive peculiarities for each major taxonomic group, and the author is of opinion that more weight ought to be placed upon the anatomy of soft parts in determining the systematic position and relationships of birds.

The Origin of Insects

IN his presidential address delivered before the Linnean Society of London on May 28, 1936, and published in the *Proceedings* of that Society (Part 4, December 1936), Dr. W. T. Calman discusses the above subject. It is maintained that the earliest insects were probably wingless forms not very different from the existing Thysanura. The idea of any relatively close affinity between insects and crustaceans meets with many obstacles. Some of the features which appear to link together the two groups are undoubtedly the result of convergent or parallel evolution. Furthermore, the fact that embryology has failed to produce any clear evidence of a head-segment, corresponding to that bearing the maxillulæ in Crustacea, discounts Hansen's belief that these organs are homologous with the so-called 'paraglossae' of the thysanuran *Machilis*. The discovery of Collembola from the Middle Devonian of Scotland led Tillyard to place these creatures at the very base of the insect series. The structure of the Collembola seems, however, to be of a specialized character suggesting that they are less primitive than the Thysanura. While it is claimed that the origin of insects is obscure, it is believed that the Symphyla reveal features that indicate what the immediate predecessors of the insects may have been like. An interesting problem raised in this address is the possibility that, in various groups of arthropods, there is a limit of size below which morphological differentiation is unable, as it were, to find adequate scope for expression. The number of segments in the appendages tends to be reduced, setæ are fewer and relatively larger in size, while the appendages themselves are less completely formed as compared with larger species. The primitive thysanuran *Campodea* and the Symphylan *Scolopendrella*, therefore, on these grounds are small enough to discount the absence or incomplete development of some features which would be expected to prevail in primitive forms. (See also NATURE of March 6, p. 399.)

Influence of Temperature Fluctuations on Animals

J. S. MIKULSKI (*Bull. internat. l'Acad. Polonaise*, 11, No. 5; 1936) reports the results of experiments on the influence of alternating temperatures upon the development of *Bufo americanus* and *Ambystoma tigrinum*. The experiments were carried out within the vital range of the animal and the rhythm of the changes of temperature were close to the natural ones. The acceleration in development at constant higher temperatures is offset by the fall in survival value and so they do not represent optimum conditions. Symmetrical alternating temperatures have a different influence as compared with that of constant temperatures in the two animals. The influence is shown by a change in velocity and a change in survival rate. *Ambystoma* exhibits a greater resistance to lower temperatures and the average resistance of *Bufo* is small in the extra-optimal range. The experiments show the necessity of observing the course of temperature fluctuations during the period of development.

Plants Poisonous to Stock

A VERY valuable account of American work upon plants poisonous to stock by J. F. Couch has recently been published (*J. Chem. Educ.*, 14, Jan. 1937). The annual losses of livestock in the United States are estimated to exceed two million dollars, and in Texas during one spring, animals valued at 300,000 dollars died from the effect of one species. It is pointed out that, though poisonous wild species are widespread in the pastures, well-fed animals are usually reasonably safe; when the ranges are over-stocked, the hungry animals turn to the less palatable species of plants, and then the damage is done. Among the poisonous types of plants described are larkspurs, lupins and senecios containing alkaloids; glucoside-containing plants in which the aglycone may be cyanogenetic or phenolic or in which the glucoside is a saponin; solanine-containing plants in which the solanine is at once both alkaloidal and solaninic—it is responsible for the occasional poisoning from sprouting potatoes; plants containing proteins antigenic like the bacterial toxins such as the ricin in the castor oil bean, and the resinoid-containing plants of the Ericaceæ. The chemical nature of these resinoid substances, which are difficult to crystallize, is little understood. It is very interesting to learn that the resinoid andromedotoxin is taken up by the bees from the flowers of some of these Ericaceous plants, and the honey then made may be very poisonous. Another obscure poison is the resinoid galitoxin found in the milkweed, *Asclepias galioides*. This makes this plant one of the most poisonous in the States, three ounces of the fresh plant being sufficient to cause the death of an adult sheep.

White Mould Disease of the Narcissus

THE fungus *Ramularia vallisumbrosæ* causes a white mould disease of narcissus plants, which is particularly severe in Devon and Cornwall. Greyish streaks appear on the leaves, and later bear masses of white, powdery spores. The streaks may occupy considerable areas of the leaves, which are thus unable to manufacture an adequate supply of food. Dr. P. H. Gregory has recently published an account of the disease and its control (*J. Minis. Agric.*, 43, No. 9, 865–69, December 1936). Spores are borne from February until May, and are readily distributed by wind and the splashing of rain, so that the disease can attain epidemic proportions in moist weather. Black sclerotia are formed by the fungus upon withered leaves in summer, and serve to perpetuate the disease. Control methods are mainly along the lines of general sanitation—the removal of leaves from infected plots, and appropriate rotation. There is no evidence that the fungus can contaminate the ground for more than one year, so that a rest of this duration will control the disease. The shoots of susceptible varieties of narcissi should also be sprayed with Bordeaux mixture, when the shoots are 3–6 in. high, in order to eradicate the sporing stage of the fungus. The waxy 'bloom' upon narcissus leaves makes it imperative that a suitable wetting agent be added to the spray fluid, in order that the greatest fungicidal action may be exerted.

Structure of Thin Metallic Films at Low Temperatures

THE properties of thin metallic films deposited at low temperatures are known to be anomalous. Such films possess high electrical resistance and poor optical reflecting powers. When the film is warmed there is an increase in conductivity, which Zahn and Kramer have reported to be discontinuous for films deposited by cathodic sputtering. They conclude that below a certain transition temperature characteristic for each metal, the film is amorphous. Tammann, on the other hand, believes that the difference in properties cannot be thus accounted for. G. Hass (*Naturwiss.*, 25, 232; 1937) describes electron diffraction experiments by which the structure of thin films of silver and antimony, deposited by condensation at low temperatures, has been determined. For silver, well-defined interference rings were obtained even at low temperatures (− 175°), which became sharper as the temperature was raised, thus indicating that the smaller crystals present at − 175° became larger with rise of temperature. This process of crystallization was more important with the thinner films (50 A. thick) than with the thicker ones (700 A.). For antimony, at low temperatures only two broad, diffuse rings were obtained, showing the predominance of a colloidal structure. At room temperature, however, the diagram indicates the existence of fairly large crystal units with thread structure. No transition temperature could be detected in either case, and the films were not amorphous at low temperatures.

Permonophosphoric Acid

ALTHOUGH permonophosphoric acid is a powerful oxidizing agent, converting manganous salts in the cold to permanganate, and is thus perhaps capable of useful application, its preparation by the interaction of phosphorus pentoxide and concentrated hydrogen peroxide is difficult. G. Toennies (*J. Amer. Chem. Soc.*, 59, 555; 1937) has found that the heterogeneous interaction between these two substances in acetonitrile as an inert solvent yields solutions of permonophosphoric acid which are relatively stable even at room temperature. In two experiments, 65·3 and 68·0 per cent of the phosphorus pentoxide were converted into the peracid by the reaction $P_2O_5 + 2H_2O_2 + H_2O = 2H_3PO_5$. The solution, even in the cold, gave the characteristic reaction with manganous salt. Some experiments on the rate of formation and of decomposition of the peracid and the stabilizing effect of low temperature (−12°) are recorded.

Metal Spraying

DEVELOPMENTS in metal spraying were considered by E. C. Rollason at the annual meeting of the Institute of Metals held in London on March 10–11. Twelve years have elapsed since the last paper on this subject was presented to the Institute of Metals. During the interval, radically new designs of apparatus have been evolved using powdered and molten metal as well as wire. Many new applications have been successfully exploited, some of which, such, for example, as in the building up of worn machinery, are becoming of great importance to the engineer. The author concludes that each of the three types of metal spraying equipment has its own characteristic advantages which will allow it to survive competition. Owing to its low costs, the powder process will, in the author's view, prove successful in spraying large surfaces with zinc, especially where the coat is afterwards to be painted. The powder spraying pistol also offers possibilities in connexion with the spraying of brittle metals and alloys of high melting point which cannot be drawn into wire. The molten metal instrument, on the other hand, can produce thick coatings of the lower melting point metals at a reasonable price, especially since the metal can be used in ingot form and neither acetylene nor oxygen is required. The wire pistol will, he believes, hold the field in building up thick deposits on worn articles as well as for producing heat resisting surfaces. Even in the production of zinc coats, the wire pistol offers important advantages in connexion with the spraying of internal surfaces, although the cost is higher than that of the other processes.

Meteor Heights from the Arizona Expedition

A NOTICE by Ernst Öpik of the results of this expedition, which deals in the first report with meteor heights and velocities, has appeared (*Proc. Nat. Acad. Sci.*, 22, 525; 1936). Out of 22,000 meteors recorded during the expedition, 3,540 were observed simultaneously from two stations separated by twenty-two miles. It was found that meteors meeting the earth were vaporized fifteen miles higher than those overtaking it, the higher kinetic energy being predominant in spite of the much less air-mass encountered. Sporadic meteors provided 80 per cent of the whole material, and only 7 per cent was contributed by the well-known major showers. The sporadic meteors were mostly extra-solar with high hyperbolic velocities, nevertheless their heights at the beginning and ending were nearly the same as those deduced for the solar meteors. The suggestion is made that this fact, which apparently contradicts the previous statement that the fast meteors were vaporized higher, can be explained by a difference in composition of the bodies. Solar-system meteors are mostly stone and sporadic meteors iron, and they would differ considerably in the time and heat required for vaporization. This explanation will scarcely satisfy everyone in spite of the fact that there appears to be some independent evidence of this difference in the composition of the meteors. Some light is thrown on the conditions prevailing in the upper atmosphere. One deduction is that a hydrogen atmosphere cannot exist below a height of about 130 km.

The First International Electrodeposition Conference

IN opening the first International Electrodeposition Conference, which was held at British Industries House, London, on March 3–4, Lord Melchett referred to the rapid advance which has been made in recent years in the science and practice of electroplating and other electrodeposition processes, and paid a tribute to the work of the Electrodepositors' Technical Society in furthering these developments and in organizing this first International Conference.

In the four sessions of the Conference, which were presided over by Mr. A. E. Ollard (president of the E.T.S.), Mr. C. Francis Carter, Mr. D. J. Macnaughtan and Mr. S. Field respectively, practically every aspect of electrodeposition was discussed. Four general papers by M. M. Ballay (France), Mr. E. J. Dobbs (Britain), Mr. G. B. Hogaboom (United States) and Dr. R. Springer (Germany) provided surveys of current practice and tendencies in the authors' respective countries. As would be expected in view of the present wide dissemination of ideas and information through the medium of scientific and technical publications, differences in practice between various countries are mainly those arising from differences in public taste and range of demand, or from differences in availability of certain materials. Thus, preference in Great Britain for cadmium plate with a matte surface has limited the use of baths for the direct production of bright cadmium deposits, which are largely operated abroad. Shortage of certain non-ferrous metals in Germany has led to the development of improved methods for electroplating on aluminium; to the more extensive use of anodized aluminium; to the use of insoluble anodes in nickel-plating baths, the composition of which is maintained by additions of nickel carbonate, or to the production of nickel anodes by electrodeposition from such baths on lead strip; and to the elaboration of methods for producing firmly adherent electrodeposits on articles of non-metallic composition such as bakelite and celluloid, which are so successful that they will undoubtedly retain their importance when normal supplies of metal become available.

Among special features of technique, particular reference was made to the 'copper degreasing process' employed mainly in France. M. A. Chabany (France) showed that this process, which consists of cathodic treatment of the basis metal in an alkaline cyanide solution containing copper, so that degreasing is accompanied by copper deposition, needs slight modification when applied to zinc surfaces. Loss of cyanide from the solution during operation is attributed to its oxidation to cyanate.

In the United States, Germany and Great Britain, rapid advances are being made in the development and utilization of 'automatic plant', in which articles of standard shapes and sizes are carried by means of conveyor chains through a succession of tanks in which preliminary cleaning operations, electrodeposition, and certain finishing processes are carried out, each for predetermined times. One automatic nickel-plating plant in Great Britain is using 12,000 amperes and turns out more than a million articles per week. Dr. J. Kronsbein (Britain) described a new type of automatic plant for nickel deposition in which the work bars are transferred from tank to tank by means of electromagnets, with arrangements for varying the time occupied in the transfer; and a novel chromium-plating plant in which the articles to be plated are held on the periphery of a magnetized double-disk wheel which revolves on a horizontal axis and thus carries the work through the plating solution. In Germany and the United States, electrolytic 'galvanizing' of wire is carried out on a large scale: sixty large plants in Germany consume about 300,000 amperes. Electrotinning of steel strip is practised in Germany, and is in course of commercial development in the United States.

The possibility of electrodepositing nickel and then chromium in a single automatic plant has been difficult to realize owing to the necessity for polishing the nickel undercoat before depositing chromium on it. Much attention has therefore been given to the direct deposition of 'bright nickel', and several types of plating bath for this purpose are now in operation. Dr. Schlotter's solution, which contains aromatic sulphonic acids, and baths with other organic addition agents are widely used, but several speakers stressed the value of the nickel-cobalt type of bath, which is claimed to give deposits equal in physical characteristics to an ordinary nickel deposit and to be the only bright nickel solution which can be completely controlled by chemical analysis. Methods for the production of bright deposits of several other metals are in use, and Dr. B. Egeberg and Mr. N. E. Promisel (United States) described the principles of a method which they are developing for evaluating the relative brightness of electrodeposits.

The introduction of simple and reliable tests for adhesion, porosity, thickness, and corrosion resistance of electrodeposits is making it possible to lay down specifications for plating to meet various conditions of service. Several contributors gave examples of such specifications which have been adopted by certain industries in their respective countries, and some speakers directed attention to the importance of specifying the minimum thickness required on 'significant surfaces' instead of or in addition to the average thickness over the whole article. Examples of the extent to which the thickness of silver plate may vary on various parts of the surface of articles of specified shapes were furnished in the survey of silver-plating practice presented by Mr. F. C. Mesle (United States).

Papers dealing with the development and practice of electrodeposition of particular metals were also furnished by Dr. G. Soderberg (United States) for cadmium from cyanide baths; by Mr. R. H. Atkinson (Britain) and by Messrs. E. C Davies and A. R. Powell (Britain) for platinum; by Mr. H. W. J. Pope (Britain) for gold; and by Dr. K. Schumpelt (United States) for the platinum metals—especially rhodium. Electrodeposited platinum and palladium are considerably harder than the corresponding rolled metals, and the hardness of electrodeposited platinum and rhodium is exceeded only by electrodeposited chromium. Owing to its exceptional resistance to attack by most chemical reagents and its fine white lustre, rhodium plating is applied not only to jewellery and as a non-tarnishing coating on silver ware, but also with considerable success to reflectors: it is unaffected by carbon particles sputtered from arc lights.

By means of a specially devised technique, Mr. A. W. Hothersall (Britain) showed that the adhesion of electro-deposits to nickel surfaces may be notably decreased by the presence of an invisible oxide film on the latter, and for securing the highest adhesion he recommended anodic etching of the nickel in sulphuric acid solution, the current being finally reversed for a moment. The special difficulty in securing adhesion of electrodeposits to chromium and its alloys is also due undoubtedly to the presence of an oxide film, and in order to overcome this Mr. G. E. Gardam (Britain) recommended cathodic treatment of the degreased surface in strongly acid nickel sulphate solution at high current density, which causes simultaneous removal of the film and deposition of nickel. It is advantageous to deposit a layer of copper (from the acid bath) on the resulting surface before plating with nickel from the regular nickel bath.

M. P. A. Jacquet (France) has established that whereas on a practically amorphous copper surface, produced by mechanical polishing, electrodeposition of copper begins from randomly distributed nuclei; a surface which has been electrolytically 'smoothed' by his method of anodic treatment in phosphoric acid retains its original crystal grain structure, and this structure is continued when copper is electrodeposited on it from the acid bath. In the initial stages of deposition, the deposit forms preferentially on grains which are favourably orientated with respect to the surface, and the character of its growth is affected by this orientation. Modifications of the phenomena observed when 'aged' baths are used are attributed to the presence of cuprous ions. The various modifications of the crystal structure of electrodeposits which may arise through inclusion in the deposit of substances added to the bath (addition agents) or of insoluble substances formed in the solution adjacent to the cathode surface, were shown in a remarkable series of photomicrographs presented by M. M. Cymboliste (France). Such inclusions are classified with reference to their character, origin and effect on the structure and properties of the electrodeposit; and the effects of varying the conditions of electrolysis are interpreted in terms of the influence of these conditions on the formation of inclusions. Prof. A. Phillips and Mr. W. R. Meyer (United States) reported results of an investigation of the upper limits of current density at which copper deposited from the acid bath on a copper surface ceased to continue the structure of the basis metal. From the cyanide bath no such continuation of structure was observed even at very low current densities. Even minute traces of lead in the acid copper bath were found to affect the character of the copper deposit, tending to make it dense, bright and somewhat brittle; but notable amounts of zinc in the bath scarcely affected the structure.

Papers by Dr. N. A. Isgarischev (U.S.S.R.) and by Prof. A. Glazunov (Czechoslovakia) and Dr. M. Schlötter (Germany) dealt with the mechanism of deposition of metals from complex salt solutions; and contributions from Prof. L. S. Ornstein in collaboration with B. Baars and P. J. Haringhuizen (Holland) were concerned with a comparison of the behaviour of electrodeposited and evaporated metallic films towards corrosive agencies, which had been investigated by means of a specially devised optical method.

Permanence of Oceanic Basins and Continental Masses[*]

IN his presidential address to the Geological Society of London in 1870, Huxley brought into correlation with geological science the scheme of zoological provinces which he had proposed to the Zoological Society two years before. He recognized the fact that the distribution of life, as then known, implied "a vast alteration of the physical geography of the globe", but he nevertheless conformed to the orthodox view of the time regarding the persistence of a general uniformity in the positions of the four great oceans from Devonian or perhaps earlier times.

That the oceanic basins and continental masses had, from the earliest geological times, occupied their positions, with little more than marginal changes, was an idea that originated in its geological bearing with J. D. Dana in 1856. Taken in conjunction with the then prevailing notion, developed by W. Hopkins, that the earth was solid to great depths, the doctrine of permanency persisted for many years unchallenged; it is still held by many geologists in an attenuated form.

After the publication of the "Origin of Species" in 1859, showing, in the words of Darwin, that "each species has proceeded from a single birthplace", the distribution of animals and plants became a critical test of the validity of the doctrine of permanency. Edward Forbes had challenged the idea, but Darwin considered that, when he wrote in 1859, we knew very little about the strange accidents by which living beings secured transport over oceanic barriers; and accordingly he, followed by Lyell in 1868, considered that Dana's views could not justifiably be put aside.

W. T. Blandford, however, speaking as president of the Geological Society, twenty years after Huxley, with far more extensive data at his command, demonstrated that the distribution of animals and plants could not be explained without the previous existence of land surfaces across regions now occupied by oceanic deeps. Although Blandford at that time confined himself to arguments based on biogeography, his previous work in India had led him independently to the same conclusion regarding the southern oceans. It was Blandford who discovered in 1856 the glacial beds at the base of the Gondwana system of 'continental' rocks in India. Later work in the southern continents led to similar discoveries, and ultimately established a correlation between India, Australia, Africa and South America.

So long ago as 1879, Blandford pointed out, in the official "Manual of the Geology of India", that the fossil plants and land animals of the Gondwana system in India were related so definitely to those on the southern continents that land connexions must have existed at certain times, if not continuously, between these areas across the positions now occupied by the

---

[*] Summary of the Huxley Memorial Lecture delivered by Sir Thomas Holland, K.C.S.I., F.R.S., on May 4.

Indian and South Atlantic Oceans. This was well before Eduard Suess gave the name Gondwanaland to the supposed pre-Tertiary southern continent.

Work by C. Schuchert published in 1932 on the distribution of Tertiary fossils confirmed the conclusions established by Blandford from living forms. Schuchert similarly required land communications over some of the present oceanic areas, but demanded relatively small land bridges, thinking, as he said, that it would be "easier to sink smaller continental-like masses than larger ones".

Another, wholly different, explanation for the distribution of life has been elaborated in the last twenty-seven years, mainly by the late Alfred Wegener, who maintained that an ancient continental mass, which he named Pangæa, existed in the South Atlantic and Antarctic region and broke up during the Mesozoic period; that fragments of it drifted away to form most of South America, South and Central Africa, Madagascar, India and Australasia, taking with them their records of geological activities during Palæozoic times. This theory is thus assumed to account for the glaciation of lands like India which are in the northern tropics, as well as continents which are still south of the equator; it explains, too, the correspondences between the Gondwana rocks of India and those on the southern continents.

Wegener's hypothesis, according to many geologists, is based on insufficient and often discordant data, whilst mathematicians assert that the mechanics involved in these horizontal movements of continental masses are quite impossible.

Following a suggestion made by R. H. Rastall in 1929, it is now urged that discussion of the purely theoretical implications of this hypothesis should await the accumulation of geological data by work on the lines undertaken by A. L. du Toit in comparing Africa and South America. Du Toit has demonstrated the remarkable duplication of geological features between these two areas, from Lower Palæozoic, age by age, to Upper Mesozoic times. He has also noticed that when the formations vary in the usual way laterally, the variation eastward in Africa and westward in South America is generally greater than that between the corresponding formations on the opposed present shores, although these are now separated by the width of the South Atlantic. Du Toit reasonably concludes that the agreements are too frequently concordant to be regarded as fortuitous, and that the only explanation which best fits the facts is the assumption that these two continents were at one time near one another if they were not actually confluent continental masses.

If it be true that these continental masses have moved horizontally in late geological times away from one another, there is no reason why others should not have done so too, in spite of the circumstance that no completely satisfactory explanation of the mechanics involved can be offered at present. Further work on the lines so ably undertaken by du Toit is now more necessary than mathematical criticism with insufficient quantitative data regarding the physical state of the earth's sub-crust under the continents and oceans.

Magnetic and Optical Properties of Crystals

UNDER this title, Prof. K. S. Krishnan of the Indian Association for the Cultivation of Science (Calcutta) delivered three lectures in the Cavendish Laboratory, Cambridge, on April 26, 29 and 30. In the first lecture he dealt with recent studies of the diamagnetic properties of single crystals, particularly aromatic compounds. The method of deriving the principal susceptibilities of aromatic molecules by combining magnetic measurements with crystal structure determination was described and also the way in which molecular orientation may be predicted on the basis of magnetic measurements alone. A summary of Pauling's method of calculating the principal susceptibilities of any aromatic molecule was given. The experimental method for measuring anisotropy in magnetic susceptibility was demonstrated and also the remarkable property of graphite crystals both as they occur naturally and after exposure to potassium vapour or to oxidizing agents.

The second lecture was devoted to the recent work on paramagnetic crystals. Prof. Krishnan's study of the magnetic properties of $CuSO_4.5H_2O$ has confirmed the predictions concerning the ionic environment made on the basis of theoretical studies and has afforded a remarkable correlation of the magnetic properties with the details of the crystal structure. The influence of the co-ordination on the magnetic anisotropy of the cobalt ion is shown by the comparison of the susceptibilities of $CoSO_4.K_2SO_4.6H_2O$ with those of $Cs_3[CoCl_4]Cl$. The former salt, in which the paramagnetic ion is six co-ordinated, is of great magnetic anisotropy, while the second salt, in which the cobalt is four co-ordinated, has a very small magnetic anisotropy. This result also confirms predictions made on the basis of other physical data. The study of very small magnetic anisotropy of certain manganese salts has made possible the prediction of the entropy of these substances at temperatures near to absolute zero—an important quantity in view of the use to which these salts are put in obtaining very low temperatures by adiabatic magnetization.

The third lecture dealt with the absorption and fluorescent spectra of certain aromatic compounds. Anthracene, naphthacene and chrysene have well-marked pleochroic characters. The absorption spectrum in the ultra-violet region has strong bands for rays vibrating in that principal plane which is most nearly parallel to the plane of the molecules, and weak bands for rays vibrating in that principal plane which is most nearly perpendicular to the planes of the molecules. Naphthacene is a common impurity in anthracene and chrysene, and even when only a few parts per million of the impurity are present a strong fluorescent spectrum is observed. This has the remarkable property of being strongly excited in one plane only, no matter what the relative orientation of the plane of vibration of the incident light. This plane, corresponding to the vibration of the strongly excited spectrum, is coincident with that principal plane which is most nearly parallel to the molecular planes. Some experiments on the photo dissociation of potassium nitrate in ultra-violet light were also described.

University Events

CAMBRIDGE.—The eighth course of Scott Lectures are being given by Prof. W. J. de Haas, of the Kamerlingh Onnes Laboratory, Leyden, in the Cavendish Laboratory at 4.30 p.m. on May 3, 5 and 7. The subject of the course is "Low Temperature Research".

It is recommended that two additional University demonstratorships be established in the Department of Anatomy from October 1.

Dr. H. H. Thomas is proposed as the representative of the University at the International Congress of the History of Science to be held in Prague on September 22–27.

LIVERPOOL.—Dr. Hugh Gordon, lecturer in botany, has been appointed to a lectureship in botany, University of Tasmania, as from June 30.

MANCHESTER.—The completion of the New Arts Library, which will be formally opened by Sir Walter H. Moberly on June 2, releases the whole of the Christie Library for the housing of scientific books.

The University has launched an appeal for £300,000 for development and a further annual income of £10,000. Among the proposed extensions are a new dental school and hospital, presented by Mr. Samuel Turner of Rochdale, and a new laboratory for the school of physico-chemical research directed by Prof. M. Polanyi, which at present is most inadequately housed.

The Rockefeller Foundation has made a grant of £5,000, to be spread over four years, in aid of the biochemical research work being carried out under the direction of Prof. I. M. Heilbron.

Mr. R. W. James, reader in experimental physics, has resigned his post on appointment to the chair of physics in the University of Capetown. Dr. D. Sheehan, lecturer in neuro-anatomy, has resigned on his appointment to the chair of anatomy in the College of Medicine, University of New York.

Among the appointments announced this year are: Dr. Samuel Tolansky to be lecturer in physics; Mr. W. S. Walker and Mr. W. G. Wainwright, to be demonstrators in chemical technology; and Mr. H. B. May, to be assistant lecturer in bacteriology.

OXFORD.—G. R. Girdlestone, New College, has been appointed Nuffield professor of orthopædic surgery while holding the post of clinical director of the Wingfield-Morris Orthopædic Hospital.

Prof. J. A. Gunn, Balliol College, has been appointed to become Nuffield professor of therapeutics, while holding the directorship of the Nuffield Institute for Medical Research, on his ceasing to be professor of pharmacology.

Dr. J. C. Moir has been appointed Nuffield professor of obstetrics and gynæcology as from October 1 next. This professorship carries with it a fellowship at Oriel College.

C. G. T. Morison, Christ Church, has been re-elected University reader in soil science for seven years from October 1 next.

The following have been elected or re-elected to University lectureships in their subjects, for five or three years, as from October 1 next: J. H. C. Whitehead (mathematics), R. L. Hall (economic science), Dr. D. A. Jackson (spectroscopy) and G. D. Amery (history and economics of agriculture).

Science News a Century Ago

The Royal Geographical Society

AT a meeting of the Royal Geographical Society held on May 8, 1837, William Richard Hamilton (1777–1859) the president-elect being in the chair, the Royal Premium for 1836 was presented to Captain R. FitzRoy for his work done while in command of H.M.S. *Beagle*. Addressing FitzRoy, Hamilton said, "one of the first of your discoveries laid open to the commercial and scientific world the harbour of Bahia Blanco, the only one upon the eastern coast of South America, in which a considerable number of line-of-battleships can be at anchor. On the same coast, in the face of numerous difficulties, you explored for the first time, the deep and rapid river of Santa Cruz. You surveyed, at your sole expense, the Falkland Islands. On the western side of South America, you have for the first time laid down the archipelago of islands lying to the south of Chiloe, called Chonos, in lat. 45° S. When your term of service was on the point of expiring, and you were about to proceed on your way home, your zeal for science prompted you to engage a vessel, at your own expense, for completing the survey of the coast of Peru as far as Guayaquil. In circumnavigating the globe, you have for the first time, carried a complete chronometric chain of measurement, by twenty-two chronometers—many of them your own property—from east to west around the globe. You have also enabled Mr. Darwin, the well-known naturalist, to add greatly to our knowledge of the history of those regions."

Darwin was present at the meeting, and in his reply to the chairman's speech, FitzRoy remarked: "Mr. Charles Darwin embarked in the *Beagle* in 1831 as a zealous volunteer in the cause of science. At his own expense, he passed five years aboard the *Beagle*, on travelling in those countries she visited. When it is considered that Mr. Darwin never ceased to be a martyr to sea-sickness, his perseverance may be appreciated. Of the value of his labours, I understand you have been made partially aware; and I believe I am quite correct in saying, that the best judges estimate those labours very highly."

Bulwer's Petrel in Britain

IT was on May 8, 1837, that the first specimen of Bulwer's petrel (*Procellaria bulweri*, Jardine) in the British Isles was picked up dead, on the banks of the River Ure near Tanfield, Yorkshire. Gould describes the record in Part 22 of his "Birds of Europe" and Yarrell on p. 664 of vol. 3 of his "History of British Birds". The specimen is preserved in the York Museum. An inhabitant of the temperate North Pacific and North Atlantic, plentiful off Madeira, the Canaries, Salvages, Sandwich Isles and Japanese isles, this petrel is sooty black all over, with a pointed tail, and reaches $10\frac{1}{2}$ inches in length. There are traces of grey on the throat and head, and brown margins to some of the wing feathers, the irides are deep brown, bill black, legs black and grey, male and female being similarly coloured. The call of the bird, heard at its nesting haunts at night, is a pleasant one, consisting of four high notes and a lower, prolonged one, in marked contrast to the harsh calls of the great shearwaters which also nest on their islands.

The Kingston Valves for Steamships

AT a meeting of the Society of Arts on May 10, 1837, a Gold Isis Medal was awarded to Mr. Ross for an improvement in the adjustment of the object glasses of compound microscopes of high magnifying powers, and the large silver medal was awarded to Mr. Kingston of Woolwich Dockyard, for a safety blow-off pipe for the boilers of marine steam-engines.

When steam was applied to ships, it was necessary to cut holes through the skin of the ship for admitting water to the condensers and for the purpose of blowing-down the boilers. The early plan was to fit a cast-iron pipe through the wooden planking and place a valve or cock on the inboard side. If this valve or cock became defective, it was difficult to repair with the ship afloat. John Kingston, a foreman at Woolwich, therefore devised a form of conical valve with a long spindle of very simple construction, having the great advantage that the pressure of water outside the ship tended to keep it on its seating.

Sir David Brewster on the Absorption of Light

ON May 11 and 25, 1837, a paper by Sir David Brewster was read to the Royal Society entitled "On the Connexion between the Phenomena of the Absorption of Light and the Colours of Thin-Plates". An abstract of the paper said: "The phenomena of the absorption of light by coloured media have been regarded by modern philosophers as inexplicable on the theory of the colours of thin plates, and therefore irreconcilable with the Newtonian hypothesis, that the colours of natural bodies are dependent on the same causes as the colour of thin plates. The discovery by Mr. Horner of a peculiar nacreous substance possessing remarkable optical properties, furnished him [Sir David] with the means of instituting a more accurate comparison between these two classes of phenomena. From the phenomena of thin plates, of polarized tints and of absorption, the existence of a new property of light is deduced, in virtue of which the reflecting force selects out of differently coloured rays of the same refrangibility, rays of a particular colour, allowing the others to pass into the transmitted ray, a principle not provided for in either of the theories of light to which the phenomena of absorption are ultimately referable."

J. A. F. Ozanam (1773–1837)

JEAN ANTOINE FRANÇOIS OZANAM, the eminent medical historian and epidemiologist, who died on May 12, 1837, of tetanus following an accident, was born on July 9, 1773, at Chalamont near Bourg-en-Bresse, the son of a notary. After studying philosophy at Lyons in 1790–91, he passed six years in the French army and took part in the campaign in Italy, where he was present at the most important battles. In 1797 he obtained with some difficulty his discharge from the army, and after an unsuccessful venture in business, took up medicine on the suggestion and encouragement of the celebrated surgeon Marc Antoine Petit. In December 1810, at the comparatively late age of thirty-seven years, he qualified at Milan, where he devoted his attention to the sick and wounded French and Italian soldiers taken prisoners by the Austrians. In 1816 he left Milan for Lyons.

Ozanam's chief work was a history of epidemic, contagious and epizootic diseases in Europe from the earliest times and especially the fourteenth century down to his own day. The first edition was published at Lyons in five volumes in 1817–23, and the second in four volumes at Paris in 1835.

Societies and Academies

London

Royal Society, April 29.

H. H. POOLE and W. R. G. ATKINS: The penetration into the sea of light of various wave-lengths measured by emission or rectifier photo-electric cells. Further measurements of submarine daylight, using emission cells, gave for the vertical extinction coefficient 20 miles from land, $\mu_v = 0{\cdot}11$ for blue and $0{\cdot}19$ for near ultra-violet. The light travelling upwards was about two per cent of that going downwards. Measurements were made with Weston selenium rectifier cells, corrected for the curvature of the illumination current relation, using a modified form of the Campbell Freeth zero-resistance circuit. Infra-red is eliminated in less than 2 m. Red is reduced to 1 per cent at 10 m. The deeper water, 35–50 m., was clearer than that near the surface in the English Channel 10 miles from land. Near the shore the difference between red and green is lessened, but blue is relatively more heavily absorbed and differs more from green.

A. KEYS, B. H. C. MATTHEWS, W. H. FORBES, R. A. MCFARLAND and D. B. DILL: Individual variations in ability to acclimatize to high altitudes. The International High Altitude Expedition made observations at sea-level, 9,000, 12,000, 16,000 and 20,000 ft., of the physiological constitution of ten normal subjects. The capability of acclimatization of the members of the party was graded by a questionnaire as to the deviation in physical and mental performance from their sea-level values, of all members of the party. By this classification, the members of the party were arranged in order at each altitude. A number of physiological properties were observed at sea-level and at each station. No one of these yielded a good correlation with the classification referred to above, but the whole series taken together with suitable empirical coefficients yield a good correlation with the acclimatization classification.

G. A. MILLIKAN: Experiments on muscle hæmoglobin *in vivo*; the instantaneous measurement of muscle metabolism. A photo-electric arrangement is described by means of which the degree of oxygen saturation of the naturally occurring intracellular muscle hæmoglobin in a cat's soleus muscle may be measured instantaneously and recorded continuously. This instrument provides both a chemically specific and time-sensitive method of measuring muscle metabolism, and neither the nerve supply nor the blood supply need be disturbed. Muscle hæmoglobin acts as a short-time oxygen store, helping to tide the muscle over from one contraction to the next. When the muscle contracts, its oxygen demand rises to its maximum value in less than $0{\cdot}2$ sec. from the onset of contraction. There is good general agreement between both resting and active oxygen consumption as measured photo-electrically in the muscle fibre, and in metabolic experiments of the usual kind made on repetitively contracting mammalian skeletal muscle. Resting value: $0{\cdot}07$ mm.^{3} O_2 per gm. per sec During tetanic contraction: $1{\cdot}0$ - $3{\cdot}5$ mm.^{3} O_2 per gm. per sec. Blood flow appears not to be greatly affected in the first few seconds of tetanic contraction These results are in agreement with those of Rein and Kramer, and differ from those of Anrep.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, May 10

UNIVERSITY OF CAMBRIDGE, at 5.—Prof. A. V. Hill, F.R.S.: "The Heat-Production of Muscle and Nerve: A Critical Survey" (Linacre Lecture).

ROYAL GEOGRAPHICAL SOCIETY, at 5.—Dr. C. B. Warren: "Medical and Physiological Aspects of the Mount Everest Expeditions".

UNIVERSITY OF LONDON ANIMAL WELFARE SOCIETY, at 5.30—(at University College, London).—Dr. N. K. Adam, F.R.S.: "The Destruction of Sea-Birds by Oil Waste".*

Tuesday, May 11

INSTITUTION OF CIVIL ENGINEERS, at 6.—Annual General Meeting.

Thursday, May 13

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (ROYAL SCHOOL OF MINES), at 5.30.—J. Henderson Smith: "Virus Diseases of Plants" (succeeding lectures on May 20 and 27).*

Friday, May 14

ROYAL ASTRONOMICAL SOCIETY, at 5.—Prof. N. E. Nörlund: "Astronomical Longitude and Azimuth Determinations" (George Darwin Lecture).

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

DEMONSTRATOR IN CHEMISTRY in the Woolwich Polytechnic, London, S E.18—The Secretary (May 13).

ASSISTANT (grade III) at the Aeroplane and Armament Experimental Establishment, Martlesham Heath—The Secretary, Air Ministry, S.2.D (Room 405), Adastral House, Kingsway, W.C.2 (May 14).

ASSISTANT (grade III) in the External Ballistics Department of the Ordnance Committee, Woolwich—The Secretary, Ordnance Committee, Royal Arsenal, Woolwich, S.E.18 (May 14).

LECTURER IN GEOGRAPHY in the Darlington Training College—The Principal (May 14).

LECTURER IN GEOGRAPHY in Bingley Training College—The Education Officer, County Hall, Wakefield, Yorks (May 15).

RESEARCH PHYSICIST for the Printing and Allied Trades Research Association—The Director of Research, 10 Robin Hood Court, London, E.C.4 (May 17).

RESEARCH OFFICER at the Ministry's Veterinary Laboratory, New Haw, Weybridge—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1 (May 17).

ASSISTANT in the Department of Mathematics in University College, Dundee—The Secretary (May 28).

ASSISTANT LECTURER IN BOTANY in the University of Birmingham—The Secretary (May 29).

LECTURER IN GEOGRAPHY in the College of St. Mark and St. John, Chelsea, S.W.10—The Principal.

LECTURER IN MECHANICAL ENGINEERING in the County Technical College, Worksop—The Principal.

The National Food Supply

IT will be a source of gratification to those who believe that the problem of the nutrition of their populations is worthy of serious consideration by responsible Governments, to be reminded that in Great Britain the Ministry of Health and the Scottish Office are instigating searching inquiries into the food supply of the nation as a whole and into the distribution of specially desirable foods among different sections of the community. Two years ago, these Government Departments appointed an Advisory Committee on Nutrition which included some senior civil servants from various Ministries and Departments, and some prominent scientific workers in the field of nutrition such as Prof. E. P. Cathcart, of the University of Glasgow, Sir Frederick Gowland Hopkins, of the University of Cambridge, Prof. E. Mellanby, secretary of the Medical Research Council, and Sir John Orr, director of the Rowett Research Institution, Aberdeen. Its terms of reference were: "to inquire into the facts, quantitative and qualitative, in relation to the diet of the people, and to report as to any changes therein which appear desirable in the light of modern advances in the knowledge of nutrition".

The Committee has now issued its first report*. It has had before it estimates of the total food consumed in recent years by the population of the United Kingdom, and was thus able to compare the quantities of food available with the nutritional requirements suggested in the report by the Technical Commission of the League of Nations Health Organisation, which is reprinted as an appendix to the present report. This comparison does not pretend to give an exact picture of the existing state of affairs; nevertheless its results are of considerable interest. It is calculated that the national food supply, after allowing a margin of 10 per cent for wastage, contains more than sufficient calories to meet the energy requirements of the population on the basis of the report of the League Commission. It is the opinion of the Advisory Committee, therefore, that all except a small fraction of the population are getting as many calories as they require. There is no deficiency of fat in the national food supply, though there is some deficiency in the diet of the very poorest. The total amount of protein available for the population is sufficient to supply its needs, but seeing that the proportion of animal protein in the diet increases as the standard of living rises with income, it is considered probable that there is some shortage of animal protein in the diets of the poorest section of the community.

The greatest discrepancy between the estimates of national consumption and the recommendations of the League Commission relates to liquid milk. The requirements on the basis of the League Commission's report are estimated to be equivalent to an allowance of seven-eighths of a pint daily per head of the population, whereas the present actual consumption in the United Kingdom is less than half this amount. Even if the consumption of condensed and dried milk is taken into account, the total quantity works out at only 60 per cent of the Commission's recommendation.

This deficiency is regarded with special concern and is referred to again and again in the present report. The Advisory Committee published in 1936 a memorandum on the nutritive value of milk which is republished as an appendix to this report. In it the opinion is expressed that the desirable amount of milk for children is from one to two pints a day, for expectant and nursing mothers about two pints a day and for other adult members of the community half a pint. The Committee deplores the fact that there is a deficiency of milk in the diet of large sections of the population at a time when there is a substantial surplus of liquid milk produced in the United Kingdom. The hope is expressed that the State will endeavour to ensure that a sufficient supply of safe milk will in the future be brought within the purchasing power of the poorest. It is considered that there is no other single measure which would do more to improve the health, development and resistance to disease of the rising generation than a largely increased consumption of safe milk by mothers, children and adolescents. While whole milk is a more complete food than other dairy products, the Committee would like to see skimmed milk and buttermilk more readily available for human consumption than they are at present.

---

* Ministry of Health. Advisory Committee on Nutrition. First Report. Pp. 52. (London: H.M. Stationery Office, 1937.) 1s. 0d. net.

With regard to other foods specially recommended by the League Commission, it has been possible in one or two instances to make comparisons between its recommendations and the actual consumption in the United Kingdom. The present average consumption of eggs is estimated to be 2·9 per head per week, while it is calculated that 3·9 per head per week would be necessary to satisfy the Commission's recommendation. The average weekly consumption of potatoes is in the region of 56 ounces per head; the Committee would like to see a larger consumption, to replace some of the sugar and highly milled cereal of the diet. It is pointed out that while sugar may be a useful source of energy, it possesses no other food value and, when taken in large amounts, it dulls the appetite for more valuable foods and may thus have an unfavourable effect on nutrition.

The recommendations which the Advisory Committee have made are based on experimental and medical data, which have already indicated the importance of good nutrition for the maintenance of health. It is admitted, however, that a great deal more information is necessary before a final verdict can be passed on the effect of good diets on the health of a community. The Committee has already proposed and instigated additional inquiries which should enable further practical suggestions to be made for improving the nutrition of the masses. It wishes, for example, to obtain a more reliable estimate than has hitherto been possible of the distribution of the population in income groups; it has invited Government Departments to undertake dietary surveys on a comprehensive scale and has recommended specifically that exact studies of the diets of several hundred families should be carried out in England, Scotland and Wales; it has also recorded its view that efforts should be continued to establish a reliable group of tests for the assessment of the state of nutrition of individual human beings.

Viscount Astor directed attention in the House of Lords on May 5 to the Advisory Committee's report, and obtained a statement given on behalf of the Government by Viscount Gage. Lord Gage said that the Government accepted the conclusions of the Committee, but thought that much more information is desirable; and the Government is prepared to collect it. A threefold inquiry is proposed. The Ministry of Labour will make an inquiry in connexion with the cost of living index figure. For this it is hoped to secure the weekly budgets of 10,000 families taken over four separate weeks in various parts of Great Britain. These results will be checked by another inquiry, called a qualitative dietary survey, of a much more detailed character. This is already in progress, and will eventually embrace 500 families, of which 200 may be from Scotland. Then, from the last census figures, a definite proportion, say, one in 500 or one in 1,000, of the family census schedules will be taken. Those are expected to show, roughly, after certain allowances are made for altered conditions, the distribution of the population according to occupation. These statistics will be compared with the information in the possession of the Ministry of Labour with regard to the wage rates current in such occupations. It is hoped that the statisticians will be able, on this basis, to correlate the results of these various inquiries and present a working analysis of how the incomes of the various classes of the community are divided with special reference to food.

What is not clear at the present moment is whether the Government only accepts the conclusions that the diet of the country is improving and that more data about this should be obtained, in which case a political gesture has been made to get over an embarrassing situation; or whether the main conclusions and recommendations have been accepted. If the Government has accepted these and intends to carry them out, then the new science of nutrition is about to be applied for the welfare of the people, and we are on the eve of what will be the greatest social reform of this century.

The Ice Age in Detail

The Quaternary Ice Age
By W. B. Wright. Second edition. Pp. xxv + 478 + 23 plates. (London: Macmillan and Co., Ltd., 1937.) 25*s*. net.

WHEN the first edition of the "Quaternary Ice Age" was published in 1914, it took its place at once as the standard English text-book on the subject Since then our ideas concerning the Glacial Period have undergone a profound change, for the monoglacial theory, after a comparatively brief tenure, has had to give place to the older view of successive ice-advances, alternating with milder, or even warm, interglacial episodes. A new and revised edition of this well-known book has, therefore, been looked forward to for some long time.

To review all the evidence that brought about such a change in ideas was indeed a formidable task, for mere revision of a text-book published in 1914 would obviously be inadequate. Nothing less than a largely rewritten edition would meet the case; and on the whole the author has accomplished this difficult task in an admirable manner. Of the 24 chapters of the second edition, only a few are reprinted in their original form; most have been expanded and brought up to date, and some are new. A considerable increase in size of the volume is the result; many new illustrations and the useful bibliographies now added to each chapter will be a great help to students.

The general chapters on glaciers and ice sheets, glacial deposits, theories of the Ice Age, the mammals of the time and earth movements during and since the Glacial Period remain much as in the earlier edition, but there are minor revisions. More attention has been given to the phenomena of glacial retreat, so clearly demonstrable in north-western Europe, and to the wind-borne loess, now believed to be intimately connected with the phenomena of ice-advance. But much rewriting has been necessary, because we now realize the inevitable effects on the contemporary fauna and lora of successive glaciations and interglacial phases—particularly as they affected the history of early man. As a result of this realization, geology and prehistoric archæology have become overlapped to such an extent that the glacialist, o be on safe ground, must be well versed in the study of prehistoric man, if not actually a specialist in that branch. A large mass of literature had, herefore, to be summarized in the preparation of this new edition, and the author has succeeded fairly well in his brave attempt.

The treatment of the details of the geology and archæology of the east of England gives the impression of being insecure and rather below the high standard of the rest of the work. A strange omission is that of the story of events in the valley of the Lower Thames (although a new chapter has been added on the river gravels of the south of England) from the deposits of which we have recently gained our most substantial knowledge of human occupation in relation to late glacial history (*vide* W. B. R. King and K. P. Oakley's useful summary and J. P. T. Burchell's work). Also, a few pages might have been spared for a review of the remarkable disturbances of soft strata, which, although they have given rise to much speculation and argument, have thrown valuable light on glacier-motion and the behaviour of englacial and subglacial material. These omissions, however, are but slight blemishes in a work which, taken as a whole, is a masterly summary of existing knowledge in a subject admittedly of wide range and crowded with detail. Mention only can be made, for example, of admirable chapters on the older and newer drifts of the British Isles, the glaciation of northern Europe, the Alps, and North America, and on raised beaches and submerged forests.

At the end of the volume are accounts of the author's isokinetic theory of oscillations of sea-level and of the post-glacial changes of climate in Europe. As the author regarded this theory as his most original contribution in the first edition of the book, it is perhaps only fair to quote his own words in the second edition: "...the demonstration that isostatic movement alone", that is, the reaction of the earth-crust to loading by and unloading from the ice-masses, "was an inadequate explanation of the quaternary oscillations of shore-line, but that it became completely adequate when coupled with eustatic change of ocean-level due to the return of the water bound up in the ice-sheets. This theory, which was then [in 1914] quite novel, has received ample confirmation from recent researches, and, being now completely established, is given the name Isokinetic, from the fact that shore-lines are cut when the two motions are equal and in the same sense".

A word of appreciation is due to the publishers for the obvious care taken in producing this handsome volume.

An Advance in Kantian Scholarship

Kant's Metaphysic of Experience:
a Commentary on the First Half of the "Kritik der reinen Vernunft". By Prof. H. J. Paton. (Library of Philosophy.) Vol. 1. Pp. 585. Vol. 2. Pp. 510. (London: George Allen and Unwin, Ltd., 1936.) 2 vols., 30*s*. net.

EVER since the philosophy of Immanuel Kant was given to the world, in the years 1781–90, there seems to have been a tacit understanding among his readers and commentators that this philosophy would not do as it stood; and thus there has grown up a curious but almost universal custom of reading Kant not for the sake of what he said, but for the sake of what the reader presumes that he ought to have meant. Idealist philosophers, including even the German neo-Kantians after Cohen, have rejected as 'dead' all elements in his philosophy except those which became a basis for the work of his idealist successors, and the first large-scale commentary on Kant that was produced in Great Britain was informed by the same assumption. More recent scholars have claimed to discover, with the aid of textual criticism, that the "Critique of Pure Reason" is a patchwork of fragments, written at different dates within a period of eleven years, embodying widely different and even contradictory views, and at last hastily assembled in the space of three months. On this view, Kant has no consistent philosophy of his own; his greatness rests merely upon the enormous width of his interests and the illuminating nature of many of his suggestions, but he involves himself in far more difficulties than he elucidates.

Prof. Paton's book represents the long-overdue reaction against these cavalier methods. Starting with the fact that the "Critique of Pure Reason", whatever its materials may have been, was obviously planned and executed as a whole, he examines and expounds in detail the text of the first two sections of it, the "Aesthetic" and the "Analytic", and discovers that it embodies a continuous and close-knit argument resting on certain assumptions which, whether true or not, are at any rate coherent, reasonable, and in no way idealistic. In these respects Prof. Paton's interpretation has the considerable merit of crediting Kant with having done very much what Kant himself always said he had done.

Two points in the author's interpretation of Kant call for special mention. The first is concerned with the doctrine of the thing in itself. To the scientific world, Kant has been known chiefly by what he has in common with Comte and Spencer. The sphere of possible knowledge, he says, is confined within the limits of experience, and the world which we know in experience is merely phenomenal. Behind the phenomenon lies the thing in itself, but that is and must always remain unknown. It is true that Kant also held doctrines of an absolute time and an absolute Euclidian space, and certain opinions about the nature of mathematical thinking, which have got him into trouble with mathematicians and physicists; but these are details, and the essence of his doctrine lies in distinguishing between phenomena and the thing in itself, and confining all possible knowledge to phenomena. Against this the philosophers have argued that, if the thing in itself is really unknown, Kant cannot even know that it exists, and is inconsistent in claiming to do so; that in the long run he is actually driven to admit that he is not certain of its existence, and that he ought to have denied it altogether and become a true idealist.

Prof Paton shows in the work under notice that these criticisms are beside the mark. When Kant denies that we can know the thing in itself, he does not deny that we can form an idea of it as being something in general; what he denies is that we can have insight (*einsehen*) into its nature. Nor does he ever entertain a doubt of its existence; the passages which have been held to express such a doubt have been misinterpreted. Kant thinks it is quite certain that, behind the phenomena of Nature, there is something the existence of which we can recognize in a general sense, but the character of which we cannot conceive. This doctrine may be erroneous, but it is neither inconsistent nor *prima facie* unreasonable. That it is really Kant's doctrine was established by Adickes, to whose praise Prof. Paton consecrates a footnote; it has also been recognized by Dr. Ewing in his "Idealism", and it may be hoped that the recognition may become general.

The other point which requires special mention is Prof. Paton's treatment of Kant's doctrine of the schematism of the categories. The doctrine has been generally ignored, or treated as a piece of pedantry; but in fact it is indispensable to the coherence of Kant's argument. If the scientific worker, whose presuppositions Kant claims to be elucidating, is to recognize in Kant's categories his own working principles, which are simply the minimum assumptions necessary in order to make sense of a world in space and time, then Kant himself must take explicit account of space and time, and see to it that any more abstract principles of his own, which he may be able to extract from an analysis of pure logical forms, shall be given a spatio-temporal form, that is, 'schematized', before he can set them forth as valid for scientific thought. Prof. Paton's understanding of this, and his demonstration that Kant also understood it, constitute not the least of the merits of this book.

Kant's philosophy does not lend itself to quick study and epigrammatic judgment; but those who are prepared to study it seriously and in detail, as it demands, will do well to take Prof. Paton as their guide. His commentary is indispensable to those who wish to obtain a clear and balanced view of the fundamental principles of one of the greatest philosophies of modern times.

Comparative Biochemistry

An Introduction to Comparative Biochemistry By Dr. Ernest Baldwin. Pp. xviii+112. (Cambridge: At the University Press, 1937.) 5*s*. net.

UNTIL recently, the criteria of zoological and botanical relationships were, in the main, qualities of external or internal structure, or of functional behaviour. The possibly more intimate and certainly less obvious resemblances and differences between different animal types, in the chemical make-up of their tissues and body fluids and in their metabolic habits, have only recently begun to come within the sphere of established knowledge. It is as a direct result of the new methods which have been developed in biochemistry, particularly as an outcome of increased accuracy in dealing analytically with very small quantities of material, that information has accumulated in the last few years regarding these matters, throwing a flood of light on the ways in which the physical and chemical problems presented to different types of living organisms at various stages in their evolutionary history have been overcome.

In this book an outline of recent advances in this relatively untrodden field—an outline that is never far from the available experimental findings—is presented in an admirably succinct way by Dr. Baldwin. Beginning with a consideration of the osmotic difficulties of sea- and fresh-water fauna and how these are met, the author proceeds to the devices used by land animals for conservation of water, and the biological significance of the different ways in which nitrogen is excreted in different groups of land and sea animals, particularly in relationship to the ornithine cycle and purine metabolism. A section is devoted to the strange distribution of the two phosphagens. Recent work on the biochemistry of the supply of oxygen to the tissues in relation to respiratory pigments is summarized, and is followed by a brief descriptive account of some pyrrol, indol and carotene pigments. This last chapter on pigments seems a trifle abrupt, and less well woven than the earlier chapters into the general evolutionary story.

It is doubtful whether the word uræmia (p. 32 *et seq.*), normally used clinically to describe a definitely pathological condition which may occur irrespective of the level of urea in the blood, is the wisest one to use to describe a physiological condition in which there is a high content of urea in the blood and tissues. It is not quite clear why, if urea were produced in the cleidoic egg, it should disturb osmotic relationships (p. 47), since, apart from the wall of the urinary bladder and the gills of elasmobranchs, most tissues seem to be freely permeable to this substance. It would have been interesting to have had the author's views on the relationship of the recent findings of W. L. Davies, that trimethylamine oxide occurs in appreciable quantities in the urine and milk of dairy cows after they have eaten various beet by-products, with the statement (in the section beginning on p. 43) that it is only in the excreta of marine teleosts that this substance occurs. Does the normal diet of these animals contain large quantities of betaine or related compounds? Is the occurrence of trimethylamine oxide in the excreta more a reflection of the type of compound in the ingesta than of any fundamental metabolic peculiarity?

In case there is virtue in the fact that the reviewer read through this book from cover to cover with the greatest pleasure in a single sitting, let it be put on record. Dr. Baldwin's book may be confidently recommended as a delightfully yet firmly written introduction to this infant science. Sir Frederick Hopkins contributes a characteristic foreword.

H. D. K.

A Modern Climatology

Handbuch der Klimatologie
Herausgegeben von W. Koppen und R. Geiger. In 5 Bänden. (1) Band 1, Teil B: Die klimatologischen Elemente und ihre Abhangigkeit von terrestrischen Einflüssen, von Prof. Dr. V. Conrad; Band 1, Teil C: Das geographische Systeme der Klimate, von Prof. Dr. A. Köppen; Band 1: Titel, Vorwort, Inhalt, alphabetisches Sachregister. Pp. x + xii + B556 + C44 + 12. 90 gold marks.

(2) Band 2, Teil J: The Climates of North America. Part 1: Mexico, United States, Alaska. By Prof. Robert DeC. Ward and Prof. Charles F. Brooks. Pp. x + 326. 60 gold marks.
(Berlin: Gebrüder Borntraeger, 1936).

(1) The encyclopædic handbook of climatology by Köppen and Geiger makes a considerable advance by the issue of two new volumes. The first of these, containing vol. 1, Section B and Section C, is a volume of about 600 pages. In Section B Prof. V. Conrad, of Vienna, gives an outline of the climatological elements and their dependence on terrestrial influences. He has taken a wide view of the domain of climatology, and we might perhaps regard much of the matter which he has included as falling rather within the domain of physics of the atmosphere. In view of the thoroughness of the treatment we have no cause to regret the author's choice of topics. In five sections he treats in turn solar and terrestrial radiation, the constitution of the atmosphere and its impurities, the measurement and representation of temperature, wind and air flow, and the hydrometeors. We find throughout the whole book careful discussion of methods of observation and of methods of representation of the observations. Thus the question of how best to obtain a reasonable mean temperature for the day from observations at standard times is considered with some care. The influence of the location and aspect of the observing station on the meteorological conditions is stressed, particularly with regard to temperature and rainfall.

For almost every meteorological element we find tables, charts or diagrams, showing the distribution over the globe, the variation with height, or the diurnal or annual variation. Data from many parts of the world are shown in the text or diagrams. The mean winds of the globe are described, and an outline of the scheme suggested by V. Bjerknes for the general circulation of the atmosphere is added. Special local winds, land and sea breezes, and hill and valley winds are described. The longest section is that dealing with the water vapour in the atmosphere. All aspects of the subject are mentioned. Evaporation is discussed with reference to the theories which have been put forward in such overwhelming numbers. But here the reviewer noted that the work of O. G. Sutton, which he would regard as one of the most valuable of all recent contributions to this most difficult subject, receives no mention. Some idea of the thoroughness with which the author has done his work may be gathered, however, from the fact that he has even succeeded in collecting some data relating to the diurnal variation of rainfall, a subject which few writers have cared to embark upon. References to original papers are plentiful, and form one of the most useful features of the book.

In Section C, Köppen gives in about forty pages an account of the well-known classification bearing his name, which is based on considerations of temperature and rainfall. Köppen distinguishes eleven main types of climate, but there is obviously an almost infinite gradation of possible subdivisions. Fig. 4 shows the annual distribution of temperature and rainfall in each of the main types, and in view of the importance of this diagram it is regrettable that it is on so small a scale. The short account is, however, a useful summary of the bases of Köppen's classification of climates.

The whole volume is one of the most useful additions to the list of reference books of the working meteorologist. It is naturally a severely technical work, and cannot be regarded as light reading by even the most technically minded. But it will have its place in every library of meteorological books.

(2) The second of the two new volumes, vol. 2, Section J, describes the climates of Mexico, the United States and Alaska. Much of the work of collecting and discussing the observations was done under the partial guidance of the late R. de Courcy Ward. He shared with Prof. C. F. Brooks and Mr. A. J. Connor the duties of author, but many American meteorologists contributed to the work of compiling the book. It begins with a general introductory description of the physical features of North America and their bearing on the climates of the continent. We are here reminded that the fact that the continent narrows southward instead of northward has the consequence that, instead of a Sahara, North America has the Gulf of Mexico.

The volume is in three sections, dealing respectively with Mexico, the United States and Alaska. Each of the three sections ends with a series of tables, giving for a large selection of stations monthly and annual means of temperature, pressure, wind directions, relative humidity, days with snow, hail, thunderstorms, strong wind, or fog, to name but a selection of the contents. The text discusses these observations, charts and diagrams being freely used where desirable. Most of the charts cover the whole of the continent, including Canada, though the climatology of Canada is to form the subject of the next volume, which is due to appear shortly. The authors have carried out their difficult task with care and good judgment. Of particular interest are the chapters in the section on Mexico dealing with climate and vegetation, and climate and population, and in the section on the United States dealing with climate and health and climate and crops. The volume will be valuable to all who are interested in the meteorology, climatology, or economics of the North American continent.

The general editors of this monumental climatology, Köppen and Geiger, are to be congratulated on the way in which the work not only progresses, but also maintains the high standard which marked its early stages. One cannot help a feeling of envy of the American colleagues, who will have an excellent and up-to-date climatology of their country at their elbows, while wondering why no one has yet seen fit to produce an equally complete modern climatology of the British Isles.

D. B.

Analytical Chemistry

Textbook of Quantitative Inorganic Analysis
By Prof. I. M. Kolthoff and Dr. E. B. Sandell.
Pp xv+749. (New York: The Macmillan Co., 1936.) 20*s*. net.

IN this work, the production of well-known teachers and investigators of analytical subjects, we have one of the best productions on the subject of quantitative inorganic analysis available to students. It sets out from the position that analytical chemistry is a fundamental branch of the science, a statement which the reviewer accepts fully.

The presentation of the subject is such that many who have passed beyond the stage of the advanced student and have reached the heights of research will find it profitable to read the volume. The theory of *p*H values, solubility product and the electroanalytical process is given sufficiently fully for practical purposes. A chapter on errors in analysis will repay careful study, and we may recommend in particular that part of the chapter dealing with significant figures obtained in the course of an analysis. The section on volumetric analysis is introduced by a very useful discussion of the theory of the various branches of this class of analytical operations. It includes a fairly full account of potentiometric titrations, and of various types of indicators, many of which, for example, erioglaucine *A* and phenanthroline, are here given the attention they deserve.

A short section of the book is devoted to physicochemical methods, and that part which deals with colorimetry and spectrophotometry should prove valuable to all who have to use colorimeters in their work. The use of so-called unspecific properties (density, refractive index, etc.) for the analysis of mixtures is dealt with rather too briefly, as is indeed the rest of the chapter, which gives an outline of some other physico-chemical properties useful in investigation. While the methods here described for the analysis of brass and steel are useful and practical, it is a matter of opinion whether the space devoted to these matters might not possibly have been better utilized for fuller discussion of some of the physicochemical methods. We agree that the description of the analysis of silicate rocks is valuable to the student because of its wide and general application, but the description of the examination of these two alloys seems to the reviewer somewhat restricted for a work which is so philosophic in its general outlook.

The subject matter is well arranged and has adequate references to original papers and special works on analysis, while the descriptions of the more important gravimetric and volumetric processes are sufficient. For teaching purposes, three different sizes of type have been employed, and this, together with the problems set at the end of the chapters, will be found particularly advantageous in using the book.

This work can be recommended with confidence as providing the foundations of a sound training in theoretical and practical quantitative analytical chemistry. We have not discovered any errors, and misprints, if any, must be very few indeed. We agree heartily with the views on the scope and purpose of the study of analytical chemistry propounded in the preface. J. J. F.

Laboratory Manual for Chemical and Bacterial Analysis of Water and Sewage

By Prof. Frank R. Theroux, Edward F. Eldridge and Prof. W. LeRoy Mallman. Second edition, revised and enlarged. Pp. x+228. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 15*s*.

THIS book is essentially a utilitarian product, greatly appreciated as proved by two editions appearing within nineteen months: the added bacteriological section further enhances its value.

The first part is chemical, subdivided into three sections, water, sewage and polluted water; these arbitrary divisions cause some duplication. The instructions are efficient, concise, well arranged and furnished with calculated examples from selected data. This part describes the preparation of the necessary solutions and reagents and concludes with chemical notes on analytical methods. Here the preparation of the caustic soda solution seems wasteful, while the diluting water for the B.O.D. (biological oxygen demand) misses the point by aeration after adding alkali.

Part 2 gives an efficient account of the bacteriological examination of water and sewage; also the composition of the required media; these follow on the lines of the American Public Health Association methods—hence *B. Welchii* is omitted. The number of media enumerated is excellent. However, the absence of Noble's official cyanide citrate medium for the Coli-ærogenes group is noted. The colon index method is used for routine comparative purposes; the Phelps and M.P.N. (most probable number) methods are given.

Calculations with numerous illustrative examples are prominent throughout. Unfortunately, small errors occur; p. 118, the atomic weight of iodine is a unit larger than usual; the equation is unbalanced; p. 119, the alkali equivalent is 0·1 per cent too high.

The organic determinations are, by a strange irony, the least satisfactory part of our present methods, due to unrealized errors and artefacts. The shepherding care here devoted to the nitric nitrogen in the Kjeldahl process deserves emulation even in more pretentious works; it would confer inestimable benefits upon all concerned and is fundamentally necessary to progress. J. W. HAIGH JOHNSON.

Die Tsetsefliegen:

ihre Erkennungsmerkmale, Lebensweise und Bekämpfung; ein Leitfaden für die Praxis. Von Dr. F. Zumpt. Pp. iv+149+15 plates. (Jena: Gustav Fischer, 1936.) 9 gold marks.

DR. F. ZUMPT, of the Institute of Tropical Diseases at Hamburg, has provided in the above work a concise and up-to-date manual on the tsetse flies. Within the compass of about 140 pages he has described the essential features of their structure, taxonomy, habits and the means for attempting their control.

The first section is devoted to general features of their morphology: this is followed by a short account of their methods of feeding and of reproduction. A longer section is given to taxonomy, wherein the characters employed for determining the various species are dealt with, together with accounts of their habits and geographical distribution. A short general statement of tsetse ecology follows, together with a more detailed discussion of ecological methods of study. The concluding part is concerned with the problem of combating these insects, both by purely local methods, such as trapping, and by the more comprehensive schemes of destroying or altering their natural environment. At the end of the work is a very complete bibliography (up to 1936) comprising about 400 references to separate publications.

While this manual gives a good presentation of the subject as a whole, its most useful part will probably be found in the account of the taxonomy and specific characters of these insects. A. D. I.

Forest Insects:

a Textbook for the Use of Students in Forest Schools, Colleges and Universities, and for Forest Workers. By Prof. R. W. Doane, Prof. E. C. Van Dyke, Prof. W. J. Chamberlin and H. E. Burke. (American Forestry Series.) Pp. xii+463. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 25*s*.

THE realization of the national importance of forestry, which has overtaken the North American continent in recent years, has manifested itself in various ways. Forest protection and reafforestation, in particular, have come to the front. Under the term protection come not only the combating of forest fires but also of the many biological enemies of living trees. Among these latter, insects are the most important.

Practical people in forests and parks, as well as teachers and students in academic institutions, need properly documented information to which they can refer. The present book aims at filling requirements of this kind. In its first four chapters general principles are dealt with in a brief and elementary fashion. Nearly seven eighths of the book are given to accounts of forest insects themselves. The essential information about each species is provided, while the bibliographies at the ends of the chapters guide the reader to sources giving fuller details.

The book is well arranged and clearly illustrated, and should admirably fulfil its purpose as a manual for North American use.

Méthode des caractéristiques pour l'intégration des équations aux dérivées partielles linéaires hyperboliques

Par Mlle. Hélène Freda. (Mémorial des Sciences mathématiques, Fasc. 84.) Pp. vii+82. (Paris: Gauthier-Villars, 1937.) 15 francs.

WITH great skill and clarity, Mlle. Freda has presented an account of the origin, development and applications of one of the most powerful methods of mathematical analysis. Starting with Cauchy's problem and Riemann's original method, she traces the extensions due to Picard, Volterra, d'Adhémar, Tedone, Coulon and Hadamard, with modifications and additions due to herself. There are references to mechanical and physical applications, and to the history of the subject. Prof. V. Volterra contributes an appreciative preface. H. T. H. P.

Water-Power in the United States

By Dr. Brysson Cunningham

II

Grand Coulee Dam

THE second of the great power projects in the United States to be described is the Columbia Basin Project, Washington. It includes the construction of a dam which, when completed, will be the second highest in the world; the formation of an artificial reservoir with an area of 82,000 acres or 128 square miles; the installation of a power plant which will ultimately exceed the capacity of any other now in existence, and an important irrigation canal system over adjacent territory.

The Columbia River, rising in the Canadian Rockies and crossing into the State of Washington near its north-east corner, has the greatest run-off but one in the country. It flows for 750 miles through the State into the Pacific Ocean, falling 1,300 ft. in its course, and is the largest river in the United States in point of potential power susceptible of economic development. It is obviously, therefore, a very suitable subject for exploitation in the interests of industry and agriculture.

The impounding dam is at the mouth of the Grand Coulee (Fig. 1), a natural basin formed by an earlier diversion of the river channel, probably during the glacial epoch, about 22 miles north of Almira and 92 miles by road west of Spokane. The work of dam construction was commenced in December 1933, and is expected to be completed by the end of the current year. As originally designed, the height of the dam was fixed at 300 ft., with a crest length of 3,400 ft., which would have erved for a power development of 520,000 horse-ower. It was the intention thereafter to supermpose a high dam upon this low dam, when funds became available for a combined irrigation and power development scheme. Constructional difficulties, however, arose from slides in the canyon walls above the site, and a consideration of the objectionable bonding of two structures, with the uneconomical accommodation for hydraulic machinery to cope with low-head and high-head conditions, led to the substitution, at the outset, of a dam of the concrete straight-gravity type, rising about 550 ft. above the lowest point of the foundation bed and capable of raising the river-water surface-level by 355 ft. This dam,

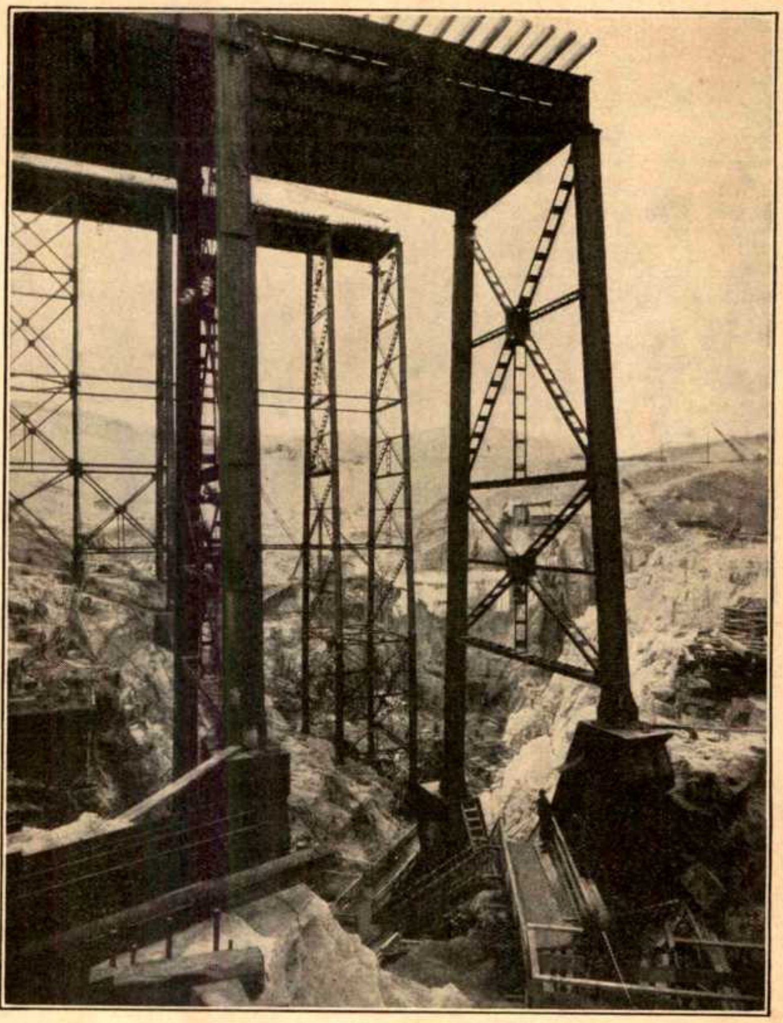

Fig. 1.

View of excavation in progress (December 1936) at Grand Coulee installation. The concreting of the dam just commenced.

superimposed on the natural granite, will have a crest length of about 4,200 ft., with a 1,650 ft. overflow spillway in the river channel portion, affording a flow capacity of a million cusecs. The structure is of enormous size, containing, with the powerhouse and other appurtenant works, no less than 11,250,000 cubic yards of concrete masonry, weighing more than twenty million tons—roughly, three times the volume and weight of the Boulder Dam.

The reservoir formed by the dam will extend for a distance of 151 miles from the Grand Coulee to the Canadian border, and up the Spokane River for 32 miles. The width averages a little more than 4,000 ft. The Columbia River, it may be added, is five times as large as the Colorado River, on which the Boulder Dam is located. The volume of water to be impounded in the Columbia River reservoir is sufficient to supply nearly 2,000 gallons for every inhabitant on the earth. In contrast with the Colorado River, the Columbia River water is practically free from silt.

The installed capacity of the Grand Coulee power plant will be 2,700,000 horse-power—half as much again as that of the Boulder Dam plant and six times as much as that of Niagara Falls. The continuous power output will be 1,240,000 horse-power. There are to be two power houses, one on each side of the dam, containing eighteen 150,000 horse-power vertical hydraulic turbine and eighteen main generating units of 120,000 kVA. capacity each, 60 cycles. There will also be three 7,500 kVA. service units. Water will reach the turbines through eighteen penstock culverts, 18 ft. in diameter, and the machines will operate under an average head of 335 ft. (maximum 360 ft.; minimum 265 ft.). It is expected that the plant will be ready to commence partial operation in 1942.

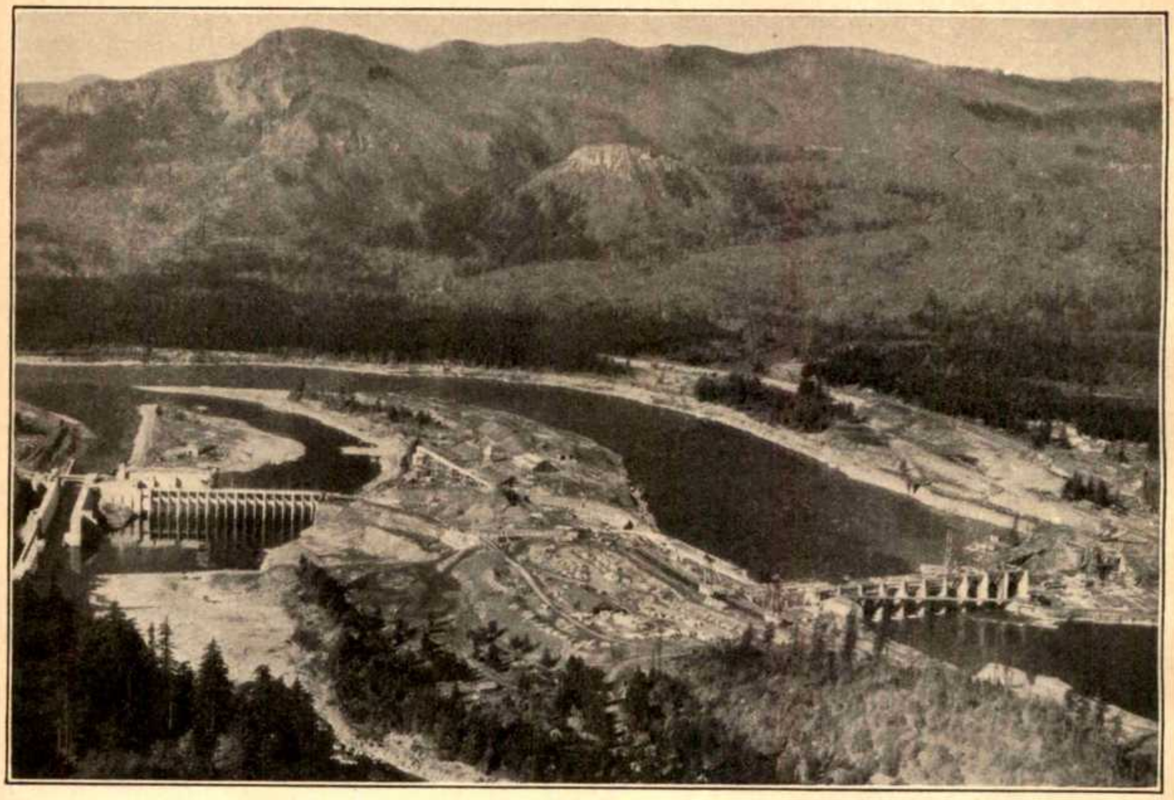

Fig. 2.

GENERAL VIEW OF THE BONNEVILLE INSTALLATION; UPSTREAM SIDE OF POWER HOUSE AND LOCK, WITH SITE OF MAIN DAM.

The reservoir is to be provided with an installation of twelve pumps, of 1,600 cusecs capacity each, driven by a 65,000 horse-power motor against a normal head of 295 ft., discharging through 13 ft. diameter outlets, about 700 ft. long, in a canal which leads to the reservoir.

The flow of the Columbia River is on an average 109,000 cusecs. The greatest recorded maximum is 492,000 cusecs, but it is believed that a peak of 725,000 cusecs was reached at Grand Coulee during the flood of 1894. The minimum discharge, after completion of the dam and the introduction of regulation, will be about 35,000 cusecs.

Irrigation is possible over an area of about 1,200,000 acres in the Columbia Basin, of which 980,000 acres will be by gravity and the remainder by supplemental pumping. The district lies on the east side of the Columbia River, between Soap Lake on the north and Pasco at the extreme southern end, with a maximum width of 60 miles. The land has been declared to be "the best undeveloped irrigation area on the continent".

The estimated ultimate cost of the entire undertaking is 377,000,000 dollars (£75,400,000) of which 179 million dollars is assignable to the dam and power plant and the balance to the irrigation system. The initial development at the Grand Coulee Dam is estimated to cost 60 million dollars.

II

BONNEVILLE DAM

The Columbia River furnishes other sites than the foregoing for the economical exploitation of water-power, including Rock Island and Bonneville. The former of these has already been developed by private enterprise ; the development of the latter, Bonneville, is now in hand by the U. S. War Department Corps of Engineers under an authorization of Congress on August 30, 1935. The main features of the Bonneville undertaking are a dam, a power house, a ship lock and fishways. The total cost, inclusive of an initial installation of two (out of ten) power units of 60,000 horsepower each, will amount to 45 million dollars (£9,000,000).

The Bonneville site (Fig. 2) is about 143 miles from the coast of the Pacific and the river is tidal for that distance. At this point, the river flows in a westerly direction in two channels, separated by Bradford Island. The dam is being constructed in the north or main, channel, while the power house and navigation lock are located on the south channel. The bedrock under the principal structures is a sedimentary deposit of volcanic ash, largely intermixed with pebbles and rock fragments of all sizes, and is locally known as Eagle Creek formation. There is a mushroom-shaped intrusion of andesitic lava of high quality which forms the foundation for the lock and the power house.

The dam is a concrete gravity structure at the base, supporting reinforced concrete piers for eighteen vertical lift steel gates. The gate openings are each 50 ft. wide and the piers 10 ft. thick, making the length of the dam proper, 1,090 ft. The width at the base is 200 ft. and the height above lowest foundation, about 170 ft. A service roadway is to be carried across the piers, so that the completed dam will have the appearance of a concrete multiple-arch bridge. The dam is designed to pass a flood of 1,600,000 cusecs—37 per cent in excess of the volume of the flood of 1894.

The ultimate capacity of the power installation will be ten 43,200 kw. units, 3 phase, 60 cycles, and one 4,000 kw. station service unit. Each of the main turbines will be of 60,000 horse-power, with a head of 45 ft. and a flow of about 2,200 cusecs.

The ship lock is designed to receive ocean-going vessels, so that by deepening the channel below Bonneville (the natural depth of which at low water ranges from 7 ft. to 50 ft.) such vessels may ascend from Vancouver to The Dalles, about 50 miles above Bonneville. The lock will have clear dimensions of 76 ft. in width by 500 ft. in length, and a depth of 24 ft. over the lower sills at low water.

The information on which the foregoing article is based has been supplied by the Bureau of Reclamation, Department of the Interior, Washington, so far as the Grand Coulee installation is concerned, and by the Corps of Engineers, U. S. Army, Washington, in relation to the Bonneville project, to both of which bodies, acknowledgments are also made for the photographic illustrations.

Medical Research in 1936

IN addition to the usual summary of the present position of many aspects of medical research, the report of the Medical Research Council[*] discloses that steps have been taken during the past year to develop the Council's policy of establishing senior clinical posts for whole-time work in research and higher teaching, such as will give a satisfactory career in later life to young men who devote themselves to the scientific study of clinical problems. The Council already supports, in whole or in part, three clinical research units in London, at University College Hospital, Guy's Hospital and the National Hospital for Diseases of the Nervous System. Reference is made to the establishment of a department of clinical research at Cambridge, under the regius professor of physic, in which research students are supported by the Elmore Fund, and to Lord Nuffield's gift to the University of Oxford for the development of research and post-graduate teaching in medical science.

---

[*] Committee of the Privy Council for Medical Research. Report of the Medical Research Council for the Year 1935–1936. (Cmd. 5378.) Pp. 172 (London : H.M. Stationery Office, 1937.) 3s. net

The Council has given special attention to another aspect of the problem, namely, the training of young clinicians with academic and research appointments in view: for this purpose it has instituted six post-graduate studentships and four research fellowships in clinical science and experimental pathology. The students receive a grant for personal maintenance while undertaking approved courses of study in Great Britain, which may include modern languages as well as advanced physiological, pathological and special clinical work under recognized teachers. The fellowships are for candidates who have already had some experience in the use of research methods, and are intended as probationary appointments for research in clinical science and experimental pathology under suitable direction in Great Britain.

The Council has also always considered problems of health and disease in relation to tropical conditions within its sphere: in fact, one of the chief reasons why it was originally placed under the direction of the Privy Council was that it should be free from territorial limitations. With the prospects becoming more favourable of being able to institute a wider programme of work in the tropics, the Council has appointed a Tropical Medical Research Committee, which contains representatives of the Colonial Office and of the Liverpool and London Schools of Tropical Medicine. The Committee having advised that the most effective means open to the Council of promoting investigations in this subject is the establishment of a small staff of highly qualified workers giving their whole time to research under the best possible conditions, the Council has awarded two junior and two senior fellowships with the view of training suitable candidates in research in tropical medicine. The Council's further intention is to establish, as suitable investigators become available under this scheme, permanent and pensionable appointments for research work in tropical medicine including senior posts: members of this staff will work partly in the tropics and partly in institutions at home. The terms of service will be as favourable as those applying to other Government appointments for men of similar professional standing.

There have been three changes in the constitution of the Council during the year: the Marquess of Linlithgow, Prof. E. D. Adrian and Mr. W. S. Morrison have retired and been succeeded by Lord Balfour of Burleigh, who becomes the new chairman of the Council, Prof. J. Mellanby and Mr. R. K. Law. Reference is made in the report to the award of the Nobel Prize in Medicine for 1936 to Sir Henry Dale, conjointly with Prof. O. Loewi of Graz, in recognition of their work on the nature of the chemical mechanism involved in the transmission of nerve impulses, and to the loss suffered by the National Institute for Medical Research by the death of Captain S. R. Douglas: Sir Patrick Laidlaw has been appointed to succeed Captain Douglas as deputy director of the Institute and head of the Department of Experimental Pathology and Bacteriology.

The scientific researches carried out by members of the scientific staff of the Council and by other workers supported by grants-in-aid cover the whole field of medical research: it is possible to refer to only a few of the more outstanding advances during the past year in this review.

Investigations have been continued on the properties of different viruses: in the case of influenza, it has been shown that the virus obtained in various outbreaks of the disease in widely distant parts of the world is identical with that originally isolated in Great Britain. Conclusive proof has also been obtained of the identity of the experimental disease in ferrets with influenza in man; an infection originally obtained from human sources and since passed repeatedly from ferret to ferret, has been retransmitted by accident to a human being. Progress has been made in the study of methods for the immunization of man against this disease by use of vaccines; but nothing suitable for application in more than an experimental way has yet been achieved.

A new method of determining the size of the particles of different viruses has been used to check results obtained by differential filtration. The rotor of a Sharples centrifuge, closed at the lower end, is lined with a thin layer of a weak agar gel, which is allowed to set during rotation: the suspension to be separated forms a layer only a small fraction of a millimetre in depth on the surface of the agar when the rotor is spinning, so that the particles become entangled in the gel and are protected from re-suspension when the rotor is decelerated. The correspondence between the figures given by filtration and centrifugation has been found in all cases to be a good one.

A characteristic of the known pathogenic viruses has been the failure, hitherto, to grow them in artificial culture media free from organized cellular material which they can infect. A group of free-living non pathogenic organisms, of about the size of vaccinia virus, has now been discovered living in London sewage; they grow readily on ordinary bacteriological media, in which they can be maintained indefinitely in pure culture. The suggestion that propagation of viruses is possible only under conditions of intra-cellular parasitism, since the system of enzymes and surfaces necessary for self-reproductive life could not exist within a sphere of such small diameter as that of a virus, is therefore inapplicable to viruses of the size of the vaccinia group—about 150 millimicrons. The existence of these free-living organisms raises the hope that means may yet be found for growing some of the pathogenic viruses in artificial culture.

Analysis of some recent studies of nutrition in Great Britain has shown the relative constancy in the distribution of calories between protein, fat and carbohydrate eaten by people in different towns: in particular, the percentage of protein eaten is constant, at 10–11 per cent in St. Andrews, Cardiff and Reading. In spite of this, the types of foodstuffs eaten are widely different: in fact, the constant percentage intake of protein and the similar calorie intake of people living far apart, are obtained independently of the type of foodstuff eaten and seem to represent the result of some kind of instinct. As regards the daily calorie intake, a recent investigation of the diet of more than a hundred women students showed the daily intake to be 2,035 calories per person. This intake is considerably less than the usual standard of 3,000 calories, which has itself been considered by some workers to be too low. The analysis of these diets led to the conclusion that few can be considered really poor: on the other hand, many of them, particularly with reference to their content of 'protective' foodstuffs such as milk, green vegetables and fruit, leave much to be desired. The remedy is the education of the average housewife in the relative nutritive value of different foodstuffs.

Epidemic diseases still remain one of the greatest enemies of mankind, although some have been partially or even completely conquered. Problems relating to the spread of epidemics have been studied by field investigations of epidemics naturally occurring among human beings; but there are still many problems which have resisted field investigation because the difficulties of collecting statistical evidence prevent the assessment of the importance of inter-related factors. The experimental study of the spread of epidemics in a population of mice, as carried out for many years at the London School of Hygiene and Tropical Medicine, has provided answers to certain of these problems. Thus it appears that in large herds living under conditions favourable to the spread of epidemic disease, and receiving regular additions of healthy animals, the disease will persist indefinitely. The form of the mortality curve and the size of the herd are determined mainly by the rate of immigration. In epidemics initiated by virulent organisms, the rate of mortality during the early days of herd life is high, reaching a low level between the fortieth and sixtieth days of cage life. The expectation of life from the twentieth to the thirtieth day rises continuously but never reaches that of normal healthy mice. It is considered that both selection and natural immunization play a part in the increased average resistance displayed by surviving animals, the latter being the more important.

Another important subject which is discussed in the report is the problem of the prevention and treatment of puerperal (or childbed) fever. Summing up the present position, the report states that modern investigation suggests two lines of prevention, with a reserve line of treatment if the first two lines of defence are broken down. First, childbirth should be so conducted that access of pathogenic organisms to the birth-canal is rigorously excluded, especially streptococci from the throats of medical attendants, friends or the patient herself. Secondly, the diet should be of such a nature as to raise the resistance to infection to the highest possible level; this means an ample consumption of milk, green vegetables and other protective foods. Finally, if infection does occur, there is evidence that the new chemotherapeutic compounds, 4-sulphonamido-2-4 diaminoazobenzol and *p*-aminobenzene sulphonamide, will reduce both the mortality and the incidence of complications.

Obituary Notices

Prof. W. M. Wheeler

IN the death of Prof. William Morton Wheeler, the United States loses an outstanding personality in the biological world and a man whose reputation spread far beyond the confines of his native country. The first intimation of his death received in England was a telegram from Dr. T. Barbour of Harvard University to Prof. J. Stanley Gardiner, on April 21. He died suddenly in Harvard Square, Cambridge, Mass., on the evening of April 19, after having only very recently returned from a journey in Mexico.

Born at Milwaukee (Wisconsin) on March 19, 1865, Wheeler graduated from the German-American Normal College in that city in 1884. In June 1885, he became a teacher of German and philosophy in the High School, Milwaukee, under George W. Peckham, a well-known student of spiders and social insects. In 1887 Wheeler became custodian of the public museum in his native city, and gave up this post in 1890 on being made a fellow of Clark University, under G. O. Whitman. He graduated Ph.D. there in 1892 and, in the same year, became instructor in embryology at the University of Chicago: in 1897 he was assistant professor. While at Chicago, Wheeler went on study leave to Europe (1893–94), working under Boveri at Wurzburg, and at Liège; he also occupied the Smithsonian table at the Naples Zoological Station. In 1899 he became professor of zoology at the University of Texas; in 1903 he was made curator of invertebrate zoology in the American Museum of Natural History, New York, and from 1908 until 1935 he was professor of entomology at Harvard University. In addition to the last-named post, he was dean of the Bussey Institution of that University from 1915 until 1929.

Much of Wheeler's early researches were in the domain of general zoology—especially morphology and embryology. Mention may be made of his work on the development of the urino-genital system of the lamprey (*Zool. Jahrb.*, **13**, *Anat.*; 1899): his contribution on the peculiar Annelid ***Myzostoma*** (*Naples Mitt.*, **12**; 1896) and his large treatises on insect embryology (*J. Morph.*, **3**; 1889: **8**; 1893) besides several articles written in German and contributed to the *Zoologischer Anzeiger*. Wheeler's work on insect embryology, it may be added, is still important to-day. This kind of occupation, however, failed to stisfy him: "My association with Peckham, Whitman and Patten," he wrote, "had converted me into a hard-boiled morphologist." Henceforth he devoted himself to the insect world and developed his predominant interest in ant life. On this subject alone he must have published more than a hundred and fifty papers, covering most aspects of their economy. On the systematic side he has left a great output of high-class work, but it was the living creatures which attracted him most and especially the peculiar relations of ants to other insects and to the plant world. In addition to his great text-book on ants (1910), in the Columbia Biological Series, the treatise of more than 1,000 pages on the ants of the Belgian Congo (1921–1922) is a monument to his industry and to the other workers who collaborated with him. Wheeler's lectures given at the Lowell Institute, Boston, in 1922 formed the basis of his book "Social Life among the Insects" (1923). This work was greatly amplified in the elaborately documented "Social Insects, their Origin and Evolution" (Paris, 1926; London and New York, 1928). In 1928 there were also published his books "Emergent Evolution and the Development of Societies" and "Foibles of Insects and Men". In 1931 there appeared the book "Demons of the Dust: A study in Behaviour"—an attractively written study of parallelism in evolution as revealed by two widely divergent insect types. His last book was "Colony Founding among Ants", published in 1933, but I believe that he left material for at least one other book at the time of his death. He was active to the very end, and some of his latest papers only came to hand a few weeks ago.

All who knew Wheeler—and his friends are scattered in many lands—will feel a sense of personal loss, for he inspired genuine affection and regard. Many will recall his keen sense of humour as revealed in his published addresses and other writings, or in telling a good story. During his teaching career, at the Bussey Institution, each year brought its quota of students who came to work under him. Many who have now made distinguished careers owe their start to Wheeler's counsel and guidance. His interest was mainly in the research man rather than the undergraduate. Having discussed a programme of work with a student, the latter was usually left to his own devices, for Wheeler rarely visited his students in the laboratory. All who brought their difficulties to him, however, found him both helpful and sympathetic. Wheeler possessed the faculty of inspiring confidence in his men and succeeded in stimulating their best efforts.

Wheeler was a man of simple tastes and with the mind of a scholar. Besides a knowledge of the classics, he was thoroughly familiar with several European languages. His favourite reading for a number of years past covered many aspects of philosophy, psychology and sociology, written in several tongues. With this background, ripened by extensive travel and first-hand observation in the tropics and other lands, he brought to bear a penetrating insight into his interpretation of the evolution and behaviour of social insects. As expositions of such phenomena his writings are unsurpassed.

Wheeler belonged to most of the chief scientific societies of America. He held the degrees of Sc.D. of Harvard and Chicago Universities and of LL.D. of the University of California. He was an honorary member of the Entomological Societies of France and Belgium and was one of the twelve honorary fellows of the Royal Entomological Society of London. His first visit to Europe was in 1893 and he last visited England in 1935, when he attended the British Association meeting of that year. He married Miss Dora Bay Emerson of Rockford, Illinois, in 1898, who survives him together with a son and a daughter.

A. D. IMMS.

Prof. L. Mangin

LOUIS MANGIN, former director of the Muséum national d'Histoire naturelle in Paris, died at Orly on January 27 last. Born at Paris on September 8, 1852, Mangin was of Lorraine origin. He first studied botany under Le Monnier at Nancy and then with van Tieghem at Paris. He became professor of natural sciences at the Lycée of Nancy when twenty-one years of age, and at Louis-le-Grand when twenty-nine. His first researches showed the influence of his teachers and were concerned with plant anatomy and physiology; his thesis for his doctorate was on the adventitious roots of Monocotyledons. In collaboration with Gaston Bonnier he undertook research on respiration, transpiration and carbon assimilation, with results which are of interest in the historical developments of these subjects. This was followed by investigations on the physiology of Basidiomycetes, pioneer work which has not been much added to in the fifty years which have since elapsed.

Mangin then turned his attention to the structure of cell membranes, and by his methods of microchemical analyses and differential staining laid the foundation of modern histological research; that on the membranes of Mucorineæ and Peronosporaceæ is still the basis of text-book descriptions.

From the physiology of fungi and the structure of membranes it seemed logical to pass to the study of fungal infections, and this Mangin did with such effect that he is rightly regarded as one of the founders of French phytopathology. His best-known investigations are those on the diseases of wheat, chestnut, vine (with Viala) and fruit trees; he also studied rots of timber.

In 1904, Mangin was appointed professor of the classification and natural families of Cryptogams at the Museum national d'Histoire naturelle in succession to Dehérain, who had held the chair since 1880, but as professor of vegetable physiology. Here his enthusiasm and administrative ability resulted in his being surrounded by a group of active workers—but in conditions which were surprisingly bad. He continued his investigations and became interested in phytoplankton. One aspect of his work which has not received the recognition due to it, was the attempt to add precision to the description of moulds. In 1920, he was elected by his colleagues to succeed Edmund Perrier as director of the Museum. His administrative duties, particularly heavy on account of the effects of the War, left him little opportunity for research, but he devoted what time he could spare to the study of phytoplankton. By the time he retired in 1931 he had extended the activities and raised the prestige of the Museum; but perhaps his greatest service was the building of the magnificent new Botanical Gallery at a cost of twenty million francs, of which the Rockefeller Institution gave five millions.

Louis Mangin showed his character in his work; when one met him he appeared somewhat reserved but alert and practical, though ever ready to extend to younger men courtesy of a kind suggestive of an older generation. J. R.

WE regret to announce the following deaths:

L. B. L. Belinfante, secretary of the Geological Society of London in 1916–30, and editor of the *Quarterly Journal* in 1890–1930, on April 10.

Dr. A. P. Wills, professor of mathematical physics in Columbia University since 1910, on April 17, aged sixty-four years.

News and Views

Royal Society: New Fellows

AT the meeting of the Royal Society held on May 6, the following fellows were elected: Dr. J. D. Bernal, lecturer in crystallography, University of Cambridge; Prof. A. C. Chibnall, assistant professor of biochemistry, Imperial College of Science and Technology; Prof. G. R. Clemo, professor of chemistry, Armstrong College, University of Durham; Dr. A. N. Drury, lecturer in pathology, University of Cambridge; Prof. H. Munro Fox, professor of zoology, University of Birmingham; Prof. W. E. Garner, professor of physical chemistry, University of Bristol; Dr. S. Goldstein, lecturer in mathematics, University of Cambridge; Dr. Percival Hartley, director of biological standards, National Institute for Medical Research; Prof. H. L. Hawkins, professor of geology, University of Reading; The Rev. J. E. Holloway, lecturer in botany, University of Otago; Dr. W. Hume-Rothery, Warren research fellow of the Royal Society; Dr. T. G. Mason, Cotton Research Station, Trinidad; J. Reid Moir, archæologist; Dr. M. L. E. Oliphant, assistant director of research, Cavendish Laboratory, Cambridge; Dr. C. F. A. Pantin, lecturer in zoology, University of Cambridge; Dr. D. R. Pye, deputy director of scientific research, Air Ministry; Dr. E. C. Stoner, reader in physics, University of Leeds.

Coronation Honours

THE following names of scientific workers and others associated with scientific work appear in the list of Coronation honours conferred by H.M. the King: *Barons:* The Right Hon. Christopher Addison, first Minister of Health, 1919–21, and Minister of Agriculture and Fisheries, 1930–31; Sir John Cadman, chairman, Anglo-Iranian Oil Company and Iraq Petroleum Company. *G.C.M.G.:* Sir Frederick Leith-Ross, chief economic adviser to His Majesty's Government. *K.C.B.:* E. J. Forsdyke, director and principal librarian, British Museum; Prof. E. Mellanby, secretary of the Medical Research Council. *K.C.M.G.:* Sir David Chadwick, secretary of the Imperial Economic Committee and of the Executive Council of the Imperial Agricultural Bureaux; Prof. A. P. W. Thomas, emeritus professor of botany, zoology and geology, Auckland University College, New Zealand. *Baronet:* Sir David Milne-Watson, president of the National Gas Council and Governor of the Gas Light and Coke Company. *Knights:* Prof. R. W. Chapman, professor of engineering, University of Adelaide, South Australia; Brigadier H. J. Couchman, surveyor-general of India; Dr. Allen Mawer, provost of University College, London, and director of the Survey of English Place Names; Colonel A. Olver, expert adviser in animal husbandry to the Imperial Council of Agricultural Research; Dr. R. H. Pickard, director of the British Cotton Industry Research Association; Dr. D'Arcy W. Thompson, professor of natural history, University of St. Andrews. *C.H.:* Prof. C. T. R. Wilson, for services to experimental physics.

C.B.: Major-General H. M. Perry, honorary surgeon to the King, director and professor of pathology, Royal Army Medical College; Dr. D. R. Pye, director of scientific research, Air Ministry; B. Rackham, keeper, Department of Ceramics, Victoria and Albert Museum. *C.M.G.:* A. J. Findlay, director of agriculture, Zanzibar; C. F. M. Swynnerton, director of tsetse research, Tanganyika Territory. *C.I.E.:* J. F. Blakiston, director-general of archæology in India; Colonel J. Taylor, director, Central Research Institute, Kasauli; Lieut.-Colonel C. Newcomb, chemical examiner to the Government of Madras, and principal, Medical College, Madras; F. Ware, officiating expert adviser in animal husbandry to the Imperial Council of Agricultural Research.

C.B.E.: Prof. A. L. Bowley, emeritus professor of statistics in the University of London; Prof. E. L. Collis, emeritus professor of preventive medicine in the University of Wales, a member of the Miners' Welfare Committee; G. S. Colman, member of the Pastoral Research Council, Commonwealth of Australia; Dr. A. D. Crow, director of ballistics research, Research Department, Royal Arsenal, Woolwich; Colonel J. Heatly-Spencer, honorary physician to the King, professor of tropical medicine, Royal Army Medical College, and consulting physician to the Army.

O.B.E.: W. P. Brewis, chairman of the Newcastle Society of Antiquaries, member of the Council of the Roman Society; H. J. Burrell, for contributions to natural history in the Commonwealth of Australia; R. Daubney, chief veterinary research officer, Kenya; H. N. Linstead, secretary and registrar of the Pharmaceutical Society of Great Britain; A. Main, chief inspector of agriculture, Department of Agriculture for Scotland; A. Morley, lately staff inspector, Board of Education; Prof. A. J. Perkins, formerly director of agriculture in the State of South Australia; F. S. Richards, deputy surveyor-general to the Egyptian Government; H. W. Simmonds, entomologist, Fiji; Dr. J. M. Stagg, senior technical officer, Meteorological Office, Air Ministry; D. Stewart, deputy conservator of forests, United Provinces; J. G. Stewart, chief inspector of agricultural education, Ministry of Agriculture and Fisheries. *M.B.E.:* W. L. Watt, agricultural officer, Kenya; L. F. Wacher, agricultural officer, Basutoland. *I.S.O.:* A. H. Cockayne, director-general, Department of Agriculture, Dominion of New Zealand; A. More, deputy Government chemist.

Prof. W. L. Bragg, O.B.E., F.R.S.

PROF. W. L. BRAGG, who has been appointed director of the National Physical Laboratory, has held the Langworthy chair of physics in the University of Manchester since 1919. Beginning his research work at Cambridge in 1912, about the time when v. Laue had announced his discovery of the diffraction of X-rays by crystals, Prof. Bragg was attracted to this field of work. One of his early papers explained, in terms of the 'reflection' principle, the nature of the patterns observed in the Laue photographs. Along with his father, Sir William Bragg, he developed the X-ray spectrometer. The determination of the structures of the simpler crystals followed, until in 1915, their work was recognized by the joint award of the Nobel Prize for Physics. After his appointment at Manchester, Prof. Bragg quickly established a school of workers engaged in investigations of the solid state of matter. His own particular interest has been in the orderly arrangement of atoms in crystals and in relations between atomic arrangement and the properties of a crystalline substance. The field is a very wide one, and is of interest, not only to the physicist, but also to the chemist who is seeking to understand the nature of the forces which bind atoms together and to the industrial research worker who wants information about the structure of his working materials.

FOLLOWING the first period, in which the simpler crystal structures were investigated by X-ray methods, the determination of the structures of more complex crystals was made possible, principally through the development of methods of analysis using the intensities as well as the directions of reflection of the X-rays. In this phase of the work, Prof. Bragg and his co-workers have determined a range of complex structures of minerals, particularly silicates and zeolites. During the last few years, Prof. Bragg and his team of research workers have been particularly interested in an experimental and theoretical study of the atomic arrangements in alloys and in the effect of heat treatment on these structures. Prof. Bragg's laboratory in Manchester has been one of the principal centres in Great Britain for the investigation of the structure of crystals, and students from all parts of the world have visited the laboratory, either for training in this field of research or for the privilege of working under Prof. Bragg's supervision.

Prof. A. O. Rankine, O.B.E., F.R.S.

IT is announced that Prof. A. O. Rankine, professor of physics in the Imperial College of Science and Technology since 1919, will resign that position at the end of the present academic year in order to join the staff of the Anglo-Iranian Oil Company as chief physicist. Prof. Rankine has for some years acted as geophysical adviser to the Company and in his new position he will take charge of all physical investigations carried out by the Company. The appointment is another interesting and significant example of the migration from the academic to the industrial world of a distinguished man of science, and is evidence of the ever-growing importance of science and scientific research in modern industrial development. It may be remembered that Sir John Cadman, the chairman of the Anglo-Iranian Oil Company, was himself at one time a professor in the University of Birmingham. During his chairmanship of the Company, since 1927, notable work in the development of the relatively new science of geophysics has been carried out since 1924 by the Company, which introduced geophysical surveying in the country formerly known as Persia and now to be called Iran In the development of geophysical science, Prof. Rankine has played a notable part, and will no doubt find in his new sphere increased scope and opportunity for further advances.

Awards in Anthropology

THE Wellcome Gold Medal for research in anthropology for 1936 has been awarded by the Council of the Royal Anthropological Institute to Dr. Charles Kingsley Meek for an essay entitled "Law and Authority in a Nigerian Tribe". In accordance with the terms of award laid down when the medal was instituted by the late Sir Henry Wellcome, the subject of research is the application of the science of anthropology to the problems of administration among backward peoples. Dr. Meek was formerly an officer of the Nigerian administrative service, and has for long been known as the foremost authority on the native tribes of Northern Nigeria. He is the author of a number of works in which the ethnography of the territory has received detailed treatment. The Council of the Institute has also awarded the Rivers Memorial Medal to Dr. Edward Evan Evans-Pritchard. This medal is awarded in recognition of recent meritorious field work. On this occasion, the Council has had before it the results of Dr. Evans-Pritchard's work in the Anglo-Egyptian Sudan and in Kenya since 1926. Dr. Evans-Pritchard, who was educated at Exeter College, Oxford, and studied anthropology at the London School of Economics, was appointed in 1926 by the Sudan Government to carry on the ethnographical survey of the tribes of the Anglo-Egyptian Sudan which had been initiated by Prof. C. G. Seligman, and later for a time was professor of anthropology in the University of Cairo. He has also acted as honorary secretary of the Royal Anthropological Institute. From time to time, the earlier results of his researches have been published in *Sudan Notes and Queries* and in the *Journal of the Anthropological Institute*. His further studies have appeared recently in a work on witchcraft among the Azande, which has been pronounced by those most competent to judge to be one of the outstanding works of recent years in anthropology. Dr. Evans-Pritchard is now engaged in preparing a further work on the religion and social organization of the Azande.

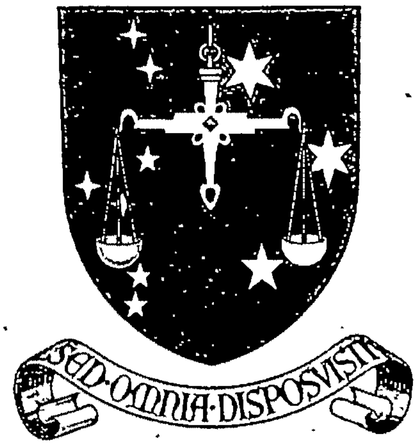
Wool Research in Australia

THE decision of the Australian Government last year, at the instance of pastoralists, to impose a levy on wool production, has been followed by the appointment of a Wool Board, with six members representing the industry and one the Commonwealth Government. The levy may be up to 6*d*. per bale, and the funds are to be used for (i) scientific research and (ii) publicity for the benefit of all sides of the wool industry. The Board has recently determined upon its expenditure under the first heading during the next financial year, and its decisions should result in marked stimulation of scientific work, particularly of that being carried on under the auspices of the Council for Scientific and Industrial Research. £2,750 has been granted for extensions to the Council's Nutrition Laboratory in Adelaide; £1,600 for sheep blowfly investigations at Canberra and Sydney; £900 for provision of additional accommodation at the McMaster Laboratory in Sydney; £730 per annum for three years for parasitological field work; £100 capital and £370 per annum for three years for further study of external parasites of sheep; £500 for the Council's field station at St. Mary's, some twenty miles from Sydney; £484 for three years for increased staff for fertility studies; and minor amounts for further investigations into toxæmic jaundice, foot-rot and ophthalmia in sheep.

IN addition to these grants, the Australian Wool Board has agreed to support a project for establishing in South Queensland a field station for large-scale investigations of sheep problems, including tests of methods for mitigating the blowfly pest. The Queensland Government has granted the Commonwealth Council a thirty years lease, at a peppercorn rental, of an area of 40,000 acres in the Cunnamulla district. Towards the capital expenditure on buildings, fencing, etc., that will be necessary, the Board has allotted £10,000 in the first year and £7,500 in the second. The establishment of this station is cordially approved by wool-growers throughout Australia, and it should serve as an effective additional link between the practical growers and the research workers in the city laboratories.

Arms for the British Association

THE British Association has received a grant of armorial bearings from the College of Arms, the necessary fees being met by gifts from an anonymous donor and from ex-presidents of the Association.



The shield is described as azure ten stars, two of six, four of five, and four of four points argent, representing the constellation of Libra; over all a balance or. The motto, *Sed omnia disposuisti*, is taken from "Wisdom of Solomon", ii, 20 (But Thou hast ordered all things in measure and number and weight).

University of Sheffield and Sir Robert Hadfield

IN NATURE of October 10, 1936 (p. 610), reference was made to the appeal for £250,000 being made by the University of Sheffield for urgently needed extensions and for endowments. The first list of subscriptions was headed by a gift of £10,000 from Sir Robert Hadfield, to whom the University was already indebted for valuable donations and much support. It is now announced that Sir Robert has increased his donation to £20,000, this being the largest individual gift so far received in answer to the appeal. The announcement was made in the course of his address at the annual meeting last month of Messrs. Hadfields, Ltd., and Sir Robert added that he was moved to add to his original donation by the noteworthy address delivered early last March by General Smuts on "The University in Civic Training", when he was installed as Chancellor of the University of Cape Town. General Smuts believes that the university is the hope of civilization, the one place where fact is exalted above sectional loyalties and ideologies. Sir Robert has given substantial proofs that he, likewise, has faith in the university as an institution of vital significance for the future of humanity. It is to be hoped that his great benefactions to the University of Sheffield will stimulate other industrialists to play their part in supporting more liberally, if not universities in general, at least the particular university to which they must look for development and progress in their own field. Sir Robert Hadfield, it may be noted, celebrated the fiftieth anniversary of his election to the Institution of Civil Engineers on March 1, when he received a congratulatory address from the president, and on March 23 was elected an honorary member of the Institution, for his "long and conspicuous service in the advancement of metallurgical science".

Decorative Lighting for the Coronation

SINCE the last coronation, twenty-six years ago, great improvements have taken place in the art of decorative lighting. In 1911, metal filament and arc lamps were used. Since then the invention of gas-filled lamps and the development of electric-discharge lamps have greatly cheapened the cost and improved the flexibility of the illumination. The illuminations will show many new aspects of London, and practically all the principal provincial cities will have very effective displays. In London alone there will be nearly two hundred floodlighting installations, and in the provinces, statistics obtained from six hundred local authorities show that the mean additional load per town will be approximately 60 kilowatts. This does not take into account the numerous smaller schemes of strip-lighting and illuminated devices with which shops and business premises will be decorated. For the first time, the fountains in Trafalgar Square are being illuminated by means of eight submersible reflectors taking 500-watt gas-filled lamps. In addition to all four sides of 'Big Ben', the terrace of the Houses of Parliament is being floodlighted for the first time. Two novelties are, 30-ft. high electric 'bonfires' with flame effects on the roof of the Shell Mex House, and colour changing equipment for illuminating 30-ft. high jets of water from fire floats stationed outside the new London Fire Brigade headquarters. A very large sodium floodlighting installation used at Dunfermline Abbey and Edinburgh Castle give an outstanding and beautiful display of decorative lighting.

The German Airship Disaster

THE latest and largest German airship, *Hindenburg*, was destroyed by fire while landing at Lakehurst, New Jersey, U.S.A., on the evening of May 6. This was the terminal point of her first voyage of the year from Frankfort-on-Main. She carried 39 passengers and 61 crew, approximately half of whom were killed or afterwards died of injuries. The airship had been cruising about for an hour during a heavy storm, which was judged to be too severe for safe landing, and was just coming in at about 300 feet above the ground, dropping her nose mooring lines for the landing crew on the flying field. Reports state that a burst of flame was seen at the stern. In a few moments the whole ship was enveloped in fire. This was evidently due to the ignition of the hydrogen in the gas bags, as the report mentions the exceptional brilliance of the fire. No details are yet available upon which any useful theories as to the cause of the fire can be based, but the fact that the ship had been cruising around the field in a heavy thunderstorm lends colour to the suggestion that she was electrically charged, and raises the possibility of sparks having occurred when the landing ropes earthed her. It is known that special precautions against this were embodied in her design, and therefore this theory assumes some additional accident. Whatever was the original cause of the accident, it is certain, as was the case with the British airship *R* 101, that the ignition of the highly inflammable hydrogen was responsible for the completeness of the disaster.

The Electrical Industry of the World

THE twenty-ninth report of the Imperial Economic Committee (London: H.M. Stationery Office. 2*s*. 6*d*. net) gives a survey of the trade in electrical machinery and apparatus. The latest information given relates to the year 1935. Perhaps the most significant feature during the last five years is the leading part that radio receiving sets have been occupying. At the end of 1935 there were 56 million sets of this type of apparatus in use, the increase having nearly doubled in five years. There were 22·5 million sets installed in the United States, and this works out to 178 per 1,000 of the population. The consumption of electrical energy used in radio receiving was 1,540 million kilowatt hours per annum. The corresponding figures for Great Britain, which was second in the world's list, was 7·4 million sets, and the third was Germany with 7·2 million. On the other hand, the increase in the world's telephones was comparatively small. This is ascribed primarily to an actual decrease in the United States and Canada. But these two countries still lead in this form of communication. It is worthy of note that there is a greater number of telephones per head of population in agricultural countries like Denmark, New Zealand and Australia, than there is in industrial countries such as Great Britain, Germany and France. Probably this is due to the greater facilities of communication by other methods in the latter countries. Russia has come to the front as an electrical manufacturing country. This is shown by the fact that the value of its imports, which rose gradually from 3·62 million pounds in 1929 to 9·15 million pounds in 1932, has fallen rapidly to only £789,000 in 1935. The outstanding example of self-sufficiency is the United States, the imports of which in 1935 were valued at only £427,000.

Present State of British Bird Ringing

THE 1936 report on bird ringing in the British Isles (*British Birds*, April 1937) supports what the 1935 report indicated, namely, that future progress lies not in increasing the sum total, but rather in increasing the proportion of adult birds over nestlings, and scarcer species, marked. Although the total of 48,663 birds ringed is below the number for previous years, the total of trapped adult birds, 19,235, is a record, while that for nestlings (where mortality is naturally high) of 29,428 is a decline on the previous years. Dr. H. J. Moon again heads the list of ringers with 5,280 birds ringed, including 1,332 lapwings, 975 song thrushes, 849 blackbirds and 587 starlings; Mr. G. Charteris marked 3,524 birds, 1,166 of which were chaffinches, and Mr. E. Cohen marked 3,024 birds, including 865 shearwaters. There is an increasing number of birds ringed by schools and societies, and the two bird observatories. The Oxford Ornithological Society marked 2,639 birds, Bootham School 1,656, Rugby School 1,050, the Midlothian Ornithological Club 813, the British Empire Naturalists' Association 158, the Zoological Society 511 and Leighton Park School 403. Totals of ringed birds are not quite so significant as the numbers of birds of rarer species marked. Among the ringings of the Oxford Ornithological Society, for example, were 67 kingfishers, Skokholm Bird Observatory marked 27 white wagtails and 20 Greenland wheatears, Mr. A. Maynall marked 409 nightingales, Mr. C. Wontner Smith marked 201 rooks, Rugby School marked 169 rooks and 62 carrion-crows, Leighton Park School marked 21 fork-tailed petrels, Dartington Hall School 12 cirl buntings, the Isle of May Bird Observatory a barred warbler, two bluethroats and a Continental coal tit. Of the national total, the most numerous species ringed were: 3,191 lapwings, 2,155 Manx shearwaters, 1,530 Sandwich terns, 1,271 common terns and 1,131 herring-gulls.

The National Institute of Agricultural Botany

THE seventeenth report of the National Institute of Agricultural Botany, Cambridge, is now available, and copies may be obtained on application to the Institute (Huntingdon Road, Cambridge). The work of the Institute is directed to supplying the farmer with unbiased information as to the seeds he sows, and the report deals with methods by which this information was obtained in 1936. New varieties of all farm crops are tested by the Institute as soon as they appear, the trials being conducted on a field-scale at six permanent stations in England, and in some cases at additional centres on a farmer's own land. In all cases, the varieties are grown just as they would be by the farmer himself. Every feature of the varieties is noted and the results are often extremely enlightening. For example, of all the new varieties of winter wheat that have been tested in the last ten years, only one has proved to be worthy of general recommendation by the Institute. This is the Dutch variety 'Juliana', which has in the past two years' trials given slightly better results than 'Wilhelmina'. The position with other crops is very similar, and it is clear that farmers will be well advised, before deciding to grow a new variety, to apply to the agricultural organizer for their county, or direct to the Institute, for information as to the merits of the variety in question.

"The Hero"

LORD RAGLAN writes in reference to the review of his book "The Hero" appearing in NATURE (March 27, p. 532): "Your reviewer . . . suggests that in the absence of documentary evidence I would feel constrained to deny the existence of Nelson and Napoleon. My contention is that in the absence of documentary evidence we should none of us have heard of Nelson and Napoleon." In reply, the reviewer says that, in effect, Lord Raglan appears to agree. In so far as Nelson and Napoleon are characters in the folk drama, they stand on the same footing as Robin Hood, Maid Marian and the rest. These two names, however, were not an effort of invention, but were chosen as those of the popular hero and bogey of the day. Their survival in this form is an effect of folk memory and not of documentary evidence, and their appearance in a ritual does not preclude their real existence, however incongruous their dramatic action. In this instance, the inference happens to be supported by documentary evidence. The conclusion to the contrary, however, that is, that without documentary evidence we should not know of their existence, is shown not necessarily to hold good. Approved documentary evidence is the only source of certain knowledge, and to this extent Lord Raglan is above criticism; but the archæologist maintains, on the other hand, that a legend may embody facts which may in certain conditions afford a clue to interpretation, when his evidence points in a certain direction. The story of the Minotaur may be ritualistic; but the setting of the Minoan civilization is the fact to which it gave Sir Arthur Evans the clue. It may be true that, strictly speaking, in the absence of documentary evidence we have no certain knowledge of Minos; but we have all heard and believe in the existence of the head of the great empire, for whom his name is the generic term.

Russian Railway Transport

AT the International Exhibition of Art and Technique in Modern Life which is to be opened in Paris this month, Soviet railway transport will be well represented, the principal exhibit being a working model of the new locomotive *SO* 17–635 which recently completed a successful test journey of 13,000 miles hauling a goods train of 1,200 tons. This engine is an outstanding development of the steam locomotive and, in its way, a pioneer, having been designed for the conditions of Middle Asia and the Far East where, owing to the scarcity of water, the provision of adequate supplies may represent as much as 40 per cent of the total cost of construction. The engine has a special tender equipped with radiators for condensing the exhaust steam, and tanks for collecting the condensate. After being passed first through an oil separator, the exhaust steam enters a turbine which drives the fans for cooling the steam when it reaches the radiators. In this way, with an initial supply of 10 tons of water, it is claimed that the engine can make a run of 627 miles without replenishment. The trial trip was organized for the purpose of testing the behaviour of this locomotive in severe winter conditions, with different kinds of coal, and on the steep gradients which are numerous in the mountainous districts. Travelling from Moscow to Vladivostok and back, it passed over eleven main lines of the U.S.S.R., and the long run, it is stated, was completed without a hitch. Further Soviet exhibits at the Paris Exhibition will include working models of other steam and electric locomotives and of new types of railway coaches specially adapted to Russian and trans-Siberian conditions of travel. The growth of railway transport in those regions is indicated by recent official figures, which show that in 1935 the total length of the railways in the U.S.S.R. was 52,500 miles and that last year they carried 990·8 million passengers and 484·2 million tons of freight.

Research in Tropical Medicine

THREE junior fellowships are offered immediately by the Medical Research Council for award to qualified medical men wishing to receive training with the view of careers in research work in tropical medicine. The fellowships will be tenable for three years. The stipend will be at the rates of £300, £400 and £500 per annum in the successive years, with an additional allowance during service abroad and necessary expenses. In three years' time, at least one senior fellowship will be available for candidates who have held the junior fellowships mentioned above. This will be awarded for a further period of three years, carrying stipend at the rate of £600–£750 per annum, with an additional allowance during service abroad and expenses. The time will be spent mainly in research work in the tropics. The Council is also prepared to consider immediate applications for senior fellowships from candidates who have had adequate experience in research work, whether already specially trained in tropical medicine or not. The Council further intends to establish in due course permanent and pensionable appointments for research work in tropical medicine, including senior posts. Members of this research staff will work partly in the tropics, and partly in institutions at home to which they will be severally attached. Further information can be obtained from the Secretary, Tropical Medical Research Committee, 38 Old Queen Street, London, S.W.1, with whom applications should be lodged not later than June 15.

Royal Geographical Society Awards

THE King has approved the award of the Royal Medals of the Royal Geographical Society as follows: The Founder's Medal to Colonel C. G. Lewis, for his surveys on the Miri Mission, 1911–12, in Iraq and Syria, 1918–19, and on the Afghan and Turco-Iraq Boundary Commissions; for the air survey of the Irrawaddy Delta, 1924; and for his promotion and encouragement of the exploration and survey of the Himalaya; The Patron's Medal to Mr. Lincoln Ellsworth, for his work in developing the technique of aerial navigation in the Polar regions, culminating in his successful flight across the Antarctic in 1935–36. The following awards have been made by the Council: The Murchison Grant to Mr. Ronald Kaulback, for his surveys in South-eastern Tibet; the Back Grant to Mr. L. R. Wager, for his work in mountain physiography; the Cuthbert Peek Grant to Mr. V. E. Fuchs, to assist him in his expedition to Lake Rukwa, East Africa; the Gill Memorial to Mr. George B. Barbour, for his work on the geology and geography of China.

Institution of Electrical Engineers Premium Awards

THE Institution of Electrical Engineers has made the following award of premiums for papers read during the Session 1936–37, or accepted for publication: Institution Premium to Dr. E. A. Speight and O. W. Gill; Ayrton Premium to Dr. D. Robertson; Fahie Premium to Col. A. S. Angwin and Mr. R. A. Mack; Kelvin Premium to Dr. T. E. Allibone, D. B. McKenzie and F. R. Perry; Paris Exhibition (1881) Premium to J. A. Sumner; Overseas Premium to Dr. A. L. Green, Dr. G. Builder and Dr. O. O. Pulley; Extra Premiums to Dr. P. Dunsheath, L. H. Harris, E. H. Jolley and F. O. Morrell; H. Trencham and K. J. R. Wilkinson; Mr. W. R. Debenham; Dr. W. Jackson, Mr. H. A. Thomas; Wireless Section Premiums to Dr. Benjamin, C. W. Cosgrove, and G. W. Warren (Duddell Premium); Commander F. G. Loring, W. L. McPherson and W. H. McAllister, T. L. Eckersley; Meter and Instrument Section Premiums to W. F. Randall; Dr. E. Hughes; Dr. C. Dannatt; Prof. J. T. MacGregor-Morris and Mr. V. A. Hughes; Transmission Section Premiums to H. G. Taylor (Sebastian de Ferranti Premium); J. Eccles.

Radio Communication Conference at Bucharest

THE Fourth Reunion of the Comité Consultatif International des Radiocommunications (C.C.I.R.) will take place in Bucharest on May 21–June 8. The previous meeting was held in Lisbon in 1934 (see NATURE Sept. 29, p. 490), and in the intervening three years the various national committees have investigated miscellaneous technical problems in connexion with radio communication. The matters under discussion at the present time include the study of the propagation of waves, direction finding, the measurement and means of suppression of the various types of interfering noise experienced in radio reception, and the improvement of transmitters, particularly from the point of view of frequency stability and the consequent reduction of inter-station interference. Other matters which will be discussed at Bucharest, and upon which it is evidently desirable to secure the greatest measure of international agreement, concern the allocation of wave-bands to the various types of radio-communication services, and the nomenclature employed in designating these wave-bands and the corresponding frequency ranges. It is anticipated that some twenty nations will participate in the Bucharest conference, and the British delegation will include representatives of the Post Office, National Physical Laboratory, British Broadcasting Corporation and the various manufacturing and operating companies.

Magnetic Disturbances and Auroras

Writing with reference to the notes on this subject in Nature of May 8, p. 790, Father J. P. Rowland states: "I greatly regret that by inadvertence I misread in my notes a horizontal force range in minutes of arc, before converting into gammas, as a declination range, and so gave the extreme declination range as 93′, whereas it should be 62′ as given in my letter to *The Times*. The extreme range in horizontal force, exceeding 620γ is correct. There was another notable magnetic disturbance from May 4^d 17^h to 5^d 18^h U.T. with ranges in declination and horizontal force of 28′ and 234γ respectively, probably associated with an elongated group of sunspots which crossed the central meridian on April 29."

Comets

Mr. L. E. Cunningham at Harvard has detected the periodic comet Grigg-Skjellerup. Its position on April 30^d 1^h 30^s U.T. was R.A. 6^h 59^m 0^s, N. Decl. 7° 53′ 27″, mag. 13. In the "B.A.A. Handbook" for 1937 the elements and also an ephemeris are given, perturbations being taken into account. Comparison with this ephemeris indicates that perihelion will be reached on May 23.0 U.T., which is about half a day later than the predicted time. Dr. M. Davidson has used observations from February 4 to April 1, forming normal positions, and finds that Comet 1937*b* (Whipple) is moving in an elliptic orbit with eccentricity 0·999619. The period is very long—about 300,000 years.

Announcements

At the request of the Council of the Royal Society of Edinburgh and in terms of the Bruce-Preller Lecture Fund, Prof. H. S. Taylor, of the Department of Physical Chemistry, Princeton University, will deliver an address on "Heavy Hydrogen in Scientific Research", at the ordinary meeting of the Society to be held on June 7.

Dr. W. T. K. Braunholtz has been appointed secretary of the Institution of Gas Engineers in succession to Mr. J. R. W. Alexander, who has been appointed general manager of the Associated Gas and Water Undertakings, Ltd., and of the East Surrey Gas Co.

Johnstone and Florence Stoney studentships of the value of £250 each for research in Australia have been awarded by the British Federation of University Women to Miss Mary Elizabeth King and to Miss Joyce Laing, who are both proposing to work on aspects of pathology. A similar studentship will be offered for the year 1938–39.

The annual congress of the Royal Institute of Public Health in conjunction with the Institute of Hygiene will be held at Margate on May 25–29 under the presidency of Lord Horder. Further information can be obtained from the Secretary, A. Seymour Harding, 28 Portland Place, London, W.1.

The French Academy of Medicine has awarded the Albert I of Monaco prize of 100,000 francs to Drs. Paul Bouin and Ancel for their work on the sex hormones and the interstitial glands in man.

Prof. Levaditi, of the Paris Pasteur Institute and member of the Academy of Medicine, has been nominated scientific director of the French League against the Venereal Peril.

The National Geographic Society announces by its News Bulletin that arrangements are being made to broadcast on June 8 a description of the total solar eclipse of June 9 next from either Canton or Enderby Island in the Central Pacific. The transmission will probably be from an anchored vessel, and will begin from time to time several weeks previous to the eclipse with a description of the preparations.

Messrs. Bernard Quaritch, Ltd., 11 Grafton Street, London, W.1, have issued a Catalogue (No. 531, 1937) of books on early medicine and surgery. The gem of the collection is a fine copy of the very rare first edition of William Harvey's "Exercitatio Anatomica De Motu Cordis", printed in Frankfort in 1628. Among other rare and interesting works listed may be mentioned Robert Wyer's "Antidotharius", containing recipes for plasters, salves, ointments, etc., J. Duchesne's "The Practise Of Chymicall and Hermeticall Physicke", William Turner's "Herbal", and a copy of the second edition of Jenner's "An Inquiry into the Causes and Effects of the Variolæ Vaccinæ".

Erratum.—In the course of the summary of the Huxley Memorial Lecture delivered by Sir Thomas Holland printed in Nature of May 8, p. 809, reference is made to the work of "W. T. Blandford". The name should, of course, have been "W. T. Blanford"; and we regret having overlooked the mistake made in the typed summary supplied to us and followed by our printers.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 845.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Rate of 'Organification' of Phosphorus in Animal Tissues

RADIOACTIVE isotopes as indicators in biological problems were first used by Hevesy[1]. Recent progress in the production of artificial radioactive substances makes this field of research one of the most promising, and ^{32}P, the radioactive isotope of phosphorus with a decay period of 14 days, has already been used as an indicator in animal and plant metabolism[2].

Prof. E. O. Lawrence, of the University of California, kindly gave one of us some pieces of metal from the Berkeley cyclotron. During a chemical analysis of them, we separated a fairly large amount of ^{32}P which we used in an investigation of some problems of the intermediary metabolism in rats. The following is a preliminary report on the distribution and the rate of 'organification' of injected sodium phosphate.

TABLE 1. LIPIDIC PHOSPHORUS

Tissue	Per gram of moist tissue		Specific activity
	Weight of P (mgm.)	Activity (R.U.)	
Liver	1·083	19·2 ± 0·6	(18·6) 17·8 (15·7)
Intestine	0·905	12·9 ± 0·5	(16·0) 14·4 (12·6)
Kidney	1·237	16·3 ± 1·9	(17·7) 13·2 (8·2)
Parenchyma	1·073	9·2 ± 0·7	(10·3) 8·5 (7·1)
Muscle	0·480	1·4 ± 0·1	(3·4) 2·9 (2·3)
Brain and medulla	1·822	0·9 ± 0·4	(1·7) 0·5 (−0·2)

A young rat was fed on a diet containing only fats and proteins and practically free from phosphorus and calcium, and was injected daily for four days with sodium phosphate containing ^{32}P; afterwards it was bled.

The tissues were successively extracted with hot alcohol and alcohol plus ether. The extracts purified with chloroform were mineralized with nitric and sulphuric acids, and the phosphorus determined according to Neumann-Gregersen. We call this fraction *lipidic phosphorus*. The residue of the alcohol-ether extraction is treated with cold trichloroacetic acid; in a fraction of the extract we precipitate directly ammonium phosphomolybdate (*mineral phosphorus*) and the second fraction is again mineralized in order to determine the *acid-soluble phosphorus*. In the mineralized residue of the two successive extractions we determine the *acid-insoluble phosphorus*.

The radioactivity of phosphorus belonging to each fraction was measured with an ionization chamber in arbitrary units (R.U.). Absorption of the β-rays by the precipitates, and also natural decay were taken into account. For the sake of brevity we omit the data referring to mineral phosphorus and to acid-soluble phosphorus. The main conclusions from these fractions are:

(*a*) That the specific activity of phosphorus, that is, the ratio between activity and weight of phosphorus, is about the same in all tissues examined, except in brain and medulla where it is distinctly lower.

(*b*) That there may be, judging from a comparison of the activities in the fractions of the acid-soluble phosphorus and the mineral phosphorus, some low organic compounds which are synthesized in muscle intestine and liver, from inorganic phosphorus.

Tables 1 and 2 show the weight of phosphorus, per gram of moist tissue, its radioactivity and its specific activity, for lipidic phosphorus and acid-insoluble phosphorus respectively. We give also the probable error of the radioactive measurements and the extreme limits of specific activity supposing the true error to be three times the probable error.

TABLE 2 ACID-INSOLUBLE PHOSPHORUS.

Tissue	Per gram of moist tissue		Specific activity
	Weight of P (mgm.)	Activity (R.U.)	
Liver	2·015	34·1 ± 0·7	(17·8) 16·9 (16·0)
Intestine	1·353	15·5 ± 0·5	(12·7) 11·5 (10·4)
Kidney	0·902	7·8 ± 1·0	(12·2) 8·7 (5·2)
Parenchyma	1·610	14·2 ± 0·7	(10·0) 8·8 (7·5)
Muscle	0·520	3·8 ± 0·2	(8·4) 7·3 (6·2)
Brain and medulla	0·892	1·2 ± 0·6	(3·1) 1·3 (−0·4)

Lipidic phosphorus (Table 1). Both activity and specific activity show a maximum for the phospholipids in the liver, intestine and kidney; they have medium values in the other parenchymous organs (spleen, pancreas, adrenals, testes, lungs, heart) and lower values in muscle and brain and medulla.

These results confirm the assumption of a fairly active metabolism of phospholipids in liver and intestinal mucosa which has been put forward by one of us[3] and Sinclair[4], and suggest an extension of the assumption also to the kidney. Moreover, they show that the participation of the phospholipids to intermediate metabolism is not limited to a substitution of fatty acid radicals in the molecule of phospholipids, but results, at least partially, in a complete synthesis starting from inorganic phosphorus, even if this is simply injected.

The differences which we have found depend evidently upon large differences in the rate of synthesis of phospholipids in different organs and therefore afford some hints on the problem of the function of phospholipids in cell economy.

Acid-insoluble phosphorus (Table 2). Though this fraction contains different phosphorated compounds, it is probable that the greater part consists of nucleoproteins, which are the most complicated products entering into the structure of living beings.

Due to the different content of nucleoprotein phosphorus of different tissues, one notes different activities per gram of fresh tissue; specific activity is relatively high in the liver and perhaps in the intestine, while it is roughly the same in muscle, parenchyma and kidney. Brain and medulla show a very low specific activity; that is, the rate of synthesis of nucleoproteins is minimal in nervous tissue, as we have seen for the phospholipids synthesis.

We thank the Radiation Laboratory of the University of California for the gift which made this investigation possible.

Reflection of Atmospherics at an Ionized Layer

WE have been studying the wave-form of the electromagnetic pulse radiated from a lightning flash known as an 'atmospheric'. Incidental to the observations which we have made, evidence has been obtained of the reflection of atmospherics at an ionized layer.

The atmospherics are received on a vertical aerial, which is connected through an aperiodic amplifier to a cathode ray tube. The spot on the screen of this tube is photographed on a film fixed to the external surface of a cylindrical drum, which rotates at a uniform peripheral speed of 900 cm./sec.

Some hundreds of wave-forms have been observed, and more than twenty of these show pulses, which appear to have been reflected from an ionized layer at a height above the earth of 78–82 km. Three photographs of wave-forms showing this feature are reproduced in Fig. 1 (*a*), (*b*), (*g*). The intervals of time elapsing between the arrival of the first pulse along the ground and the reflected pulses can be measured for from five to eight reflections at the ionosphere. Assuming the law of optical reflection at the ionosphere and at the ground, and that the ground and sky waves are propagated with the velocity of light, c cm./sec., these intervals of time, t sec., enable both the distance of the flash, d km., and the height, h km., of the reflecting ionized layer to be calculated from the relation

$$ct = 2\,n(h^2 + d^2/4\,n^2)^{1/2} - d,$$

where n is the number of reflections at the ionized layer. In the accompanying table (p. 838) the values of h and d, which satisfy a least square fit for the observed times, t, are tabulated. The fit is sensitive to a change of 1 km. in the value of the height and 10 km. in the distance, and the accuracy of the fit is indicated under $\overline{\Delta t}$, which is the mean difference in microseconds between the calculated and observed times. The height obtained, assuming the law of optical reflection, is not, of course, the actual height of the reflecting layer, but is the 'equivalent' height.

Independent evidence of the distance from the receiving aerial of the lightning is entered in the last column. Only for the first case is the distance in this column more than a rough estimate, and in that case observers at Flinders Island, distant 380 km., and at the Eddystone light, distant 450 km., reported lightning at the time of the observation. An observation with the cathode ray direction-finder taken simultaneously with the photograph of Fig. 1 (*a*) confirmed this direction. In the second case the distance is estimated from the deflection of a cathode ray direction-finder. In the last four cases visual observations of the lightning were made, and assuming that it came from clouds 6 km. above the ground, the distances given can be calculated.

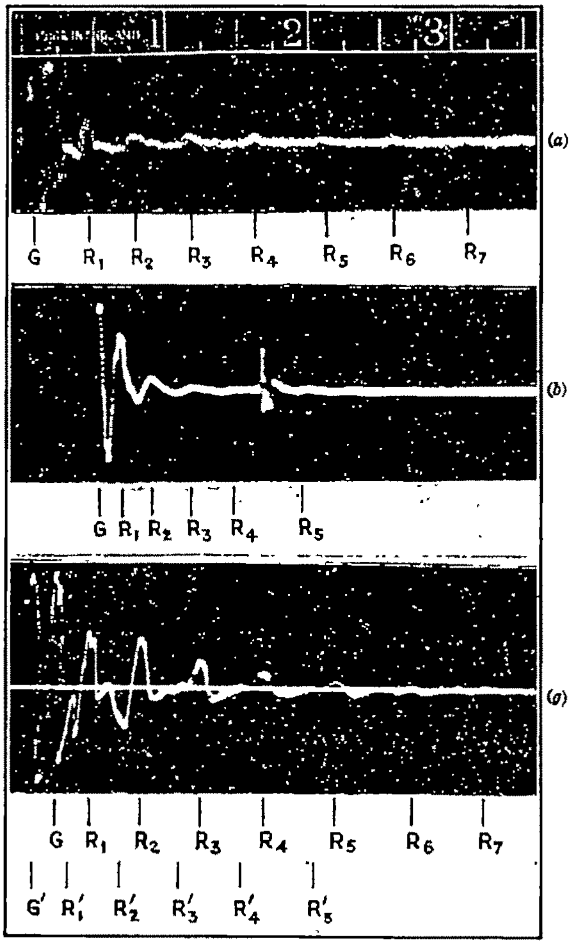

Fig. 1.

ATMOSPHERIC OSCILLOGRAMS FROM LIGHTNING DISTANT 175–500 KM. G IS THE GROUND WAVE AND R_1, R_2, . . . R_7 ARE THE REFLECTED WAVES. IN (*g*), TWO SETS OF REFLECTIONS G . . . R_7 AND G' . . . R'_5 APPEAR. ON THE TIME SCALE, 1 = 0·001 SEC.

The evidence for reflection rests on the close fit of the calculated with the observed times of the pulses, and upon the first case where there is independent evidence that the value of d so calculated is correct. Finally, the observations show that an atmospheric pulse has a fundamental frequency of the order of 10^4 cycles/sec. For a wave of this frequency, reflection will occur when the ionization reaches a value of the order of 1 electron per cm.^{3}, and this ionization no doubt exists at a lower height than the 90 km., which is given as an average value for the 'equivalent' height of the E layer.

Obs.	Time	Reflections	Height	Distance	$\overline{\Delta t}$	Estimated d
a	17 00	8	78 km.	410 km	10 μ sec.	420 km.
b	15 45	5	79 ,,	510 ,,	40 ,,	300–500 ,,
c	17 15	6	82 ,,	1310 ,,	50 ,,	Unknown
d	01 15	7	80 ,,	175 ,,	20 ,,	150 km
e	01 30	7	80·5 ,,	300 ,,	20 ,,	>250 ,,
f	01 45	6	79 ,,	300 ,,	10 ,,	>250 ,,
g	01 52	7	79 ,,	250 ,,	30 ,,	200 ,,

The observations *d*, *e*, *f* and *g* were taken on the early morning of February 20, 1937

These observations, taken at the University of Melbourne between November 1, 1936, and February 1937, have been made as part of the programme of work of the Radio Research Board of Australia.

Resonance in the Interaction of Radio Waves.

IN my recent account of a revised theory of the interaction of radio waves[1], mention was made of the following new deductions :

(a) In regard to the amount of modulation which a wave W can impress on another wave W', a notable degree of resonance may occur when the frequency of W passes through the value of the local gyro-frequency.

(b) A gyro-wave (that is, one having a frequency within a few per cent of this gyro-frequency) can produce observable interaction with suitable medium and long waves when it is radiated by its source at the rate of one or two kilowatts.

(c) The following conditions are favourable to the occurrence of gyro-interaction (that is, interaction caused by a gyro-wave) : The received wave W is reflected from a region of the ionosphere which lies within about 200 km. from a gyro-station, and has a wave-length which ranges approximately from 2,000 to 500 metres as the distance between the radiator and receiver of W' ranges from 400 km. to 1,200 km.

It was accordingly predicted that, among other broadcasting stations, Lille (247·3 metres) might be found to produce observable interaction with other waves.

This prediction has been confirmed and the deductions stated above have been amply supported by observations made by myself and many collaborators in different parts of Great Britain, Ireland, France and Belgium, during the period March 1–14.

Through the courtesy of Sir Noel Ashbridge of the B.B.C., Prof. René Mesny of Paris, Mr. T. J. Monaghan of Dublin, and other authorities, substantially the following scheme of experimental radiations took place: On separate nights, during 30 minutes between 0005 and 0045 G.M.T., the three gyro-stations Dublin (222·6 m.), London National (261 m.), and Lille, radiated respectively the morse letters Q, B and K on tones of 125 and 1,000 cycles/sec. and with a modulation depth of about 75 per cent. On one of these nights, for comparison of the effects produced, London Regional (342 m.) radiated the morse letter M on tones, modulation depths and powers similar to those of London National and in the intervals between the latter's B's. Corresponding respectively to the above three gyro-stations, the following three groups of complementary stations radiated at full power waves which, with the unintended exception of Hilversum I, were modulated only at five-minute intervals and then with characteristic morse letters having modulation depths of 2, 5 and 2 per cent respectively :

Athlone (531 m.) ;
Hilversum I (1875), Radio Paris (1648), Brussels I (484) ;
Hilversum I, Luxembourg (1293), Beromunster (540), Strasbourg (349).

It is not possible in this brief note to give more than a summary account of the results obtained, but a more detailed account will be published elsewhere.

The experiments with Dublin and Athlone failed to reveal any gyro-interaction, as might be expected with Dublin's power of 0·5 kW. and under normal conditions in the E-layer.

Lille impressed strong modulations on the waves from Hilversum I, Luxembourg and Beromunster when its radiated power was 60 kW., and occasionally weaker modulations when its power was 10 kW. On one of the latter occasions the interaction with the wave from Beromunster which was received at Leicester was strong enough to justify the conclusion that a power of 5 kW. would have caused observable interaction. Infrequently the wave from Strasbourg was also found to be modulated by Lille, and then weakly. Nearly all the ionospheric regions of reflection of the waves having the strongest impressed modulations are within 200 km. from Lille.

London National, radiating at 30 kW., impressed strong modulations on Hilversum I, Radio Paris and (less frequently) Brussels I. The depth of modulation at a low frequency was often about 3 per cent and at times considerably exceeded that of the received characteristic signal, which had been given a depth of 5 per cent. Several observers also heard an impressed modulation when the power of London National was only 5 kW. On one such occasion, Mr. E. W. B. Gill and I estimated that an impressed modulation with about half the intensity of that observed by us would still have been perceptible ; from this it may be concluded that a radiated power of about 2 kW. would have sufficed to cause observable interaction. Nearly all the ionospheric regions from which the most strongly affected waves were reflected lie within 200 km. of London.

The simultaneous radiations from London National and London Regional took place on the night of March 11–12. It was then found that, with equal radiated powers, the B's impressed by London National were usually stronger than the M's impressed by London Regional ; that often the B's were easily audible when all the M's were absent ; and that occasionally the B's were weaker than the M's. Having regard to probable deviations from complete symmetry in the radiation from each of the two stations, it may be concluded that with a given power London National causes stronger interaction than London Regional. Since their waves are respectively 11 and 45 per cent longer than the local gyro wave-length 235 metres, this result strongly supports the conclusion that resonance exists.

In the experiments with Lille, London National and London Regional, it was usually found that the intensity of the impressed modulation decreased as the modulation frequency increased. This is in accordance with the theory. But on several occasions the intensity with a modulation frequency of 1,000 cycles/sec. was observed to be much stronger than that with a lower frequency: an interesting anomaly in the theory in its present state.

A more complete account of the theory will be given in the issue of the *Philosophical Magazine* of May.

Cosmic Rays and the Magnetic Moment of the Sun

IT is generally assumed that the constant intensity of cosmic radiation at sea-level beyond a certain latitude is accounted for by the 'clocking effect' of the atmosphere, which absorbs all particles of energy below the limit of that latitude resulting from the action of the earth's magnetic field. An important consequence of this assumption is that the latitude at which the intensity becomes constant should be displaced towards the geomagnetic poles as the altitude above sea-level increases, since then the thickness of the absorbing air layer decreases and therefore also the energy absorbed. Compton's mountain experiments[1] already throw doubt on the existence of this displacement, and this doubt is strengthened by Cosyns's stratospheric measurements[2] which, while admittedly inconclusive, indicate that the intensity remains constant north of 49° even at the highest altitudes reached.

There are clearly two possible interpretations of this remarkable result. Either the spectrum of primary cosmic radiation has a sharp threshold at the energy corresponding to the geomagnetic threshold at that latitude where the intensity becomes constant, or else, as suggested by Janossy[3], particles of this energy (and less) are prevented from reaching the earth by the action of the sun's permanent magnetic field, although the moon might also be suspected.

The theory of the allowed cone of cosmic radiation[4] gives for the geomagnetic threshold at 50° about 200 millistormers (mS.) for particles coming horizontally and 300 mS. for particles coming from all directions. The number r_e measuring the energy of a particle in stormers is connected with the ratio of momentum to charge (mv/e) by Stormer's well-known relation

$$r_e = \sqrt{\frac{mv}{eM_e}}\, R_e, \qquad (1)$$

where M_e is the earth's magnetic moment and R_e the earth's radius. Introducing a parameter r_s similar to r_e, but referred now to the sun's magnetic dipole moment M_s and to the distance from the sun to the earth, D, by the relation

$$r_s = \sqrt{\frac{mv}{eM_s}}\, D, \qquad (2)$$

the same theory shows that, if the ecliptic lies along the solar magnetic equator, r_s must be less than 0·414. Eliminating mv/e from (1) and (2), we obtain:

$$M_s = M_e \left(\frac{D}{R_e}\right)^2 \left(\frac{r_e}{r_s}\right)^2; \qquad (3)$$

which, upon inserting the known magnetic moment of the earth and the known ratio D/R_e, gives $M_s = 10^{34}$ E.M.U. If the angle between the sun's magnetic moment and its axis of rotation is small, this value is only slightly changed. It corresponds to a field intensity at the sun's equator of 30 gauss, in good agreement with the results obtained by Hale and his collaborators[5] from a study of the Zeeman effect of solar lines.

It may be readily shown that, while the sun's magnetic field may thus prevent cosmic particles of energy around ·200 mS. (2×10^9 eV. if electrons, $1·6 \times 10^9$ eV. if protons) from ever reaching the earth, if they come from distances large compared with the diameter of its orbit, it does not hinder low-energy particles of suitable angular momentum shot off the sun from reaching the earth, provided either that such particles leave the sun at very high latitude or that its magnetic moment is inclined at a high angle (around 45°) with respect to the ecliptic. This introduces a difficulty in connexion with Birkeland's and Stormer's theory of the aurora polaris, particularly if the particles responsible for the aurora originate in the sunspot belt.

If the interpretation suggested here is correct, there are several consequences which may be accessible to experiment, of which we shall name only two. First there should be a seasonal variation of the intensity of cosmic radiation of lowest energy of the order of magnitude of the eccentricity of the earth's orbit, with maximum in summer and minimum in winter, arising from the fact that as the earth rotates around the sun the distance between them varies periodically. Secondly, there should be a diurnal variation as a function of solar time with phase which is now being calculated. It arises because the sun's field at the earth is still capable of deflecting particles of energy up to 435 mS. approximately, and therefore there is at the earth both a solar allowed cone and a terrestrial allowed cone, the common region of which varies periodically as the earth rotates around its axis. The magnitude of this fluctuation may be roughly estimated at between 0·1 and 0·2 per cent.

It may be added that the possibility of ascribing the blocking of cosmic particles to a magnetic action of the moon seems excluded on the ground that it would have to possess a magnetic moment about ten thousand times that of the earth; this would give rise to large variations of intensity depending on the position of the moon which have not been found.

Molecules in Interstellar Space?

IN a recent note in NATURE[1], and more in detail elsewhere[2], Dr. T. Dunham, jun., has described his discovery of more interstellar lines due to K (λ 7699·03), Ca (λ 4227), Ti+ (λ 3242·6 and others) and a number of other lines the origin of which has not yet been traced (λ 3957·7, λ 4300·3, λ 4232·6). We have to add to these Merrill's interstellar lines[3] (λ 5780, λ 6284).

Dunham's work and his discussion of the occurrence of Ti+-lines forms a landmark in the story of interstellar investigations, as it throws clear light on the mechanism of excitation, and removes a good deal of misconception arising out of the former idea that only Ca+-lines, and the sodium *D*-lines occur in interstellar space.

Dunham's discovery that only such Ti+-lines which arise from absorption in the lowest orbit of Ti+ ($3d^2$. $4s$. $^4F_{3/2}$) occur as interstellar lines and that no Ti+ atom in the next excited state Ti+ ($3d^2$. $4s$. $^4F_{5/2}$, excitation potential 0·012 volt) occur in interstellar space, shows that the reaction between matter and radiation in interstellar space is of a kind which cannot be described in terms of any interspace temperature. The temperature in interspace is very nearly absolute zero, and ionization is produced only by the photochemical action of quanta meeting atoms or ions after long intervals of time in space. The recombination between ions and electrons also take place at very long intervals. The result is that only such states of atoms and ions occur in interstellar space as have infinitely long life.

The argument raises the question: Why should not molecules also occur in interstellar space? In fact, the above arguments, if forced to their logical conclusion, lead us to the view that we should have molecules in interstellar space. Merrill in fact notes that the lines λ 5780·4, and λ 6284·0 discovered by him are diffuse, and in course of a conversation told me that they might be molecular in origin. In fact, the line λ 6283·0 appears decidedly to be due to *molecular sodium*, Na_2, due to the transition (Na_2: $^2S\,^2S\ A\ ^1\Sigma \rightarrow {}^2S.{}^2P\ B\ ^1\Sigma$, $n'' = 0$, $n' = 8$). This band is obtained in absorption in molecular sodium, and according to the Franck-Condon principle, the transition is strong as r'' (internuclear distance at the lowest state) is $3{\cdot}07 \times 10^{-8}$ cm., and r' (internuclear distance at the excited state) is $3{\cdot}66 \times 10^{-8}$ cm., so the transition $n'' = 0$ to $n' = 8$ is the most probable. According to the arguments presented here, no other line (or band) of Na_2 is likely to occur among the interstellar lines.

Merrill's other line (λ 5780) may be provisionally identified with a line of NaK ($n'' = 0$, $n' = 5$), though in this case the identification is less sure.

The molecule which is likely to be most abundant in interstellar space is H_2, but as it gives absorption lines only in the Lyman region, there is no possibility of our being able to prove its existence, but lines due to hydrides may be found amongst interstellar lines.

A Possible Function of the Osphradium in the Gastropoda

DESPITE the universal occurrence of the osphradium in the mantle cavity of marine Gastropoda and the large size to which it may attain, the current views as to its function are unsatisfactory. It has been considered (*a*) an organ for testing the water which enters the mantle cavity (Bernard[1]), and (*b*) as a chemo-receptor concerned with the detection of food in water (Henschel[2], Brock[3]).

But the sea is a very constant medium, apart from regions near the shore or the mouths of rivers, and the osphradium is present in Gastropoda which live in the open sea under conditions where the water is never contaminated or diluted. There is certainly no correlation between the presence, or size, of the osphradium and the possible need for 'water testing'. The second theory can at best have only a limited application, namely to predacious carnivores or carrion feeders such as *Nassa* and *Buccinum* (studied by Henschel[2] and Brock[3] respectively). It cannot apply to browsing herbivores, for example, *Pterocera* (Yonge[4]) or *Littorina*, deposit feeders such as *Aporrhais* which seek for food with the proboscis (Yonge[5]), or plankton feeders such as *Vermetus* (Yonge[4]) or *Crepidula* (Orton[6]). Yet in all these, with the exception of *Crepidula* where it is reduced, the osphradium is well developed. Moreover, there is nothing in the evidence produced by Henschel or by Brock inconsistent with the possibility that the siphon is the chemo-receptor in carnivorous species. This possibility is being investigated by us.

An alternative theory as to the function of the osphradium has been developed by us as the outcome of work on the ciliary currents in the mantle cavity of *Aporrhais* (Yonge[5]), followed by comparative work on a variety of common marine Prosobranchs and Opisthobranchs. It is suggested that the osphradium is concerned with the *estimation of the amount of sediment* carried into the mantle cavity by the water currents created by the lateral cilia on the gills. Our reasons may be summarized as follows:

(1) Material carried into the mantle cavity is divided into three portions. The heaviest material is removed by way of the inhalent aperture by cilia lining the mantle in this region. The finest material is carried between and over the gill filaments and entangled in the mucus from the hypobranchial gland before being expelled via the exhalent aperture. Medium-sized particles are accumulated invariably *along the line of the osphradium*, before being carried across the floor of the mantle cavity to the exhalent aperture.

(2) The osphradium, besides possessing sense cells (well described by Bernard[1] and by Stork[7]), also possesses very many mucous glands. The secretion of these masses gathers together the material which accumulates on the osphradium. Previous workers have made no suggestion as to the function of these glands.

(3) There is a general correlation between the development of the osphradium and the degree of sediment to which the animal is exposed. For example, it is broad in mud- and sand-dwelling Prosobranchs, such as *Buccinum*, *Nassa*, *Pterocera*, etc.; linear in passive burrowers such as *Aporrhais* and plankton feeders such as *Vermetus*; reduced in *Crepidula*, which is a plankton feeder normally raised

above the bottom. In *Patella*, where secondary gills have appeared, the osphradia are vestigial because material is not normally carried into the reduced mantle cavity, while in the Opisthobranchs, *Scaphander* and *Aplysia*, it is reduced probably in correlation with rejection of sediment by cilia on the edge of grooves on the parapodia which conduct the water currents into the mantle cavity.

It is therefore suggested that the sense cells in the osphradium form a tactile organ which responds to contact stimuli, the impulse being conveyed by way of the osphradial nerve to the visceral ganglia. Blocking of the mantle cavity with sediment is a supreme danger to Gastropoda, and the importance of such a receptor is clear. The invariable association between ctenidum and osphradium is explained on this view, because the former creates the current, in which the quantity of sediment is estimated by the latter. The universal presence of the osphradium, irrespective of the habitat and of the food, is also explained. It is hoped later to follow up this biological study with an experimental analysis of the receptive capacities of the osphradium.

Lunar Periodicity in *Homo sapiens* L.

THE belief in a connexion between sexual periodicity and the moon is very ancient[1]. In particular, it is commonly thought that there is some connexion between the moon and menstruation. De Lee[2] stated, without giving any evidence, that the majority of women menstruate during the new moon, thus associating the periodicity with the *synodical* lunar month of 29·55 days. Arrhenius[3] concluded from data of nearly 12,000 menstruations that there is a slight *tropical* lunar rhythm of 27·32 days, and that the average duration of the menstrual cycle is just under 27 days.

We have reinvestigated these questions with data of more than 10,000 menstruations. We find a great variation in the duration of the cycle, both in one individual and between different individuals. The average duration in our cases during 1928–30 was 29 days, but there was a clear inverse correlation between age and the duration of the cycle. Thus the cycle became shorter by a day with every five or six years increase in age, the oldest group (born before 1891) giving an average of 26·9 days, and the youngest (born after 1905) of 30·2 days. If, therefore, the average cycle of one age-group is equal in length to any lunar cycle, then this equality will not be present in any other age-group. Similarly, if the average for a whole population corresponds with a lunar cycle, the correspondence is unlikely to be present in another population having a different age-distribution. Since Arrhenius's average for the menstrual cycle was derived from data which mostly gave the time interval in whole weeks, while in ours the individual averages err by not more than ± 0·1 day, his conclusion can no longer be accepted.

An exhaustive examination of the number of our cases starting to menstruate on each day of each kind of lunar month has been made, involving statistical and graphical tests. *No correlation* of any kind was found. Arrhenius's data were known by him to be inaccurate, and they showed a systematic error, inherent in their mode of collection, which itself could give the appearance of a lunar periodicity. Our data are far more accurate and do not contain this source of error. We therefore conclude that there is no causal relation between the moon and menstruation, and that the well-known *approximate* coincidence in the duration of the cycles is fortuitous.

A full account of this investigation, embodying a number of other conclusions, will appear in October in the *Journal of Obstetrics and Gynaecology of the British Empire.*

Action of Radium Rays on the Growth of Cells *in Vitro*

NUMEROUS experiments on gamma irradiation of cells cultivated *in vitro* have demonstrated their high radio-resistance to doses designed to produce a lethal effect. Sub-lethal doses have the effect of producing changes in the mitotic activity of the culture, while the lethal dose has so far only been observed as a delayed effect.

In continuation of our earlier experiments[1] we tried to work out a suitable dosage and method of application which would enable us to produce in the irradiated culture *itself* graded effects of radium from very slight inhibition of growth to death of the whole colony.

This was achieved in the following way. The source of rays consisted of a plate 1 sq. cm. in area, containing 5·9 mgm. of radium element with a filter of 0·05 mm. monel metal. With this filtration and with the use of a mica plate of 0·15 mm. thickness for the culture, 12 per cent of the soft and 58 per cent of the hard β-rays were available, in addition to the α-rays. By means of a simple centralizer, it was possible to conduct all the experiments under identical irradiation intensities. The radiations were applied to pure cultures of chick's mesenchyme cells cultivated in the hanging drop according to Carrel's method.

In contrast with most investigations hitherto published, irradiations were carried out in a refrigerator at +6° C. By this method of irradiation in the cold, we succeeded in investigating the various effects of radium treatment on the irradiated culture itself.

In all cases where more marked effects are to be produced by prolonged exposure, it is absolutely essential to suspend active cell life during the whole period of irradiation. With the usual method of treatment in the warm, the cells continue to migrate and divide during irradiation and the culture proceeds to develop; however, if the activity of a culture is suspended by cold, it accumulates the total effect of the rays, without manifest change. When a culture irradiated in the cold is transferred to the incubator, it develops to a degree exactly corresponding to the dose of rays applied. We are thus enabled to establish a numerical relation between the amount of growth inhibition and the dose of rays applied.

The cultures are irradiated immediately after explantation and are then transferred to the incubator. A parallel non-irradiated control culture is set up under identical conditions.

In our experiments, the cell cultures react to dosages ranging from 0·3 mgh. to 206·5 mgh. (3 minutes to 35 hours exposure) as observed in a period of 3 × 24 hours. The effects can be divided into three groups:

(1) Growth inhibition without complete stoppage of growth within the period of observation. The doses employed ranged from 0·3 mgh. to 70·8 mgh.

(2) Marked inhibition of growth with subsequent cell degeneration and stoppage of growth of the culture within the period of observation. Doses: 70·8–177 mgh.

(3) Immediate death of the irradiated culture. Doses 188·8–206·5 mgh.

With doses of less than 47 mgh. the retardation of growth in the irradiated cultures is observed after a latent period of 24 hours. With doses greater than 47 mgh. this latent period is no longer apparent.

Radioactivity induced by Fast Neutrons according to the (*n*, 2*n*) Reaction

IN a letter to NATURE[1], we reported some time ago that we had obtained evidence for the expulsion of two neutrons from the nucleus when copper and zinc were bombarded with the fast neutrons from a (Li + ^{2}H) source. In the case of copper, our assumption was confirmed by the experiments of Bothe and Gentner[2], who obtained the same radioactive copper nucleus by irradiating this element with gamma rays, this giving rise to the expulsion of a neutron. According to the latter process the same investigators produced some new radioactive bodies. We attempted to get the same active isotopes with the fast neutrons from our (Li + H^2) source according to the process (*n*, 2*n*), the results being as follows.

Molybdenum. A strong activity is observed with a period of 21 minutes. Bothe and Gentner found a period of 17 minutes, whilst a 25-minute period is observed with slow neutrons[3]. With slow neutrons (Be + ^{2}H + paraffin; intensity equivalent to 3 grams Ra + Be) we also find a 25-minute period, which indicates that these activities are not identical.

Silver. A sheet of silver with a filter of 0·4 mm. silver and 0·2 mm. cadmium in front of it was irradiated. In accordance with Bothe and Gentner, we found a period of 24 minutes. The 2·4-minute period is also present.

Bromine. The activity induced in bromine shows two periods, one of 18 minutes and one of about 5 minutes. The former has been observed also by Bothe and Gentner. For the short period they give 3·5 minutes however.

Antimony. A strong activity with a period of 17 ± 1 minutes is observed, whilst Bothe and Gentner give 13 minutes.

Tantalum. A sheet of pure metallic tantalum was irradiated several times for half an hour. Only a very poor activity was obtained. We could not establish the period. Bothe and Gentner found a 14-minute period.

Tellurium. A strong activity with a 60-minute period is observed. The same period was found by Bothe and Gentner.

It may be mentioned that our apparatus works at a tension of 250 kV., whilst almost pure deuterium is used. Hence the creation of gamma rays is excluded.

Continuing our experiments, we observed some more examples of this type of reaction and found some new radioactive isotopes:

Selenium becomes strongly active when bombarded with fast neutrons. The period is 56 minutes. With slow neutrons (source as mentioned above) we find a period of 22 minutes, whilst Fermi and his co-workers[4] give 35 minutes.

Cadmium bombarded with fast neutrons yields two periods, one of 200 minutes and one of about 20 minutes. These activities may be due to ^{109}Cd and ^{115}Cd. A very low activity with a period of 70–200 minutes has already been observed when cadmium is bombarded with slow neutrons.

Mercury gives a period of 43 ± 1 minutes when bombarded with fast neutrons. With slow neutrons this period was not observed. A chemical separation was attempted by R. W. P. de Vries. It was ascertained that the active nucleus is an isotope of mercury.

Thallium. With fast neutrons we obtained a period of 4·1 minutes. As a period of 4 minutes has been observed already with slow neutrons[5], we may ascribe this activity to ^{204}Tl.

Absorption Spectra, Optical Activity and Isotopic Exchange

WE have made a systematic examination[1] of the absorption spectra of cobaltammines which undergo isotopic exchange of hydrogen atoms in constituent NH_3 or NH_2 radicals, and more especially of those which are mixtures of optical isomers. Cobaltammines almost invariably give rise to two broad absorption bands[2] in the visible (I) and near ultra-violet (II) spectrum. Substitution of ^{2}H for ^{1}H produces an effect upon band (I) illustrated in Fig. 1; it is generally more pronounced the larger the number of exchangeable hydrogen atoms in the molecular ion. Absorption band (II) is scarcely affected, but differences occur in the farther ultra-violet. The full line is representative of protium-containing cobaltammines, the broken line of corresponding deuterium compounds.

The form of the curves of rotatory dispersion obtained by Mathieu[3] for protium-containing cobaltammines dissolved in water suggests that the regions of absorption responsible for optical activity are precisely those which we have found sensitive to protium-deuterium exchange; notably the long wavelength side of band (I). Accordingly we have compared the rotatory powers of the protium and deuterium isomers of cobalt tri-ethylenediamine ion, the number of complex ions in the path of the beam being identical in each case; that is, $[Co(H_2N.CH_2.CH_2.NH_2)_3]^{3+}$, hereinafter called [H], dissolved in H_2O, and $[Co(D_2N.CH_2.CH_2.ND_2)_3]^{3+}$ hereinafter called [D], dissolved in D_2O. The observed rotations are tabulated; the solutions, approximately 0·035 molal, of lævo- [H] and lævo- [D] were rather more concentrated than those of dextro- [H] and dextro- [D].

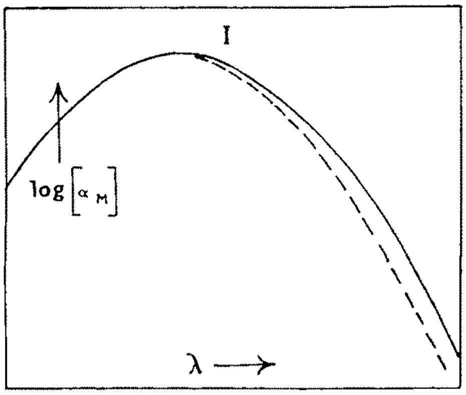

Fig. 1.

Wave Length	Lævo		Dextro	
(A.)	H_2O	D_2O	H_2O	D_2O
5893	−3·29°	−3·09°	2·86°	2·68°
5770	−4·18°	−3·90°	3·56°	3·31°
5461	−9·57°	−8·86°	8·03°	7·43°

As would be anticipated from the displacement of the absorption edge of band (I), the rotation of [D] is smaller than of [H] at all three wave-lengths; the percentage difference in rotation increases as the absorption maximum at 4665 A. is approached. A complete investigation of rotatory dispersion is contemplated. That the phenomenon is due to the exchange of ^{2}H for ^{1}H and not to other conceivable causes is proved by the following observations. Similar differences of rotation are ***initially*** observed when [H] and [D] salts are dissolved in pure formamide, but the rotation of the [D] solution gradually increases and after several hours becomes equal to that of the [H] solution which remains unaltered, indicating progressive substitution of ^{1}H for ^{2}H in the molecular-ion. The total number of exchangeable hydrogen atoms in the solvent is enormously greater than in the solute.

The slow exchange of hydrogen isotopes between cobalt hexammine ion and water was recently reported by Anderson, Briscoe, James and Spoor[4], who followed the process by measuring changes in density of the water. We infer from spectroscopic and polarimetric observations, that the corresponding reaction of cobalt tri-ethylenediamine ion is complete well within two minutes at 0° C. But the rate is easily measurable when [D] is dissolved in formamide containing a few parts per cent of H_2O, the rotation increasing with time to a final constant value. Conversely, the rotation of [H] in formamide containing a little D_2O falls at first and afterwards rises again. Therefore the fastest rate of isotopic exchange in the system, formamide—[*H*]—D_2O, is between [H] and D_2O. Whether the subsequent increase in rotation is produced by interchange between the deuteriumated complex ion and formamide or whether the D_2O—formamide exchange is partly, though indirectly, responsible cannot yet be decided. Clearly the latter process, if it takes place, is slow.

It seems likely that an indicator of isotopic exchanges more sensitive than $[Co(en)_3]^{3+}$ will be found amongst optically active co-ordination compounds.

Combined Ascorbic Acid in Plant Tissues

EVIDENCE was presented some time ago which indicated that a part of the ascorbic acid present in certain plant food materials was present in the combined state[1]. Mack[2], however, still considers that any apparent increase in the ascorbic acid value of cabbage on cooking is to be attributed to the thermal destruction of the ascorbic acid oxidase, and Levy[3], while recognizing that part of the ascorbic acid in certain plant tissues is in the combined state, records that he has observed a decrease in the ascorbic acid value of cabbage on boiling. Experiments with cabbage carried out here have, however, invariably shown a very considerable increase in ascorbic acid value on heating in a suspension of water on a boiling water bath for 15 minutes in an atmosphere of nitrogen or carbon dioxide. We believe that the oxidase theory accounts partly, but not quantitatively, for the observed increase in value. Thus alcoholic and ethereal extracts, containing no oxidase, also show increase in ascorbic acid value, on being heated for 5 minutes in an atmosphere of nitrogen on a boiling water bath, even when titrations are carried out after addition of formaldehyde or after mercuric acetate treatment, in order to eliminate interfering substances, if any (Table 1).

TABLE 1.

Figures are given in mgm. ascorbic acid per 100 gm. material.

	Direct titration		Titration after addition of formaldehyde to the dye		Titration after mercuric acetate treatment	
	cold	heated	cold	heated	cold	heated
Alcoholic extracts	7·10	9·00	7·10	9·00	5·60	6·75
	3·90	5·26	3·90	5·26	3·55	4·83
	1·50	2·34	1·50	2·34	—	—
Ethereal extracts	0	0·69	0	0·69	0	0·62
	0	1·02	0	1·02	0	0·75
	0	0·73	0	0·73	0	0·71

It will be seen from Table 1 that there is always an increase in the ascorbic acid values of the alcoholic and ethereal extracts on heating and that, although mercuric acetate lowers the figure (due, according to our observations, not merely to removal of interfering substances but also to a partial loss of ascorbic acid), the increase on heating is significant. In the case of ethereal extracts, the actual figures after heating are low owing to the low solubility of combined ascorbic acid in ether, but it will be observed that before heating the value is nil. Although there are naturally considerable variations in the increase among different cabbage samples, we have observed an increase on heating under our conditions of experiment in all cases without exception.

Further evidence of the presence of combined ascorbic acid in cabbage is provided by experiments (Table II), which show that treatment of cabbage suspensions and extracts with hydrogen sulphide in the hot condition gives a considerably higher value for ascorbic acid than similar treatment at room temperature (25° C.). Cold treatment with hydrogen sulphide, of course, always gives higher values than the simple method of extraction with trichloroacetic acid, owing to the reduction of the considerable quantities of dehydroascorbic acid present, but the difference between the effects of the hot and cold treatments with hydrogen sulphide indicates again the presence of combined ascorbic acid in cabbage, which is split up by heating. This difference can scarcely be explained on the basis of the oxidase theory, as cold treatment with hydrogen sulphide under our conditions of experiment should be capable of reducing all the dehydroascorbic acid produced by the action of the oxidase.

TABLE 2.

Figures are given in mgm. ascorbic acid per 100 gm material.

Effect of H_2S at 25°		Effect of H_2S on boiling water bath
Aqueous suspensions of cabbage	64·5	72·7
	67·0	73·0
	67·8	81·7
	62·5	71·6
	64·0	73·8
Aqueous extracts of cabbage	40·0	49·5
	34·6	41·6
	38·5	45·2
	40·0	47·2
Alcoholic extracts of cabbage	12·3	20·3
	9·5	15·0
	21·7	35·3
	24·0	30·0

Further, we have lately observed that chloroform extracts of dried cabbage, which, as such, give no titre with the indophenol reagent, do so after heating in an aqueous suspension, and at least 75 per cent of this reduction value disappears if the extract, after heating, is subjected to the action of a preparation of ascorbic acid oxidase. This is additional evidence for the view that the reducing substance, produced on heating, is very probably ascorbic acid. This view is being further tested by biological experiments.

Magnetic and Electrical Dimensions

I DOUBT very much whether Sir James Henderson[1] is justified in assuming that the members of the International Committee—and presumably also those of the various congresses and committees which have from time to time reaffirmed the decision that the permeability of space should be regarded as an entity having physical dimensions (the so-called Oslo convention)—were not as fully aware as he himself of "the implications of the adoption of Ampère's theory of magnetism". That their interpretation of these implications differs from his I do not doubt. When I read that "Prof. Howe would have us jettison . . . that wonderful machine which has produced the electromagnetic theory of light, to which is due the discovery of the quantum theory and all the other developments of modern theoretical physics", I can only smile and say that it sounds magnificently foolish, but bears little, if any, relation to the facts of the case. In his paper he showed that it was not only possible, but also very tempting, to assume that permeability is merely a numeric, and that in space the magnetic induction B and the magnetizing force H are one and the same thing. This is, however, a very old assumption; Gauss and Weber made it and on it built the electromagnetic system of units, but they never deceived themselves into thinking that it was anything more than a conventional assumption. Sir James is mistaken in thinking that I object to the mathematical nature of his arguments; on the contrary, my objection is to the assumptions which he introduces. The question is: What are the dimensional relations between H and B in space? I confess in all humility that I do not know, and I put $B/H=\mu_0$, a constant of space analogous to the gravitational or dielectric constants of space. Sir James Henderson, however, says, "According to Ampère's theory B and H are physically identical" and apparently expects the scientific world, which has debated the matter for at least sixty years, to take his word for it.

Prof. W. Cramp asks me what justification I have for writing $\mu\equiv 1/A'$ in preference to $\mu\equiv A'$ as suggested by Sir James Henderson. First, Sir James has shown that putting $\mu\equiv A'$ is tantamount to assuming that both are numerics, that is to say, by doing this one is making an assumption which prejudges the very question to which an answer is being sought. Secondly, by putting $\mu\equiv A'$, the force between two current-carrying coils becomes inversely proportional to the permeability of the medium, which, using μ in its generally accepted sense, I do not believe. Thirdly, if as Sir James says, "B and H are physically identical" and $\mu\equiv A'\equiv$a numeric, what has become of the property of space to which Prof. Cramp refers? Surely it has been conjured away, and I feel confident that a little detective work will enable Prof. Cramp to discover at what stage of the performance it was made to vanish.

[1] NATURE, 139, 676 (April 17, 1937).

IN the last paragraph of his letter in NATURE of April 17, Sir James Henderson comes down wholeheartedly on the side of the 'one fluid' theory of magnetism, makes B and H of the same dimensions and, by implication, abolishes μ_0.

I, also, reached this conclusion long ago and in 1924 suggested a form of wording for the definitions of these quantities for insertion in the B.S.I. Glossary which was compatible with this point of view. These definitions raised a storm of criticism at the British Association meeting at Oxford in 1926, with the result that (*a*) the offending definitions were removed from the Glossary; and (*b*) there was formed that British Association Committee on Units over which Sir James Henderson himself presides.

It will be interesting (to me at any rate) to see whether other members of the Committee will follow their chairman's lead; and if they do, whether my definitions will be reinstated and whether μ_0 will be jettisoned once and for all

Statistics of Birth-rate Problems

IN NATURE of April 3, p. 565, a passage is quoted from a recent book of mine in which reference is made to the work of Dr. R. Kuczynski in developing statistical methods of dealing with birth-rate problems. While it is obvious to a reader of the book that I was not making any attempt to give a full account of the development of statistical methods in this field, the mention of one name only in the sentence quoted may seem to imply a neglect of the work of others. Therefore, in order to correct any misapprehensions which the quotation of this sentence may have caused, I should like to direct attention to the earlier work of R. Boeckh and of A. J. Lotka, of which an account will be found in the *Annals of the American Academy of Political and Social Service*, November 1936.

Liverpool.

Points from Foregoing Letters

USING radioactive phosphorus as indicator, a group of investigators from the University of Palermo have determined the relative amounts of inorganic phosphorus (sodium phosphate) taken up by different organs when injected into young rats. Subsequent analysis shows the presence of radioactive organic (lipidic) phosphorus in liver intestine and kidney, in much greater amounts than in muscle or brain. This indicates, according to the authors, that "the participation of the phospholipids . . . results in a complete synthesis starting from inorganic phosphorus".

From observations made in Melbourne on the wave-form of the electromagnetic pulse radiated from lightning flashes (giving rise to atmospherics), Prof. T. H. Laby, F. G. Nicholls, A. F. B. Nickson and Dr. H. C. Webster find evidence of multiple reflections between the earth and an ionized layer at an 'equivalent' height of 78–82 km.

Prof. V. A. Bailey reports observations supporting his theory of the interaction between radio waves Several European stations have collaborated in sending out suitable radiations. Interaction was observed in one case, caused by a gyro-station with a radiated power of only five kilowatts. Comparative tests with London National and London Regional show the existence of resonance in interaction.

Dr. M. S. Vallarta states that the constant intensity of cosmic radiation beyond a certain latitude may be accounted for by a magnetic action of the sun, and that the value of its magnetic moment calculated from the latitude effect leads to a value of the field intensity at the sun's surface in good agreement with that found by Hale and his collaborators. Two observable consequences of this interpretation are discussed.

That certain spectrographic lines and bands of interstellar origin observed by Merrill may be due to the presence of molecules (Na_2, NaK) is suggested by Prof. M. N. Saha. He points out that 'temperature' in interstellar space is near the absolute zero, and that only such states of atoms and ions occur there as have infinitely long life.

G. C. E. B. Hulbert and Prof. C. M. Yonge give reasons for inferring that the function of the osphradium in gastropods is to estimate the amount of sediment carried into the mantle cavity by the water currents created by the lateral cilia on the gills.

Drs. Donald and Alistair Gunn and Miss P. M. Jenkin have collected records which, they state, show that there is no lunar periodicity in human menstruation.

By irradiating (with radium) cells *in vitro* held at a temperature of 6° C., so that active cell life is inhibited, and afterwards allowing the cultures to develop, Prof. L. Halberstädter and L. Doljanski have succeeded in establishing a numerical relation between the amount of growth inhibition and the dose of rays applied.

A number of elements (molybdenum, silver, bromine, antimony, etc.) when bombarded with neutrons are found by F. A. Heyn to give radioactive substances with half-periods corresponding to those obtained when gamma rays are used. This, he points out, is additional evidence that a neutron entering the atomic nucleus may expel two neutrons with the production of a radioactive body.

The absorption spectra, and hence the optical rotatory power, of cobaltammines are, according to Messrs. C. H. Johnson and N. H. Poynton, affected in a specific manner by substitution of ^2H for ^1H in constituent NH_3 or NH_2 radicals. Measurements of optical rotation can thus decide the isotopic composition of a complex ion or of a solvent in equilibrium with it.

Prof. B. C. Guha and J. C. Pal state that alcoholic and ethereal extracts of cabbage give a higher ascorbic acid value on heating in nitrogen, even if the estimation is carried out after mercuric acetate treatment. Further evidence is offered for the existence of combined ascorbic acid in cabbage. The dye-reducing value obtained after heating chloroform extracts of cabbage disappears in large measure by the action of ascorbic acid oxidase, suggesting that the substance produced on heating is ascorbic acid.

Research Items

Bronzes from Iran and Elsewhere

AMONG a number of bronzes from Iran, Iraq and Asia Minor selected because they represent types not hitherto in the British Museum (Bloomsbury), and figured and described by Mr. Sidney Smith in *Brit. Mus. Quarterly*, 11, 2, are a number from Luristan, including an amulet with a suspension ring, which takes the form of a conventionalized 'naked goddess', such as were made in stone and clay at a very early period in Assyria, and similar to a type found in Crete. A small mace-head with bosses is of a type hitherto only known in stone. Each of the bosses is pierced, as if sockets were made to hold studs, but if so it is difficult to conjecture their use. An unusual object is an elaborate holder or *pelle d'offrandes*, of which the form imitates either a wheeled-cart or a sledge, the wheels or runners being replaced by four legs. Three animals stand facing the rear of the cart on an edge some four inches long by ¾ inch broad above the cart, the bottom of which is sunk nearly an inch and is only 2¼ inches long, terminated by an upturned edge ¼ inch inside the termination of the sides. The long shaft—eight inches—which turns in a socket as long as the upper edge, carries two animals facing in different directions, has a ring-attachment which serves as a support, and rises to a yoke, cast separately, the three ends thus made being shaped into unidentifiable animal heads. These bronzes are subject to the doubts about the dates of bronzes from Luristan. A fragment of a concave-sided vessel from Nihawand seems to have been chased over a bitumen ground, as it is not *repoussé*. The faces of the chased figures appear noseless with pointed chins. A harp seems to have eight strings, while a rectangular object is also doubtless a musical instrument and has been identified as an *adapu*, beaten with the hand. A curious object held by a broken seated figure seems to be a misshapen fish. A 'spectacle' amulet from Asia Minor, like others of the same type in ancient times, represented the convolutions of the intestines, and in modern Egypt is a prophylactic against the pains of childbirth.

Zuni Mythology

INTENSIVE study of folk-lore has tended to be neglected for a variety of reasons; but Ruth Benedict points out ("Zuni Mythology". *Columbia University Contributions to Anthropology*, 21, 2 vols.) that Zuni folk-lore affords excellent material for such study, in that a large body of tales has been recorded over a considerable period, indeed more than fifty years, the culture is well known, and in contrast to almost all the other tribes of North America, folk-lore among the Zuni is not moribund. This last-named factor brings out the importance of allowing for variation. In considering the relation of the themes which Zuni folk-lore elaborates in relation to culture, a number of points emerge. No folk-tale is generic. It always relates to a particular people, livelihood, social organization and religion. The final form is dependent on culture. Survivals belong to a dead culture, as in European folk-lore, and the function of myth cannot be studied in such cases. A living folk-lore reflects current use, although there is a lag. Also something must be allowed for idealism and the conventionalization of a Golden Age, which explain the discrepancy between story and fact. A discrepancy of constant occurrence in Zuni folk-lore is the occurrence of polygamy. While all other Indians recognize polygamy and sometimes polyandry, the Zuni are monogamous. This probably represents an element analogous to the fairy element in other systems, the grandiose wish and day dream. Other contrasts are compensatory. For example, the abandonment of children is alien to Zuni culture; and yet it is a popular feature in the folk-tale. This is because the interest centres on the child, and in the story the parents are put to shame. There is no recognition of suicide in Zuni culture, or of taking vengeance on an unfaithful spouse. So in the tale the Apache are summoned, as destruction must overwhelm innocent and guilty alike. An interesting feature is the position of women in sexual matters. The women are regarded as the pursuers; the male is bashful and hangs back.

Episternal Bones in Man

IN 1820, Béclard first directed attention to the occasional presence of episternal bones in man, but they were more fully described eighteen years later by Breschet, to whom subsequent writers have generally given the credit for their discovery. Since then they have been recorded by numerous workers, and a detailed investigation of 2,218 human and 107 anthropoid sterna has enabled W. M. Cobb (*J. Anat.*, 71, Jan. 1937) to review the subject. Ossa suprasternalia were found in 6·8 per cent of 544 adult whites and 2·2 per cent of adult negroes. None was found in the 107 anthropoids. They appear to be homologous with the rudiments of the epicoracoids of the primitive shoulder girdle. The human sternum with a convex manubrial border and ossa sternalia is to be regarded as the most primitive condition, while that with no ossa and a convex border the most advanced. Since all the anthropoids studied were of this latter type, they are in this respect more advanced than human beings.

Mysids and Euphausiids of the Great Barrier Reef

PROF. W. M. TATTERSALL, in his memoir on Mysidacea and Euphausiacea (Great Barrier Reef Expedition 1928–29. Scientific Reports, vol. 5, No. 4; 1936), records seventeen planktonic mysids and six species of bottom forms, and a small collection of euphausiids comprising sixteen species, two of which are larval forms which could not be identified. The occurrence and seasonal distribution of both groups have been discussed in a separate report (vol. 2, No. 8). From these observations it is shown that the night hauls of plankton contain numerous mysids which are scarce during the daytime, and it is probably that they live at the bottom and only become planktonic by night. The new genus *Pseudomysidetes* is created for the new species *P. russelli*, closely related to Mysidetes, and three other species are described as new to science. The euphausiids are specially interesting as they form apparently the first collection made from this locality. Twelve of the fourteen identified species were captured by the *Siboga* Expedition, which operated mainly in the Dutch East Indies, and the remaining two are tropical species which might have been expected in the same area and actually occur in other parts of the Pacific. All are oceanic, except *Pseudeuphausia latifrons* which is a shallow-water coastal form, widely distributed in the Pacific, and this species is the dominant one and is the only form characteristic of the shallow lagoon area inside the reef. A fairly complete series of larval stages enabled the life-history to be followed; this is closely related to that of *Nyctiphanes* and suggests that *Pseudeuphausia* is nearer to *Nyctiphanes* than to *Euphausia*, under which genus it was first described.

Locusts in Malaya

IN a recent bulletin (No. 18, Dept. Agric., Scientific Series, Straits Settlements and Federated Malay States), Messrs. G. H. Corbett and N. C. E. Miller discuss the incidence of two species of locusts in Malaya. As regards the oriental migratory locust (*Locusta migratoria manilensis*) it appears that there is no clear evidence that this insect is indigenous to Malaya. The regular absence of its solitary phase, and the fact that swarms are comparatively infrequent, point to this conclusion. Since Malaya has only been visited twice by swarms of *Locusta* during the past twenty-four years, this fact seems to be due to the distance which swarms have to travel in order to reach that territory. The suggested country of origin is Borneo, and it is considered quite likely that swarms may visit Malaya when outbreaks are in progress in other countries of the Pacific. The second species—the Bombay locust (*Patanga succinta*)—appears to cause negligible damage, but the occurrence of the insect in its solitary phase suggests that it may be indigenous.

Metabolism and Growth-Responses of the Cucumber

MODERN research has not yet made it clear to what extent such growth responses as flowering and fruiting are caused by, or are themselves the cause of, variations in chemical composition of the plant. There is an undoubted relation between the two, and a paper by Dr. R. B. Dearborn (Cornell Univ. Agr. Exp. Sta. Mem. 192, Ithaca, N.Y., July 1936) presents a very detailed contribution to our knowledge in this field. Cucumber plants were grown under conditions of high, and of low, nitrogen supply, whilst the composition of normal bearing plants was compared with that of plants which had their flowers or fruits removed. It was found that fruiting plants had a higher rate of vegetative growth and made more plant material for 10–14 days after pollination, than deflorated plants. Pollination therefore appears to exert a stimulus upon the general growth. The development of fruit had less effect upon the plant when the nitrogen supply was adequate, than when it was low. Amino and amide nitrogen accumulated in deflorated plants, so that the utilization of these fractions is in all probability impeded by the absence of fruit. Carbohydrates accumulated more in low-nitrogen plants than in those with higher nitrogen metabolism. Detailed estimations of the various fractions of carbohydrate and nitrogen are to be found in the paper, and the results show a definite relation between certain of these fractions and the type of growth. They do not, however, determine whether this relation is causal or subjective.

Powdery Mildew of Cucurbitaceæ in Egypt

THE fungus *Erisyphe cichoracearum*, which causes a powdery mildew of melons, cucumbers and other members of the Cucurbitaceæ, is very destructive to these crops in Egypt. Dr. Amin Fikry has published a detailed account of the disease (*Bull.* 175, Tech. and Scientif. Serv., Min. Agric., Egypt, Govt. Press, Bulâq, Cairo, 1936. P.T. 7), particularly with the view of controlling it. Powdery mildew is distributed widely throughout the country, and freely attacks all cucurbitaceous crops except water melon, which may, however, be attacked severely under conditions of high relative humidity. Dusting infected plants with flowers of sulphur was found to be the most satisfactory and practical means of control, though spraying with Burgundy mixture was also effective. A simple apparatus, which applied the sulphur by shaking it through a muslin cloth, was designed, and appeared to be very effective—superior, even, to mechanical dusters. Striking increases of crop followed two applications made when the fungus first appeared, but very little benefit accrued when the sulphur was applied either as a precautionary measure, or when the disease was well established. The bulletin is well illustrated by twenty-four plates, which portray symptoms on different plant hosts, and show various methods of control.

Native Agriculture in Northern Rhodesia

THE Ecological Survey of Northern Rhodesia, which was inaugurated in 1931, was faced with the difficult problem of evolving a quick and sound method of mapping and classifying large areas of country in order to provide a basis for native agricultural development. To have employed a large-scale soil survey would have been both slow and costly. Regional or geographic survey would be unsatisfactory without soil or geological information, which was not available. Vegetation survey, if conducted with due allowance for climatic variation and for changes induced by biotic factors, was found to provide the quickest efficient means of land classification. Mr. Trapnell (*Bull. Misc. Inform., Kew*, 1, 1937), the ecologist of the Survey, describes in detail the method he employed. A direct correlation between vegetation type and native agricultural practice was soon established. The degree of correlation obtained between soil and vegetation type, the reasons for lack of correlation where found, and the type of mapping unit which emerged as desirable for agricultural purposes are explained. The rest of the paper is concerned with agricultural aspects.

Directional Properties in Rolled Brass Strip

AT the annual meeting of the Institute of Metals (March 1937), a paper by Dr. Maurice Cook dealt with a matter of profound importance to producers and users of rolled brass strip. It is shown that the tensile strength of such strip, when the reduction has been sufficient to induce a directional effect, is greatest, and the ductility least, when tested in a direction normal to that of rolling, whilst in the direction of rolling itself the converse obtains. When such cold-rolled strip is annealed, it may still show directional properties which are revealed both by tensile tests and by the occurrence of 'ears' or waves on the edges of cups pressed from such strip. In annealed strip which shows a variation of properties in different directions, the tensile strength is least, and the ductility greatest, when tested at an angle of

45° to the direction of rolling, and it is in this position that the 'ears' are formed. The extent to which 'directionality' exists in rolled and annealed strip is determined largely by the conditions of the penultimate and final annealing treatments and by the degree of the reduction by rolling between them. A study of the orientation of the twinning planes in rolled and annealed 70 : 30 brass strip which shows an appreciable variation of properties in different directions indicates that the frequency of orientation of the twinning planes is least at 45° to the direction of rolling. In the case of strip which does not show directional properties, the twinning planes occur fortuitously in the sample.

Activity Coefficients from Cells with Transference

T. SHEDLOVSKY and D. A. MacInnes (*J. Amer. Chem. Soc.*, 59, 503 ; 1937) have measured the activity coefficients of potassium chloride and calcium chloride by means of potential measurements of cells of the type :

$$\mathrm{Ag}\ ;\ \mathrm{AgCl},\ \mathrm{MCl}(c_1) : \mathrm{MCl}(c_2),\ \mathrm{AgCl}\ ;\ \mathrm{Ag}$$

in which M represents the cation. The calculations involved the transport number t of the cation through the equation

$$-E = 2(RT/F)\int_1^2 t\, \mathrm{d} \log cf,$$

where f is the activity coefficient, for the potassium chloride, and the corresponding equation with the factor $3RT/2F$, instead of $2RT/F$, in the case of calcium chloride. The values of t must be known, and accurate values for the two electrolytes over a range of concentrations have recently been measured by Longswort hand by MacInnes and Dole. It was found that the simple Debye–Hückel equation : $-\log f = \alpha\sqrt{c}/(1+\beta\sqrt{c})$ reproduced the results with great precision over the range of concentrations $0{\cdot}005 - 0{\cdot}2$ for $c_2 (c_1 = 0{\cdot}1)$—the actual measurements extended to $c_2 = 3{\cdot}0$— and $0{\cdot}0018 - 0{\cdot}03$ for calcium chloride (actual measurements up to $c_2 = 0{\cdot}096$; $c_1 = 0{\cdot}05$). The constant β involves the distance of closest approach of the ions, and for potassium chloride and calcium chloride this distance was calculated as 4·1 and 5·2 A., respectively. For higher concentrations, agreement was obtained for the former up to $c_2 = 3$ and for the latter for $c_2 = 0{\cdot}1$, by modified equations obtained by subtracting terms in $c \log c$ and c, respectively, from the simple equation. The results with calcium chloride are of particular interest, since they show that the Debye–Hückel equation in its simplest form applies to the dilute solutions of this unsymmetrical type of electrolyte, the distance of closest approach being sufficiently large to make the higher terms of the La Mer equation negligible.

Estimation of Arsenites, Arsenates, Selenites, and Selenates

IN a communication read before the Czech Academy of Sciences on December 10, 1936, and published in the Academy's *Bulletin International* (1937, p. 1) Prof. J. Milbauer and Dr. J. Vodražka describe a method of estimating arsenites, arsenates, selenites and selenates in mixtures containing all four salts. Molybdic acid serves to detect arsenates in such a mixture, but cannot be used for quantitative estimations since selenium compounds are found to be occluded in the arsenomolybdate precipitate. No such occlusion occurs when arsenates are precipitated as magnesium ammonium arsenate, $MgNH_4AsO_4 . 6H_2O$, on adding ammoniacal magnesium solutions to the mixture. The precipitate is converted into magnesium pyroarsenate, $Mg_2As_2O_7$, and weighed as such. To determine the arsenite a weighed amount of the mixture is oxidized (nitric acid, bromine, sulphuric acid and bromine, potassium chlorate, perchlorate or bromate can be used) to arsenate and the estimation carried out as indicated above. Selenates can be estimated, in absence of chloride, by means of barium perchlorate, which precipitates barium selenate in the presence of perchloric acid. Selenites can then be determined by means of barium perchlorate after suitable oxidation. Should hydrochloric acid or a chloride be present, the total selenium is estimated by reduction with hydrazine sulphate, which yields elementary selenium.

Fuel Briquetting

THE agglomeration of powdery material—especially fuels and ores—is a technical problem of world-wide interest. Its importance is not felt in full measure in Great Britain, favoured as it is by well-distributed supplies of excellent coal. In many countries, fuels are lacking or available supplies consist of low-grade, non-coking or pulverulent material to which the briquetting process is applicable. Accordingly, we find that the technique of briquetting lignite has been highly developed in Central Europe. South Wales has found a Continental market for its anthracite dust in the form of briquettes. In North America the quest of an anthracite-substitute has produced an enormous patent literature. The problem is essentially the production of a suitable binder—preferably smokeless—waterproof, furnishing a briquette which is not only mechanically strong enough for storage and handling before use but also during the process of combustion. The state of the art can be realized from a report on fuel briquetting by R. A. Strong, E. Swartzman and E. J. Burrough issued by the Canadian Bureau of Mines, Ottawa (25 cents, pp. 100). It contains a critical bibliography, and is a welcome contribution to a branch of technology imperfectly supplied with literature.

The Orbit of the Binary Star, Σ 2026

IN *Mon. Not. Roy. Astro. Soc.*, (97, 3, Jan. 1937), Dr. R. v. d. R. Woolley and Mr. L. S. T. Symms contribute a paper in which they describe their method for improving the orbit of this binary, which was discovered by Struve in 1830. Since Comstock published his orbit in 1918, very satisfactory observations have been made, and these have been used to compute an orbit which will probably not be improved for a great many years. The attempt to compute an orbit by Russell's method met with little success, and discordances as large as 15° in position-angle were found when an ephemeris was computed from preliminary curves. Arbitrary alterations were then made in the elements until these discordances were reduced to ± 3·5° in the observed minus computed position-angle, and differential equations were applied to improve the elements of the orbit. A detailed description follows showing the procedure adopted, with the ten places selected as representing the observations satisfactorily. The results show that the period is 680 years, the semi-axis major 3·04″, and the inclination ± 130·6°. It is observed that much of the work in the northern hemisphere which needs to be done on double star orbits is of the nature of improving existing orbits with the use of later observations, and for this purpose the differential method of Innes and van den Bos is well suited.

Mellon Institute of Industrial Research

THE new building of the Mellon Institute of Industrial Research in the University of Pittsburgh was dedicated on May 6, addresses being given by three Nobel laureates, Dr. Irving Langmuir, Dr. H. C. Urey, and Dr. W. P. Murphy. On the following day, a symposium on recent progress in science was held, to which Dr. G. O. Curme, Dr. F. B. Jewett, Sir Frederick Banting and Dr. W. W. G. Maclachlan ontributed.

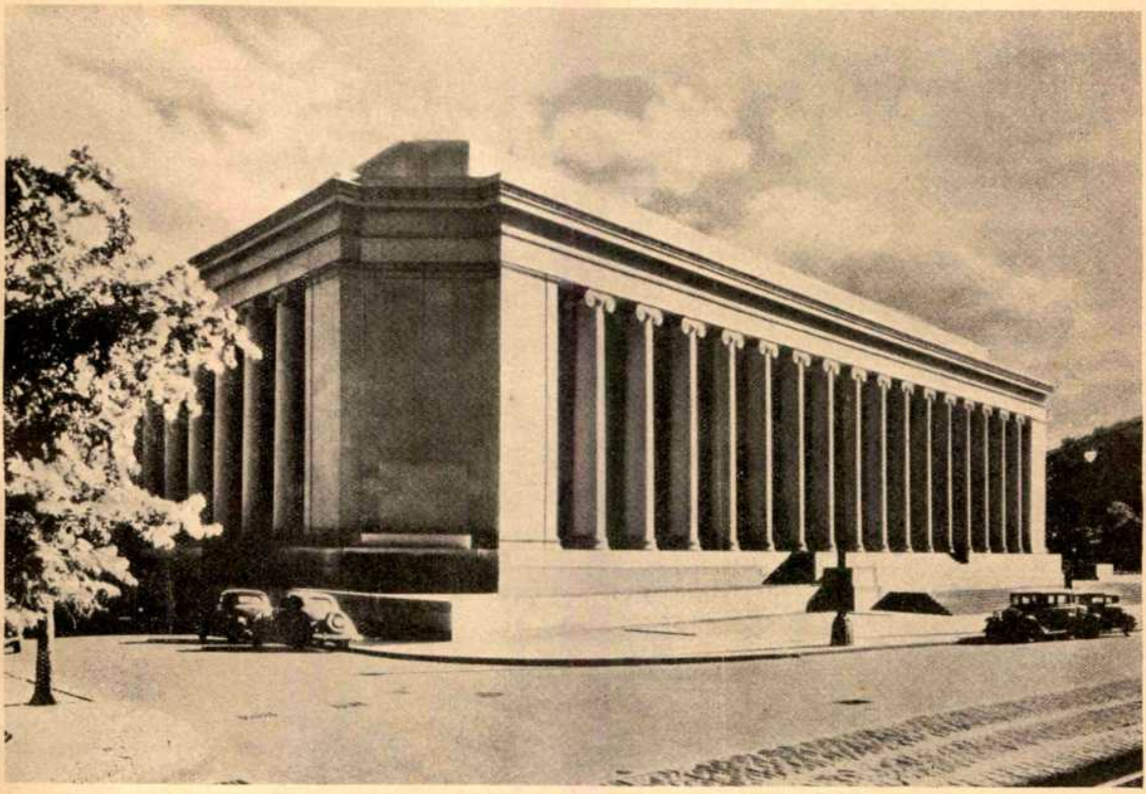

Fig. 1.
NEW BUILDING OF MELLON INSTITUTE, PITTSBURGH, PA.

The new Institute is the gift of the late Richard R. Mellon and his brother Andrew W. Mellon, formerly Secretary of the U.S.A. Treasury. Its origin is to be raced to Prof. Robert Kennedy Duncan's scheme of ndustrial fellowships, under which industrialists co-perate in the prosecution of specific researches. This scheme was first put into operation in 1907 in he University of Kansas and transferred to Pittsurgh in 1911. The Institute under its present name was founded in 1913 by the Mellon Brothers, who uthorized Duncan to design a special building with dequate laboratory facilities. Duncan died prematurely in 1914 and the original building was edicated in the following year, with Dr. Raymond F. Bacon as its first director. He was succeeded in 921 by the present director, Dr. Edward R. Weidlein. An important development, with which Duncan would have been in full sympathy, was the establishment in 1924 of the Department of Research in Pure Chemistry.

Details of the scheme of industrial fellowships having been given from time to time in NATURE (see particularly NATURE, May 23, 1936, p. 855), a summary of the present position and a brief description of the new building will suffice to commemorate the official opening of the largest building in the world dedicated to scientific research. The money appropriated by donors in support of industrial fellowships has amounted in the past twenty-six years to 11,478,406 dollars. In the financial year ending March 1, 1937, appropriations by donors were 816,315 dollars, and 69 fellowships have been in operation, employing 185 scientific workers and engineers. The Institute's contributions to the literature of science include 19 books, 143 bulletins, 744 research reports, and 1,117 papers published in journals; and 669 U.S. patents have been granted. Since 1911, 1,150 fellowships have been established in 275 technological subjects, and 650 processes or products have been invented or developed. In ten instances, new industries have resulted. From 1911 until 1935, no less than 777 scientific workers, having completed the work of their fellowships, have entered the field of manufacture or teaching, and this forms not the least valuable contribution to the promotion of science and industry. In recent years, the Institute has greatly developed its work of a more purely scientific character or bearing on public health. Its investigations on smoke abatement, dental caries, and anti-pneumococcic serum are examples.

With a view to simplicity, beauty and inspiration, the new building was designed in the Greek style (Fig. 1) with a relatively low elevation, three storeys being below ground level. The building has a capacity of 6½ million cubic feet. Its colonnades have a total of sixty-two columns, each shaft—a single block of stone—weighing approximately 60 tons, of which twelve are on the south frontage, sixteen on the east and west and eighteen on the north. At the corners are impressive piers. Models were found in the small temple of Nike Apteros on the Acropolis and in the temple at Sardis in Asia Minor. On three sides a flight of steps leads up to the building. The fifth to eighth floors are devoted entirely to laboratories, most of the space being occupied by the two types of laboratory adopted by the Institute as standard. Doors connecting the laboratories are of aluminium adorned with alchemical symbols.

In accepting in 1935 the Chemical Industry Medal of the Society of Chemical Industry, Dr. Weidlein, the director, said that his task at the Institute had been to assist in infusing science into technology, particularly the chemical industry. This task had two aspects—to convince manufacturing organizations of the functions of scientific research and research management in industry, and to encourage in the public a greater appreciation of the value of science. Thanks to the work of the industrial fellows, the Institute formed a strong link between the world of science and the industries. His concluding words were :

"What about the future ? I believe that all of us at the Institute will have much greater encouragement and opportunities and that we shall be able to do many more useful things when we have the advantage of working in our new building with its splendid facilities for research in pure as well as applied science."

Kew's Contribution to Empire Botany

VISITORS to the Royal Botanic Gardens, Kew, who usually see only the Gardens and Museums, can have little idea of the great role that the Herbarium near the Main Gate has played in the botanical service of the Empire. Since the Herbarium was founded in 1852, members of the staff have, independently and collectively, and in association with other botanists, accomplished a vast amount of floristic work. In order to show the extent of this to the numerous visitors, particularly from overseas, who will no doubt visit the Gardens during the Coronation period, a special exhibit has been arranged in No. 3 Museum. In a large glass case there has been placed a selection of works prepared either wholly by, or with the assistance of, the scientific staff of the Herbarium and Museums.

The general books shown include the classical work of G. Bentham and J. D. Hooker, the "Genera Plantarum", 1862–83, which has been and is still used by botanists in all parts of the world. Next in order is the "Index Kewensis", a work of universal importance compiled at the expense of Charles Darwin, under the direction of Sir J. D. Hooker, by the late B. Daydon Jackson, and continued by various members of the staff. This gives references to the original descriptions of all known species of flowering plants. Alongside is the great index of plant illustrations, the "Index Londinensis", edited by the late O. Stapf. Besides these are the "Hortus Kewensis" of W. Aiton, 1789, which records the species of plants in cultivation at Kew when still a 'royal garden'; the *Botanical Magazine*, the oldest of botanical periodicals, commenced in 1787, and still prepared at Kew, but since 1922 the property of the Royal Horticultural Society; the *Kew Bulletin*, which this year attains its golden jubilee, having been started in 1887; and Hooker's "Icones Plantarum", which last year attained its centenary, and which provides a medium for the illustration of plants of exceptional botanical interest.

The botany of the British Isles is represented by Hooker's "Students' Flora" (1870) and by the "British Flora" of G. Bentham (ed. 1, 1858).

The vegetation of much of China and Tibet is recorded in Forbes and Hemsley's "Index Floræ Sinensis" (1886–1905), Bentham's "Flora Hongkongensis" (1861), and Dunn and Tutcher's "Flora of Hong Kong" (1912).

India has been well catered for by the "Flora of British India", by J. D. Hooker and others (1872–97), and the "Flora of Bombay", by T. Cook (1901–08), the "Flora Simlensis", by Collett and Hemsley (1902), the "Flora of the Upper Gangetic Plain", by J. F. Duthie (1903–29); "Bengal Plants" by D. Prain (1903); and the "Flora of Madras", by J. S. Gamble, completed by C. E. C. Fischer (1915–36). The forestry of India is dealt with in "Indian Trees", by D Brandis (1907), and the "Forest Flora of the Andaman Islands", by C. E. Parkinson (1923).

The "Flora of the Malay Peninsula" (1922–25) was a heavy undertaking by one botanist, H. N. Ridley and the "Enumeration of Siamese Plants" (1925– by the late W. G. Craib, is being continued.

The continent of Australia was early provided fo by G. Bentham's fundamental work, the "Flor Australiensis" (1863–78), and J. D. Hooker's "Flor of Tasmania" (1860), whilst the "New Zealan Flora" (1864–77), by J. D. Hooker, and the "Illustra tions of the New Zealand Flora" (1914) by Cheeseman assisted by W. B. Hemsley, have done much for th botany of that Dominion. J. D. Hooker's "Flor Antarctica" (1847) is a classical work for tha region.

Africa has always taken a first place in the activitie of the Kew Herbarium, and several works of cor siderable magnitude have been issued dealing wit its flora. The "Flora of Tropical Africa" was begun by D. Oliver in 1868, and has been carried on by many botanists, part of the last family, the Gramineæ, commenced by O. Stapf and now being continued by C. E. Hubbard, only remaining to complete the huge task. The work of editing this great undertaking has been carried out by successive directors of Kew, Sir William T. Thiselton-Dyer, Sir David Prain, and Sir Arthur W. Hill, and part of the Euphorbiaceæ was contributed by Sir David Prain.

The "Flora of West Tropical Africa" (1927–36), by J. Hutchinson and J. M. Dalziel, is the first regional illustrated flora of the tropical part of the Continent; its "Economic Appendix" by J. M. Dalziel provides full information on the uses of West African plants. Smaller areas are dealt with in the "Flora of Liberia" (1906), by O. Stapf (in Johnston, "Liberia"); "Trees and Shrubs of Sierra Leone" (1916) by C E. Lane Poole; "Gold Coast Trees and Shrubs" (1913), T. F. Chipp; "Nigerian Trees" (1925), H. V. Lely; "Flora of the Sudan" (1929), A. F. Broun and R. E. Massey, and its companion volume of illustrations by G. M Crowfoot (1929); "Trees of Kenya Colony" (1926), E. Battiscombe; "East African Grasses" (1926–27), by C. E. Hubbard.

The islands of Mauritius and the Seychelles were provided for in J. G. Baker's "Flora" (1877), and latterly the "Seychelles Flora" has been enumerated by V. S. Summerhayes.

The immense task of describing the rich and varied flora of what is now the Union of South Africa, begun by Harvey and Sonder in 1859, the "Flora Capensis", was continued by the Kew staff and others and completed in 1935. As in the case of the "Flora of Tropical Africa", the editorship has been in the hands of successive directors of Kew, Sir David Prain and Sir Arthur Hill also contributing largely to the taxonomic work The "Flora of the Transvaal" (parts 1 and 2, 1926–32), by J. Burtt Davy, is the first of the regional descriptive floras of South Africa. The descriptions for Mrs. E. F. Vallentin's "Illustrations of the Flowering Plants and Ferns of the Falkland Islands" were provided by Mrs. E. M. Cotton.

A. H R. Grisebach's "Flora of the British West Indian Islands" was written in association with Kew; and the "Flora of Trinidad" (1928–), by Williams and Cheesman, is also being prepared in close collaboration with Kew.

Among the general works by individual Kew botanists are the "Synopsis Filicum" (1868), of W. J. Hooker and J. G. Baker; the "Fern Allies" (1887), by J. G. Baker; "British Fungi" (1906), G. Massee; "Diseases of Cultivated Plants and Trees" (1910), G. Massee; and J. Hutchinson's new phylogenetic classification in his "Families of Flowering Plants" (1926; 1935). "Plant Life in the Balkan Peninsula", W. B. Turrill (1929), is an intensive study of a special area.

Researches in sixteenth century botany are represented by the "Herbal of Otto Brunfels", by T. A. Sprague (1928), and the "Herbal of Leonhart Fuchs", by T. A. Sprague and E. Nelmes (1931).

Applied botany is the subject of J. Smith's "Dictionary of Economic Plants" (1882), and his "Domestic Botany" (1871); G. Watt's monumental work, "A Dictionary of the Economic Products of India" (1889–93(6)), and its abridgment, "The Commercial Products of India" (1908); the "Economic Products of the Malay Peninsula" (1935), I. H. Burkill; "Useful Plants of Nigeria" (1908–22), by J. H. Holland; "Tropical Agriculture" (1929), revised by J. H. Holland; "Sorghum" (1936), J. D. Snowden; "Crop Plants of the British Empire" (1936), by H C. Sampson.

Among the more important books on horticulture and forestry are the "Dictionary of Gardening" (1884–88), by G. Nicholson; "The Trees of Great Britain and Ireland", H. J. Elwes and A. Henry 1905–13); "Trees and Shrubs Hardy in the British Isles" (1921), by W. J. Bean; "Rhododendrons" (1930), by J. Hutchinson (Kew), A. Rehder and H. Tagg (published by the Rhododendron Society); "Coniferæ" (1923), by W. Dallimore and A. Bruce Jackson, and the periodical, the *Orchid Review* (1893–), founded and edited for many years by the late R. A. Rolfe. The history of the Gardens is dealt with in "The Royal Botanic Gardens, Kew" (1908), by W. J. Bean.

This list does not include, of course, the numerous smaller papers in scientific journals to which the Kew staff has so largely contributed.

Calculating Machines in Scientific Computing

SCIENTIFIC computing has been materially aided of late years by the development of calculating machines, a development in which scientific workers themselves have had a say. We may instance the use of the modern Brunsviga, with its split register and automatic transfer features, in statistical calculations; the application by Dr. L. J. Comrie of the Brunsviga twin 13z to the Hartmann formula for the reduction of prismatic spectrograms; the use of the Burroughs machine, and later the National Cash Register machine, in the Nautical Almanac Office for finite differencing and integration; the demonstration recently given at Cambridge of the application of the Hollerith rolling-total tabulator for the same purpose, and for general statistical calculations; the machine invented by Mr. R. R. Mallock at Cambridge for solving simultaneous equations; and the Bush machine developed at the Massachusetts Institute of Technology for the numerical solution of differential equations, and since installed by Prof. D. R. Hartree at Manchester.

For some years, the Mathematical Tables Committee of the British Association has concentrated on the production of new tables by means of subtabulation on its "National" machine, a process which has revolutionized the art of table-making; the incidental advantage of having clean type copy produced by the machine for the printer has largely eliminated copying and setting errors. Checking by means of mechanical differencing of tables is equally easy. With regard to the Hollerith, the spectacular production of a table of a polynomial function by feeding the machine with blank cards appealed to many at the Cambridge demonstration, while so far as capacity for work is concerned, it may be mentioned that in a recent agricultural statistical investigation, two Cambridge workers produced a million products in six weeks, that is, at the rate of one product a second

Expensive machines are not readily available to the ordinary scientific worker, and this lends interest to the announcement that Dr. Comrie, formerly superintendent of H.M. Nautical Almanac Office, to whom much of the above mentioned development is due, has set up at 131 Maze Hill, Blackheath, London, S.E.3, a professional "Scientific Computing Service". Dr. Comrie offers his services for (1) scientific calculations generally, and particularly those where mechanical computation and mass production methods may be employed; (2) table-making; (3) purchase and use of calculating machines and mathematical tables; (4) instruction in the art of mechanical computing; (5) press work; and (6) lectures on calculating machines or on computing. He has at his command a variety of machines, including a "National" and Hollerith equipment. As the former is expensive to buy and the latter to hire, here is a means whereby the scientific worker may get computation jobs done efficiently at reasonable rates.

An interesting announcement from Cambridge relates to the proposed establishment of a computing laboratory in the mathematical faculty. The immediate intention is to acquire a Bush integrating machine and the Mallock equation solver, but other machines will be added from time to time, and a wide view is being taken of the service that can be rendered to Cambridge by the establishment of such a laboratory. Besides the applied mathematicians, we can envisage statisticians, economists, biologists, psychologists and others being eager to avail themselves of the specialized equipment that will no doubt be available in time, in order to supplement their existing computational resources. The capital cost of the proposed installation is of the order of £10,000, and it is anticipated that an annual charge of £1,000 per annum will fall to be met by the University, to include maintenance and replacement of machines, and salaries. The scheme has been approved, and the laboratory should be in existence by the opening of the academic year in 1938.

Hybrid Vigour in Plants

INCREASED vigour over either parent of the product of the cross between two inbred lines has been frequently reported in plant breeding and, through vegetative propagation, efforts have been made, especially with trees, to make practical use of the phenomenon. It is usually explained, in Mendelian terminology, as the result of association of several genes for size which had been isolated in either parent, and subsequent loss of vigour in succeeding generations is attributed to segregation. There has been little analysis, however, of the factors contributing to the heterosis or hybrid vigour during the development of the hybrid, so that considerable interest is attached to a recent series of papers by Dr. Eric Ashby, which have brought to light some most unexpected features of this process in specific cases.

In certain strains of maize[1] and in two cases with tomato strains[2] where the hybrid showed greater weight and dry weight, greater height, more leaves and larger leaf area than either parent, analysis of these differences showed no appreciable difference between hybrid and parent in relative rates of growth or of dry weight increase, of rates of production of leaves and new leaf area or of photosynthetic efficiency. Cell size in hybrid and parent also seemed approximately the same, but the embryo of the resting seed seemed larger in all cases.

The only possible conclusion from these results would seem to be that the organization of the growing shoot of the hybrid is upon a larger scale. Embryo and shoot apex form cells more rapidly, but this does not result in a quicker release of leaf primordia from the shoot apex because the whole plan of shoot organization, though still that characteristic of the species, is built upon a larger scale. More cells must accumulate at the apex before the new leaf primordium must separate. Naturally, therefore, when it arises, this primordium is planned on a larger scale from the outset, presumably its procambial and vascular strands are commensurately larger and it grows into a larger leaf, though individual cells, in their metabolic and photosynthetic efficiency, correspond with those of the parent forms.

Dr. Ashby speaks of larger primordia in the seed, but the term is usually applied to leaf primordia, and in the embryo of the tomato, apart from cotyledons, leaf primordia will scarcely be manifest yet. It would seem that the comparison is rather upon the scale of organization of the meristematic aggregate in the hybrid shoot; planned on a more generous scale, it yet maintains the rate of leaf development of the parent, so that its growth must mean a larger number of meristematic cells maintained in full activity at any moment, therefore more cell divisions and the growth organization of the species maintained at its usual *tempo* but on a larger scale.

Dr. Ashby's studies are therefore full of significance in relation to the problem of shoot organization in the higher plant, as well as in connexion with the genetic explanation of hybrid vigour. Dr. Ashby points out that his results are not in accordance with the usual interpretation given to the linkage of genes in the F_1 generation, but there is as yet so little information as to the way in which the gene is geared into the machinery of development that it is early to say whether the conventional explanation in terms of genes can be applied to the machinery now revealed as operating in the development of the hybrid.

Science News a Century Ago

Population of England and Wales

IN a paper read to the Statistical Society on May 15, 1837, entitled "On the Movement of the Populations of England and Sweden throughout seventy-five Years, ending with 1830", Mr. T. R. Edmonds made many observations of interest to statisticians and physiologists. In the course of his remarks, he said that in the majority of European nations the annual births amounted to 1 in 30 and the annual deaths to 1 in 40 of the total population. The highest birth-rate was about 1 in 23 and the lowest about 1 in 33. The highest rate of deaths observed had been 1 in 30, the lowest (in England), 1 in 50 of the population. The highest rate of increase of population observed was in the United States, where the increase for a long period had been at the rate of 32 per cent every ten years. In England, it had been 16 per cent every ten years. In Sweden and England, the proportion of marriages, births and deaths had been progressively diminishing. The annual loss in population in England and Wales through emigration was 4,000 persons in 1820, 9,000 in 1827 and 30,000 in 1832. Part of this loss had been made up by immigrants from Ireland.

The Electrical Society of London

IN *Sturgeon's Annals* (1, 415) is an article directing attention to the Electrical Society of London, which had just been formed, and for which all subscriptions were to commence on May 16, 1837. Members within twenty miles of London were to pay two guineas, members living beyond that distance one guinea. The article was accompanied by a copy of the rules signed by the honorary secretary, Thomas Patrick, of 11 Lowther Arcade, Strand.

"It gives us great pleasure," said the writer of the article, "to learn that Electricity is no longer to be left to the isolated exertions of individuals, or the chance notice of learned societies. . . . The labours of the Astronomer, Geologist and Chemist will now have for their aid a Body ready to pursue with effect and vigour any line of investigation which mutual pursuits may suggest ; and there will thus, we trust, be another of those enobling links of brotherhood, amongst mankind of all nations, drawing still closer the relationship of intellect."

Royal Geographical Society

THE seventh anniversary meeting of the Royal Geographical Society was held on May 16, 1837, Sir John Barrow, the president, being in the chair. In he course of his remarks, Barrow paid tributes to he memory of Horsburgh, Marsden, Murphy and Davidson, whose deaths within the last twelve months had been a great loss to science and the Society ; referred with great satisfaction to the ravels of Captain FitzRoy, Lieut Wellsted, Dr. Andrew Smith, Major Mitchell and Colonel Chesney, nd alluded to the expeditions then in progress nder Back—who was exploring the coasts of North America—Alexander in South Africa and Schomurgh in British Guiana. He also spoke of Grey and ushington who were due to sail in a few days for he coast of Western Australia, "with the hope of eing able to penetrate some distance into the terior of that vast country and set at rest the uestion of the existence, or the contrary, of a great land sea".

The English Medical Profession

AN editorial article in the issue of the *British Annals of Medicine* of May 19, 1837, contains the following remarks : "Besides many excellent anatomists this country possesses in Grant, Sharpey, Owen and others men who imitate the German physiologists and in their lectures take a large survey of the structures and phenomena of the organic kingdom in every stage of their development. Philosophical physiology is growing fashionable. Mr. Owen's lectures—clear, earnest, eloquent, beautifully illustrated—attract almost as many auditors to the theatre of the College of Surgeons as those of Cuvier did to the Garden of Plants in his best days. It is yet humiliating to reflect that England has not taken the initiative in those positive parts of medical science that have been cultivated with most success. In pathological anatomy our Hodgkins and Carswells were preceded by Dupuytren, Laennec, Cruveilhier, Andral and Louis ; in physiology Treviranus, Burdaceh, Muller, Ehrenberg, Purkinje and Valentin had made immortal discoveries or written unrivalled works in the spirit of positive science before the new doctrines found an echo in our schools. . . . The ardent inquirer who wishes to devote himself to scientific investigations cannot count, as in Germany, on an asylum in the Universities ; the endowments and fellowships of Oxford and Cambridge are the prey of rich, indolent men, and he is driven by necessity, as Liebig remarked, to serve Mammon. If a physician, he publishes a book upon new medicines, a treatise upon nervous affections, a book upon the diseases of females, or some other fortune-fraught theme, and is thus seduced, by corrupt institutions, from the path his genius might have illustrated under happier influences."

The Paris to Brussels Railway

IN the *Mechanics' Magazine* of May 20, 1837, it is stated that "The Railway which has long been projected for uniting the capitals of France and Belgium, at length bids fair to be commenced in good earnest. The king of the French has granted to Mr. John Cockerill the celebrated English iron-master of Liège, the 'concession' of the railway for fifty years. The French government is to advance 25 per cent of the cost on the distance from Paris to the Belgian frontier ; and Mr. Cockerill is to be entitled to all tolls and profits for the first half century, when it is presumed, the works will become the property of the nation. . . . The terms of the concession were not agreed to until after the 'high contracting parties' Louis Philippe on one side and Mr. Cockerill on the other had had several interviews. The latter must be allowed to possess a most industrious spirit ; he was a severe sufferer by the revolution in Belgium in 1830 ; and yet it seems is not deterred from adventuring his capital on a soil like that of France, which in fifty years may experience probably half as many revolutions."

John Cockerill (1799–1840) was the son of William Cockerill (1759–1832), the Lancashire mechanic who had worked first in Russia and then in Sweden before settling at Liège. It was John and his brothers Charles and James who founded the famous iron-works at Seraing, of which John became the sole proprietor in 1835.

University Events

Cambridge.—The Adams Prize, offered every two years for an essay on some branch of pure mathematics, astronomy, or other branch of natural philosophy, value £246, has been awarded to Mr. W. V. D. Hodge, Pembroke College. Essays of great distinction were submitted by Mr. T. Groom, St. John's College, Dr. J. A. Todd, Trinity College, and Dr. P. Du Val, Trinity College.

At St. John's College, the following have been elected into fellowships: Dr. A. C. Offord, Keddey Fletcher-Warr Student in mathematics, University of London, 1934–37; F. Smithies, Wrangler and B, Part II, Mathematical Tripos, 1933, Baylis Student, 1934, Rayleigh Prize, 1935, Carnegie Fellow, 1935–37; R. A. Lyttleton, Clare College, Wrangler and B, Part II, Mathematical Tripos, 1933, Tyson Medal for Astronomy, 1933, Procter Fellow at Princeton University, 1935–37.

The Buildings Syndicate recommends that a site be assigned for the new Austin Wing of the Cavendish Laboratory.

C. C. Okell, of St. John's College, has been approved for the degree of Doctor of Science.

At Emmanuel College Dr. R. G. W. Norrish, professor of physical chemistry in the University, has been elected into a professorial fellowship.

It is proposed that a Mathematical Laboratory be constituted as a Department in the Faculty of Mathematics, that the head of the Department be the director of the Mathematical Laboratory, and that Prof. Lennard-Jones be appointed director of this Laboratory.

Proposals are before the University for the addition of metallurgy to the list of subjects which may be taken in Part II of the Natural Sciences Tripos.

Manchester.—The resignation is announced of Prof. W. L. Bragg, since 1919 Langworthy professor of physics, who has built up in the University a school of research well known for its investigations of the solid state of matter. Prof. Bragg has been appointed director of the National Physical Laboratory (see p. 829).

Societies and Academies

Paris

Academy of Sciences (*C.R.*, 204, 1049–1092, April 5).

Charles Achard, Augustin Boutaric and Mlle. Paulette Berthier: Researches on the viscosity of solutions of bile. Viscosity data from three specimens of ox bile in aqueous solutions at concentrations varying from 5 to 100· per cent, and discussion of the results applying the formulæ of Einstein and of Kunitz.

Lucien Malavard: The method of electrical analogies for the calculation of the wall corrections [of wind tunnels].

Etienne Kondor: The Caquot theory of the equilibrium of soils.

Mlle. Marie Bloch: The spectrum of Nova Lacertæ 1936, slightly after the maximum brightness. Comparison of the spectra of Nova Lacertæ and Nova Herculis.

Georges Allard: An expression for the mean electrical density of a complex atom.

Ny Tsi-Zé and Shang Keng-Yi: The vibrations of plates of quartz cut in various planes around the optical axis of the crystal. The relations found by experiment between the angle starting with the Curie section and the frequency are given as curves.

Théodore V. Ionescu: Calculation with the aid of the quantum theory of the energy emitted by an antenna.

René Freymann: The two infra-red (OH) bands of the alcohols and the polyalcohols. molecular associations.

André Michel: The relations between the different solid solutions formed by ferrous sulphide.

Louis Bouchet: The colloidal state caused by various specimens of zinc acting on some natural waters.

Michel Cymboliste: The hardness of electrolytic chromium. The hardness varies with the current density, the temperature and the chromate concentration. Deposits of chromium, with hardness varying between 1,200 and 400 (Brinell), can be obtained at will by varying the above factors.

Maurice Girard: The influence of the replacement of a hydrogen atom in the β position by a methyl group in phenyl-α-oxycrotonic acid.

Paul Chovin: Researches on the Pechmann colouring matters. The synthesis of some colouring matters with unlike substituents.

Vsévolad de Goloubinoff: Differential geochemical prospecting of mineral deposits.

Vladimir Frolow: The analysis of the levels of Lake Ontario.

Frantisek Link: Influence of the season and of the climate on astronomical refraction and the distribution of air masses

André Eichhorn: Nuclear evolution and chromosome enumeration in *Begonia Pictaviensis*.

René Vandendries: New views on the sexuality of the Basidiomycetes.

Pierre Carrère: Some metacercaria of *Atherina mochon*; the experimental development of a Gasterostomid.

Constantin Dawydoff: The Gastrodes of Indo-Chinese waters and some observations on their evolutionary cycle.

Michel Polonovski, Gaston Bizard and Henr Warenbourg: The action of insulin on the muscular glycogenolysis in the dog.

Brussels

Royal Academy (*Bull. Classe Sci.*, 23, No. 1, 1937)

L. Godeaux: Some algebraic hyperspatial surfaces.

T. De Donder and Miss Y. Dupont: New theor of the dynamics of continuous systems (4). Application to elastic bodies.

H. Schots: The square of squares. To form magic square for which all lines, diagonal and ortho gonal, are bimagical, requires 64² elements.

E. Anglade: Certain Laplacian sequences assoc ated with a ruled surface.

R. Godeau: Asymptotic lines and the equatio of Lagrange.

S. De Backer: Viscous fluids and propagab waves.

J. P. Bosquet: Propagation of acoustical energ in perfect fluids.

Geneva

Society of Physics and Natural History of Geneva, February 4.

E. **Briner** and E. **Perrottet**: A method of analysis of very dilute ozone based on the catalytic action exercised by this gas in the oxidation of aldehydes. The method has the advantage that its sensibility increases with the dilution of the ozone.

Aug. **Lombard**: A new sheet of lower Cretaceous at Voirons (Préalpes externes, Haute-Savoie). The author describes a layer of fossiliferous limestones of Hauterivian-Barremian age situated in the Lucinge region at Voirons. This layer is connected with the lower series of sheets of the same age and of the same known facies at Hivernages, connected with the sheet of the external Préalpes. It helps to fix more exactly the limit of the autochthonous molasse of the ultra-Helvetic series drifted in the neighbourhood of Lucinge

Arn. **Pictet** and Melle A. **Ferrero**: A new factor for the agouti coat dissociated in the segregation of an interspecific crossing of guinea pigs. The authors have studied the genetics of the difference of coloration of the coat in a cross between the domestic and wild guinea pig. As the result of crossing, these two species can acquire new types of coat, previously non-existent in them. Moreover, when the same factor exists in the two species, its intensity increases in the descendants.

Arn. **Pictet**: The localization of the factors of heredity in ventral and dorsal areas. The author, after observing a mutation evident in the result of a crossing of wild and domestic albino guinea pigs, has been able to prove that the albino possesses in the latent state all the coloration factors and that it carries the same independent areas of variegation as the non-albinos studied. Hence the albino is a mosaic of dominant variegated areas invisible to the eye and albino areas.

Rome

Royal National Academy of the Lincei (*Atti*, 24, 3–43; 1936).

M. de **Franchis**: Proof of the fundamental theorem on hyper-elliptical surfaces.

G. **Marletta**: Property of the second angle of Green.

B. **Caldonazzo**: Ballast effects due to a couple of sources.

G. **Arrighi**: Oscillations about configurations which have motions of pure permanent rotation.

M. **Airoldi**: *Pelagosite* as a member of a new genus of calcareous alga.

V. **Bambacioni-Mezzetti** and A. **Suardi**: First observations on the importance of cotyledons for the new formation of roots on hypocotyls of *Lupinus albus* L. and of *Vicia villosa* (Roth.).

G. **Goidànich**: Causes of the so-called vernal defoliation of the poplar in northern Italy.

G. **Dragone-Testi**: Germination of the embryos of maize detached from the caryopsis and deprived of the scutellum in presence of polyoses containing fructo-furanose.

H. **Bytinski-Salz**: Development of the tail in Amphibia (1). Experiments on isolation and defects.

E. **Platania**: Nature of the peritrophic membrane f *Reticulitermes lucifugus* Rossi.

(*Atti*, 24, 45–97; 1936).

G. **Rovereto**: Panoramic analysis in the geomorphical description of Liguria.

U. **Cassina**: New graphical construction of the osculatory plane.

G. **Palozzi**: Projective-differential geometry of new lattices of ordinary space.

G. **Bernardini** and D. **Bocciarelli**: Energy and intensity of groups of neutrons emitted by Po + Be (1).

G. **Charrier** and E. **Ghighi**: Oxidation decomposition of 4-phenyl-1, 9-benzanthrone-10 with (1) a solution of chromic anhydride in acetic acid and (2) an alkaline solution of potassium permanganate.

E. **Ghighi**: Decomposition of isodibenzanthrone (isoviolanthrone) by oxidation with an alkaline solution of potassium permanganate.

H. **Bytinski-Salz**: Development of the tail in Amphibia (2). Changes of the correlations between the regions constituting the tail rudiment and the behaviour of the ectoderm of the caudal fin.

V. **Famiani**: Content of vitamin B_1 in grain compared with the international standard for the same vitamin.

A. **Salvatori**: Chlorine content of the albino rat in relation to age.

Vienna

Academy of Sciences, January 28

I. W. **Breitenbach** and H. **Rudorfer**: Heat of polymerization of styrol in solution.

Hans Strouhal: Zoological expedition to the Ionic Isles and the Peloponnesus (18). *Isopoda terrestria*: Armadillidiidæ, Armadillidæ.

Hermann Eichler: (1) New laws of colour indicators. (2) Catalytic synthesis of resazurin.

Werner v. **Koppenfels**: Hypergeometric integral as a period of the quadrilateral representation.

Franz Bukatsch: Influence of the thermal waters of Bad-Gastein on the assimilation of carbon dioxide by different water plants.

February 18.

Erwin Kamptner: Inactive spores of marine coccolites.

Alfred Leimdorfer: Experimental study of the central regulation of the sugar in the blood.

M. **Pestemer** and T. **Langer**: Ultra-violet absorption of binary mixtures of liquids (10). The system benzene-heptane.

Z. **Herrmann** and Ch. **Slonim**: Constituents of the Leclanché cell.

W. J. **Muller** and **Janet Zaph Briggs**: Theory of passivity (31). Passivity of chromium.

W. J. **Muller**: Theory of corrosion (7). Relation between electrode potential, corrosion and corrosion passivity of metals in aqueous solution.

Franz Werner: Data of fourth zoological expedition in the Ægean Archipelago.

Viktor Pietschmann: New local form of *Cobitis tænia* L. (Cyprinoidea), *Cobitis tænia tesselatus*.

Anton Skrabal and **Adolf Berger**: Determination of the dissociation constant of hypochlorous acid by a kinetic method.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Tuesday, May 18

UNIVERSITY COLLEGE, LONDON, at 5.30.—Dr. E. S. Russell: "The History of Physiology: Ancient Biological Conceptions".*

GRESHAM COLLEGE, BASINGHALL ST., LONDON, E.C.2., at 6.—A. R. Hinks, F.R.S.: "Studies of the Solar System" (succeeding lectures on May 19, 20 and 21).*

Thursday, May 20

UNIVERSITY COLLEGE, LONDON, at 5.30.—Dr. Charles Singer: "The History of Physiology: The Emergence of Modern Physiological Doctrines to the End of the 18th Century, with Special Reference to the Growth of Views on the Circulation of the Blood" (succeeding lecture on May 21).*

CHEMICAL SOCIETY, at 8.—Discussion on "Synthesis and Stereochemistry of Condensed Alicyclic Systems" to be opened by Dr. R. P. Linstead.

Friday, May 21

BEDSON CLUB, ARMSTRONG COLLEGE, NEWCASTLE-UPON-TYNE, at 6.30.—Sir John Russell, F.R.S.: "Chemistry in Modern Food Production".

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

TWO EXAMINERS in the Aeronautical Inspection Directorate (Metallic Materials Section, Micrographic Sub-Section)—The Secretary (S.2.d), Air Ministry, Adastral House, Kingsway, W.C.2 (May 17)

ASSISTANT AGRICULTURAL CHEMIST in the Kirton Agricultural Institute and Experimental Station, near Boston, Lincs.—The Principal (May 24).

ASSISTANT LECTURER IN MATHEMATICS in the Brighton Technical College—The Education Officer, 54 Old Steine, Brighton (May 26)

LECTURER IN ENGINEERING in the Plymouth and Devonport Technical College—The Secretary for Education, Cobourg Street, Plymouth (May 29).

LECTURER IN MECHANICAL ENGINEERING in the Rutherford Technical College—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne, 2 (May 29).

ASSISTANT LECTURER IN CHEMISTRY (and Botany or Zoology or Physics) in the Studley Horticultural and Agricultural College for Women—The Secretary (June 7).

ASSISTANT LECTURER IN MECHANICAL ENGINEERING in the Battersea Polytechnic, London, S.W.11—The Principal.

Health and Safety of Industrial Workers

THE centenary of the Factory Act in 1935 led to a good deal of attention being directed to the inadequacy of the Factory and Workshops Act, 1901, which is largely obsolete, and the need for a new Act for the regulation of industry in Great Britain has been widely admitted during the last fifteen years both inside and outside Parliament. More than once, indeed, bills have been introduced; only to be laid on one side in favour of other matters said to be more pressing.

If, however, a new factory act is essential from the point of view of industry, it is, as a recent broadsheet entitled "Industry and Health" recently issued by Political and Economic Planning (P.E.P.) emphasizes, from the point of view of health and safety in industry that it derives its greatest importance, and additional interest is attached to the new Factory Bill in view of the present concern for the physical condition of the nation. Physical culture may be invaluable as a means of maintaining or improving health. It cannot be a remedy for injuries to health which are inflicted by such conditions as bad housing, overcrowding, malnutrition or unhealthy and dangerous conditions of work. The attempt to improve the physical condition of the people means, accordingly, not merely a campaign for physical education, but also a determined and simultaneous attack on all factors undermining the health of the community whether at work or at home.

It has to be recognized in the first place that although, during the nineteenth century, broadly speaking, Great Britain led the world in imposing the observance of minimum standards of safety, health, hours and conditions of employment in factories and workshops, during the twentieth century we have permitted the country to lag behind in these vital matters. Several industrial nations in Europe and in America have surpassed us in the solicitude they show towards their workers. Accordingly, the new Bill cannot be considered only in terms of the improvements it introduces. We must also have regard to the extent to which it remedies the relatively backward state into which our labour code has fallen during the last two or three decades.

Acts of Parliament, moreover, though invaluable for establishing effective minimum standards, and for rounding up laggards, have their limitations as methods of promoting reform. It is impracticable to enforce at any time standards substantially higher than those which the majority of firms adopt or are ready to adopt. The minimum standards prescribed by law may in fact be, and often are, far below those adopted by the more progressive and enlightened industrial units: and the spread of more enlightened methods must to a large extent precede the prohibition of those that are considered unsatisfactory.

It is this fact which makes such legislation of special interest to the scientific worker. While the improvements which the Bill will effect in working conditions will depend largely on the administration, owing to the wide powers given to the Secretary of State in limiting, extending or modifying its provisions, vigilance will be demanded both during and after the passage of the measure to ensure that its intentions are implemented. A large share of responsibility for this vigilance must rest upon scientific workers. Only if they are prepared to make their contribution can we expect the full effect of the new Bill to be realized —securing a genuine advance in the conditions of health and safety not merely within industry but also indirectly in the health of the nation as a whole.

The significance of the contribution of the scientific worker will be best appreciated if we recall first the immense superiority of labour conditions among the progressive firms over the majority, not merely the most backward; a superiority which is largely to be attributed to the more scientific outlook on the part of the managerial staff in such firms. It is further illustrated by the enormously greater incidence of industrial accidents among smaller firms where adequate scientific and technical supervision is lacking, as is shown by the annual reports of H.M. Chief Inspectors of Factories. In fact, the safety provisions of the new Bill are probably its best feature, but their efficacy will largely depend as much upon effective technical supervision and control within industry itself, particularly in the smaller firms, as upon an extension of the factory inspectorate commensurate with its greater responsibilities.

This question of health and safety in industry does not derive its whole interest from the new Factory Bill. The revival of heavy industry, and the re-employment of men who through their unemployment have lost some of their dexterity, make it probable that accident rates will rise even higher than they did last year. The tendency of armament firms under Government pressure to work night shifts and overtime will increase the danger. Moreover, the cost to industry of ill-health, whether due to unsatisfactory conditions such as long hours or poor lighting, or to the nature of the process, is already so high that little further stimulus to improvement should indeed be necessary. It was estimated by the Home Office that in 1934 industry spent nearly £11,000,000 in providing for its liabilities under the Workmen's Compensation Acts. The total number of working weeks lost annually by employees covered by National Health Insurance is estimated at thirty millions, equivalent to an entire year's work of some 600,000 persons. Moreover, any attempt to assess the burden of ill-health to industry must also allow for the losses from labour turnover through unhealthy conditions from inefficiency, due to the same cause among those actually at work.

The vital problem at the moment in industrial health is labour conditions, especially hours of work, the length of which is only restricted by law in four industries, the most important being coal-mining and road transport. In these respects, the Bill falls lamentably short of the recommendations of the report of the Departmental Committee on the Hours of Employment of Young Persons. That this position should be arising eighteen years after the work of the Health of Munition Workers Committee had demonstrated its detrimental effect on industrial output and efficiency indicates an astonishing lack of wise and scientific management. Moreover, it must be remembered that the existence of this position makes it much more difficult for the more enlightened firms to persist in their efforts to shorten the working week and to eliminate overtime. In addition, there is no adequate mechanism for ensuring that the results of research carried out by such bodies as the Industrial Health Research Board are considered and implemented.

When all due allowance is made for the natural time-lag between such research and its application in the improvement of factory conditions in respect of lighting, ventilation, humidity and air conditioning generally, there can be no doubt that the gap is excessive and very seriously detrimental to both industrial efficiency and the health of the workers. The minimum conditions laid down by the 1901 Act are antiquated and sometimes deficient, and although definite standards for different factories have sometimes been worked out, they are only enforced when the Secretary of State is satisfied that any trade is dangerous or unhealthy and where he can therefore issue special orders under the statute. The new Bill does include a clause providing that "sufficient and suitable lighting, whether natural or artificial" shall be maintained in every part of the factory. The new Bill also raises the standard of overcrowding from 250 cubic feet of space per worker to 400 cubic feet and contains general provisions regarding temperature and ventilation, although any standards are to be enforced by legislation. Specific provisions for the removal of dust and for the control of underground workrooms are included. Similarly under welfare there are general provisions regarding first-aid boxes, drinking water, and, in factories employing females, seats must be provided. Provision of washing facilities, rooms for drying clothes, and mess rooms for employees are only compulsory if special orders are made by the Secretary of State.

It is thus evident that the new Bill makes a cautious but definite advance in dealing with the environmental defects and long hours in factories which tend to increase the incidence of diseases occurring in the rest of the community. Unfortunately, the progressive firms which have made a study of environmental conditions still cover only a small percentage of the population.

Similarly, the incidence of industrial accidents is greatest among the smaller firms, despite notable exceptions, and this problem is one that can scarcely be dealt with by legislation alone. Even a very great increase in the inspectorate would be unable by itself to cope with contravention of the law in respect of hours of work of young persons or ensure the strict observance of the new safety provisions. What is needed here is a significant increase in the extent of trained scientific supervision, competent to foresee dangers and to take the necessary precautions in advance and not merely as a sequel to some accident taking toll of life or limb. This is above all a matter for professional associations of scientific workers.

This aspect of the question becomes more important when we consider the relation of the Factory Department to the Home Office, and not to the Ministry of Health, which is concerned with most other medical services of the country. This system has been criticized as anomalous, and obviously close co-operation between the local medical officer of health and the various authorities concerned with the health and conditions of factory workers is extremely desirable. If, however, employees are to be kept in a good state of health, maximum industrial efficiency achieved, and the enormous expense caused by accidents and sickness saved, something much more than the minimum measures enforced by present legislation is required.

The most important need is in fact a considerable expansion of the medical services in industry itself which have already been introduced by a number of firms or industries, sometimes to deal with a particularly industrial hazard or high accident rate. Such services, moreover, are often organized to cover the medical examination of all employees from the point of view of their own health and, as in factories handling food, that of public health generally, and the whole tendency in industry is for this preventive medical service to increase. It is accordingly a disappointing feature of the present Bill that more is not done to make the medical examination of young persons a better protection for them.

It should not be forgotten that the medical services now developing in industry are responsible for an increasing amount of research aimed at the prevention and elimination of industrial hazards. This, of course, is not a matter for the medical officer alone. The chemist, the physicist, the engineer, the works or departmental manager have their own contributions to make, and the problem is one of organizing team work and co-operation in the most effective way. Nor should it be forgotten that questions of professional ethics and responsibility are also involved. The relationship between the general practitioner and the industrial medical officer now being worked out by a subcommittee of the Medico-Political Committee of the British Medical Association is only one aspect of the professional position of the medical officer in industry which equally applies to other types of scientific worker. The clash of loyalties which may quite easily arise is unlikely to be resolved without a definite and accepted ethical code.

The development and improvement of an industrial medical service in fact involves many extremely complex problems, including questions of co-operation between different industrial units. It is believed that unless there is a special occupational hazard, it is uneconomic to employ a full-time medical officer where less than 5,000 persons are employed. Only about one per cent of the industrial population is found in factories of this size, yet smaller factories are confronted with many of the problems which the full-time industrial medical officer has to handle in a large firm. Moreover, there are still firms with high accident rates and specific occupational hazards employing more than 10,000 persons, which have no medical officer on the premises.

The new Factories Bill has accordingly very considerable claims on the interests of scientific workers. Upon their co-operation, both in a technical capacity, and as departmental managers or as members of the inspectorate itself, apart from participation in the considerable volume of research into problems of industrial safety and health still required, the real success of its aims in no small measure depends. Further, the very extent to which they have come to share in the direction and management of industry itself stresses their responsibility for effective and informed criticism of the new Bill, particularly where, as in regard to the provisions relating to the employment of young persons and particularly overtime, it is open to grave abuse and falls lamentably short of standards of enlightened practice of proved desirability.

Malaria in Europe

Malaria in Europe: an Ecological Study. By Dr. L. W. Hackett. (University of London Heath Clark Lectures, 1934, delivered at the London School of Hygiene and Tropical Medicine.) Pp. xvi +336 +22 plates. (London: Oxford University Press, 1937.) 10*s*. 6*d*. net.

IN the Heath Clark Lectures, delivered by the author at the London School of Hygiene and Tropical Medicine in December, 1934, a semi-popular account was given of the most recent developments in malariology. The present volume, published under the terms of the bequest, gives a presentation of material gathered for these lectures. As the author points out, the book is in no sense a text-book on malaria, but a discussion of the newer findings in malaria and the way these are changing our ideas of what endemic malaria is, why it persists, and how it can be attacked. That the title should be "Malaria in Europe" is no surprise to those familiar with recent work on this disease, for there has been no more interesting chapter in the history of malaria research than that which has had to do with the recent unravelling of the malaria problems in Europe.

About ten years ago, the Rockefeller Foundation, in collaboration with the Italian Health Department, founded the Malaria Experimental Station in Rome, where Dr. Hackett and his colleague Prof. Missiroli have done such outstanding work, and soon after, similar centres for field study were created in Greece, Bulgaria and Spain, in all of which activities Dr. Hackett has played a prominent part. The co-operation of Prof. Martini of Hamburg and Prof. Swellengrebel of Amsterdam was obtained for the observation of northern European anophelism and malaria. After preparatory studies, these centres have been engaged in large-scale experiments with every fundamental measure which seems to hold out possibilities of success in combating malaria. As a result of all this work, and of investigations on European malaria by malariologists of many nationalities, there has emerged a very concrete picture of the natural history of malaria in Europe, and of the nature of control measures to be adopted on this continent. Whilst the problems dealt with have been quite special to Europe, it is remarkable that the answers to these problems have had a surprisingly important application to malaria in other parts of the world, and especially to our conceptions of what constitutes a 'carrier species' of anopheles.

The author commences with consideration of the nature of endemic malaria as now understood. The outstanding mystery of endemic malaria in Europe is the way in which it has been steadily disappearing within the last century or more, independently of any conscious effort of man to bring this about. Many reasons have been put forward to explain this, such as better housing, improved economic conditions, and other causes, but it is now realized that this slow recession of malaria from Europe has mainly depended upon causes connected with the natural history of malaria itself. The common European malaria-carrying species, *A. maculipennis*, is not, as formerly thought, a single homogenous species, but consists of some four or five or more sub-species, each of which possesses its own peculiarities in habits and behaviour, peculiarities that, though they might often seem unimportant, have nevertheless in a remarkable manner been responsible for a number of the major epidemiological features of malaria in Europe. An anopheles has the choice perpetually before it of feeding on man or on his cattle. It depends upon the conditions present and the anopheles' own predilections under these conditions how frequently it feeds upon one or the other. A single feed upon man is of no significance, since in order to transmit malaria a second feed must be taken at such time as sporozoites derived from a previous feed have matured. Hence there is a disproportionate effect as regards decrease in transmission if the number of feedings on man is lessened by 'deviation'.

The condition mainly determining the presence of endemic malaria in Europe is agriculture. Primitive agriculture is usually associated with malaria. With rotation of crops, it becomes necessary to maintain cattle to feed on the fodder, and stall-feeding replaces pasture feeding. With 'stabulation', zoophyllic sub-species tend to be deviated, and if these zoophyllic forms alone are present, as is the case over large parts of Europe, malaria disappears, though anopheles are still abundant. This is the explanation also of the 'anophelism without malaria' so constantly seen referred to in the literature on European malaria. To an unknown extent, similar influences must be operating in regard to tropical conditions, and the very numerous species and varieties there occurring.

Much is now being done in various tropical regions on the working out of the habits and relative carrier danger of different species, so-called 'species sanitation' aiming at reducing the more dangerous forms by measures directed against these species through some vulnerable feature in their habits or life-history. In all preventive action the proper "appraisement of the malaria situation" becomes of great importance, and an excellent chapter on this aspect of the case is given. There are chapters also on the part played by the different malaria parasites themselves, and the role of immunity in man in the epidemiology of the disease, also a chapter on treatment in theory and practice, and an extremely interesting section on the strategy of malaria control and various fundamental lines of attack upon the disease.

Very seldom are the facts about disease so pleasantly and easily written about as in this volume, which is quite unique of its kind. Nowhere else will the reader obtain so easily the spirit of modern malaria research in its application to prevention. S. R. C.

The Case for Buchan

Buchan's Days:
a Modern Guide to Weather Wisdom. By E. L. Hawke. Pp. 231. (London: Lovat Dickson and Thompson, Ltd., 1937.) 5*s*. net.

ALEXANDER BUCHAN, secretary of the Scottish Meteorological Society from 1860 until his death in 1907, was esteemed in his lifetime as a worthy man, an able secretary and a tireless investigator. He wrote two excellent books on meteorology, but it is probably true to say that, until a few years ago, his name was almost unknown outside the circle of meteorological devotees. Now, strangely enough, his name is probably the first that would occur to ninety-nine out of a hundred examination candidates who were asked, in a 'general knowledge' paper, to state the name of a distinguished meteorologist, dead or alive.

Buchan's posthumous fame has been acquired as a result of his researches on the irregularities in the annual march of temperature, as revealed by daily averages of temperature at certain Scottish stations. When such daily averages are plotted, it is found that the resulting graph differs very materially from a smooth curve. The temperature does not rise steadily from a minimum in winter to a maximum in summer and then fall steadily again to the winter minimum. On the contrary, a series of humps and hollows is found, indicating that a steady rise or fall is not, on the average, maintained for more than a few days at a time. Buchan satisfied himself that certain of these humps and hollows were due to a tendency for spells of relatively warm or cold weather to recur around definite dates. Buchan's "warm periods" and "cold periods" have thus kept alive the name of the worthy Scottish meteorologist.

Since Buchan's death, there has been much controversy as to whether these "periods" are a real and permanent climatic feature of our area. Participants in the controversy have not always taken the trouble to refer to Buchan's original papers; consequently, much of what has been written is irrelevant to the issue. Mr. E. L. Hawke has done a useful service in giving a fair and clear summary of the original papers. His commentary upon the papers is not very likely, however, to win over many adherents to what we may call the 'Buchan doctrine'. He directs our attention to the resounding "successes" scored, for example, in the famous frosts of February 1917 and February 1929, and to the support given in certain cases by the Greenwich daily averages. But that sort of evidence does not really get us any further. Everyone knows that our weather tends to occur in 'spells'. The essence of the Buchan doctrine is that cold spells and warm spells tend to occur around certain specified dates rather than on other dates. Well then, let us take the best temperature record we can get, start with January 1 and see how often the temperature on that date has been, say, ten degrees or more above normal, and how often it has been ten degrees or more below normal (the 'normal' being the value indicated by an idealized smooth curve drawn through the monthly means). Do this for every day of the year. The job will take some time, but we shall be rewarded in the end with a set of figures from which we can say with reasonable certainty whether or no there is any special tendency towards abnormality during Buchan's periods or during any other periods. The adherents of Buchan seem strangely reluctant to use this very simple and obvious method of establishing their case.

Part 1 of Mr. Hawke's book is devoted to Buchan, with a very interesting, but not very relevant, chapter on "Weather Lore". Part 2, entitled "Round the Year", contains a series of chapters on the general climatic features of the months and seasons. These chapters are very good of their kind, and contain much curious information such as: "on May 18, 1891, a heavy drifting snowstorm over many hundreds of square miles in England gave holiday-makers the only recorded opportunity for tobogganing on Whit Monday". E. G. B.

The Medical Officer of Health in Present-day Germany

Der Amtsarzt:
ein Nachschlagewerk für Medizinal- und Verwaltungsbeamte. Bearbeitet von Dr. A. Gütt, Dr. L. Conti, Dr. W. Klein, Dr. O. Schwéers, Dr. Th Sütterlin Prof. Dr. R. Thiele, Prof. Dr. F. Wiethold. Pp. xx+767. 22 gold marks. Deckblätter zu der Amtsarzt. Erste Folge. Abgeschlossen am 1.8.1936. Pp. 35. 3 gold marks. (Jena: Gustav Fischer, 1936.)

THIS book, intended as a work of reference for the use of medical officers of health and officials working in administrative capacities related to medicine in present-day Germany, is of a character entirely different from the usual medical text-book or work of reference. Although it represents a source of information on public health, hygiene, medical jurisprudence, social and State medicine and their legal aspects in particular, there can be little doubt that it is intended to convey instruction conforming to the National Socialist point of view. In this way a definite attempt is made to imbue medical activity with unilateral political ideas and force party views upon it. There are several articles exclusively devoted to political and party matters; this is not in any way concealed and cannot therefore be left out of account. There are, of course, chapters on subjects such as bacteriology, chemistry, pharmacology, pathology, psychiatry, etc., in conformity with universal scientific opinion. It need scarcely be mentioned also that in a country where social services have long been so widespread, these have been continued, varied and in some cases added to under the new regime.

The National Socialist party, through its State organs, controls every activity connected with the subject of public health, commencing with medical students and including nurses, masseurs, disinfectors, social workers, etc., by State examinations. Admission to the universities, hospitals and training schools is dependent on the so-called 'Aryan' descent, nationalist reliability and sometimes even party information. Lay treatment is permitted, except for ailments of the sexual organs and vaccination. Lay practitioners must not be called 'quacks' if they are members of the union of lay practitioners in Munich. The same snatching at popularity is shown in the endeavour to raise the standard of the midwives at the expense of the medical practitioners. A midwife is allowed to deliver even breech cases or the adherent placenta without calling in a medical man; in certain districts she is not only permitted but bound to carry out, when required, internal version of the fœtus. The two latter occurrences have to be notified to the medical officer of health. "The demand to transfer more or less all maternity cases to maternity homes is not justifiable from the point of view of social hygiene as the results of cases delivered at home are at least not bad. Moreover, the participation of the whole family in the trying hours of entrance into motherhood strengthens family feeling and family ties so much that it must on no account be forgone"

The infant welfare movement is blamed for "having in some places overstepped the limits prescribed for social welfare work and thus acting, if not rightly supervised, against natural selection". The most important and promising suggestion of the writer of this chapter is to divert child welfare endeavours from the prevention of death amongst infants, at present the predominant activity, towards creating new life by greater fertility and by fighting against a decreasing birth-rate. In another place (marriage laws) it is pointed out that diminution of unemployment cannot be expected by a married couple of which one partner is incapable of procreation. Their marriage is therefore against the interest of the community, because children, as they are only consumers and not competitors in the labour market, play a special part in political economy.

It is impossible to discuss in detail the regulations on health certificates for couples intending to marry or those dealing with the possible prohibition of marriage; or to deal with the advisory centres on questions of heredity, race and marriage. The laws for prevention of an offspring likely to be tainted with a hereditary disease are too detailed for discussion here, but we may note that compulsory sterilization is provided for this purpose, and also interruption of pregnancy up to the end of the sixth month is permitted by law. Compulsory castration can, and in the commentator's opinion, "has to be carried out unhampered by liberalistic sentimentality" in the case of second offences of most sexual crimes including homosexuality, for which the offender is sent to prison for a term of at least six months. Voluntary castration is permitted to those who without a previous trial or conviction profess to feel a propensity for one of the above-named vices. The medical officer of health has to decide whether "further lapses are to be feared".

As in the chapter on infant welfare, no mention is made of the fact that morbidity and physical weakness are not infrequently due to an avoidable or remediable neglect of acute conditions, only of a temporary nature and easily overcome in a few years. On the subject of procreation and marriage, heredity and race, the same pessimistic and fatalistic crudity is displayed. Almost every physical, mental, psychic quality of man seems to be inherited and unalterable, practically none produced or aggravated by economic, environmental or other conditions of life. No notice is taken of the fact that not a few manifestations of neurotic persons mentioned in the list of indications for the most cruel interferences with their lives are not hereditary and are curable, or at least improvable to such an extent as to make the disability from which they are suffering negligible to the community.

The chapters dealing with eugenics, racial hygiene and measures tending to the "gradual purification and improvement of the hereditary stream of our people" abandon in many respects the scientific basis of causation and replace it by the nebulous mysticism of the Nazi creed and empty catchwords. The profession of medicine, which is justly proud of, and continually aims at, scientific fundamentals and independent objectivity, is thus degraded to a state of servitude to the views of the prevailing political party, in which the medical officer of health is the expert party representative.

The addenda are in conformity with the general trend of the book. X. Y. Z.

Agricultural Chemistry

A Practical Course in Agricultural Chemistry: for Senior Students of Agriculture, Dairying, Horticulture and Poultry Husbandry. By Frank Knowles and Dr. J. Elphin Watkin. Pp. ix+188. (London: Macmillan and Co., Ltd., 1937.) 10*s*. net.

FORMERLY agricultural chemistry was one of three main subjects in courses on agriculture, but to-day increasing specialization inside the industry itself has been accompanied by a multiplication in the courses available in the university departments and colleges engaged in agricultural education. A student may present himself for a course in horticulture, or dairying, or poultry-keeping, or in agriculture; he may be an intending producer, technician, adviser, teacher, or specialist; but in any event a goodly proportion of his time will be spent on agricultural chemistry. For most students, the materials and vital processes concerned are the same, but the emphasis on them varies according to the type of specialization desired or the nature of the qualification sought.

The authors have had this diverse field in mind, in their effort to provide what has hitherto been lacking, a laboratory text-book which would adequately serve all types of senior student. So far as methods of estimation are concerned the result is to be commended, but while laboratory estimations are a valuable help to a student, they are less effective if unaccompanied by, or based on, qualitative work, an aspect which seems to have been lost sight of in some chapters. On this account, and because of the impracticability of elaborate technique in ordinary classes, the book may prove less helpful to beginners than to advanced students.

In the field, soil is studied as a natural object, but in the laboratory it becomes and is treated as a dead material. Before it is 'prepared' for analysis, however, much can be learned by close examination, by hand and eye. The main constituents of soil are worth similar attention, but the chapter on soils neglects this aspect of the subject. The order of presentation of the determinations seems to lack purpose, such as is obvious where mechanical analysis leads up to physical properties, and chemical analysis is followed by base status and availability of nutrients.

In the chapter on fertilizers, a few exercises are introduced to illustrate manufacturing processes; but the need of the student to grasp their simple physical and chemical properties is ignored. It is to be regretted that farmyard manure is considered mainly on an N.P.K. basis.

By contrast, the chapter on biochemistry is based on qualitative work, and the whole field of materials—except flesh—is explored by informative exercises in isolating the chief constituents. The methods of analysis for feeding stuffs include some associated with special features of individual commodities, but this section is not set out in such a way as to strengthen the student's knowledge of feeding stuffs as a whole, as distinct from his ability to analyse them. The excellent chapter on dairy products includes material which has not hitherto appeared in a student's text-book.

The section on water analysis contains methods of estimation alone, but that on insecticides and fungicides, an innovation in this class of book, contains in addition informative exercises on their composition and important properties.

The book as a whole is compact, comprehensive, and clearly written, and should be found of use to all classes of agricultural students. H. H. N.

The Physics and Chemistry of Paintings

Three Lectures given before the Royal Society of Arts, March 1937. By F. Ian G. Rawlins. Pp. 52. (London: Royal Society of Arts, 1937.) 2*s*. 6*d*.

THESE three lectures by Mr. F. Ian G. Rawlins are not only of the greatest interest to those who have specialized on the materials and methods used in painting pictures in the past, but are also epoch-making in that they mark a departure in the whole conception of their duties on the part of those responsible for the preservation of the priceless works of art contained in our public galleries.

The first realization of the part to be played in the systematic scientific examination of works of art we owe to Prof. Forbes, of the Fogg Museum, Harvard University, who opened a laboratory for the study of these questions. This was followed by the creation of a scientific department in the Louvre, and the establishment of laboratories in the British Museum under the able guidance of Dr. A. Scott, and to-day we have the laboratories at the Courtauld Institute under Mr. Daniel Thompson, and the appointment of Mr. Rawlins on the staff of the National Gallery.

In the opening lecture, Mr. Rawlins discussed the general problems and the physical and chemical properties of the materials out of which a picture is built up. In the second lecture he discussed the 'diseases' of pictures, and the experiments undertaken at the National Gallery for the systematic collection and examination of dust, and the microscopic examination of the surface of pictures through the Ultropak microscope fitted with crossed nicols to exclude reflection, and the uses of ultra-violet light in examining pictures. The concluding lecture was devoted principally to the use of X-rays, the description of the special apparatus at the National Gallery and the methods used to systematize and control results. He also described a very interesting new feature, the use of the Lovibond tintometer to measure the colour values of the surface of pictures and record the results of cleaning.

Mr. Rawlins touched on so many problems in the course of his lectures and suggested so many possible lines of inquiry that it is impossible to deal with them in a short notice, but he may be congratulated on having given a series of lectures which will be much appreciated by all students of this subject and form a valuable contribution to our knowledge.

A. P. LAURIE.

Einfuhrung in die Elektrizitätslehre

Von Prof. Dr. R. W. Pohl. Vierte, grossenteils neu verfasste Auflage. Pp. viii+268. (Berlin: Julius Springer, 1935.) 13.80 gold marks.

THE first German edition and the English translation of the second German edition of this book have already been noticed in this journal. The present fourth German edition, much of which has been entirely rewritten and brought up to date, will certainly not fail to have the same appeal as its predecessors.

The book makes interesting reading on account of its original method of presentation. The author starts at once with crude conceptions of 'volt' and 'ampere' in the same way as text-books on mechanics start with 'kilograms' and 'seconds'. Well selected experiments—nearly every one of which is illustrated—serve to refine gradually these conceptions. Thus the modern theory of electricity and magnetism is developed in a clear-cut way. A presentation of this type forms not only a good introduction, but also it certainly helps to clarify the ideas of students who have approached the same subject on more conservative lines.

In the new edition the addition of two very clear chapters on "Matter in the Electric Field" and "Matter in the Magnetic Field" have to be specially welcomed. To avoid enlargement of the book the author has shortened the text in some other places, not, however, always to the best advantage. These shortcomings—they are very few indeed—will not trouble the type of reader who will consult the book in Great Britain, and if we are provided with a new English translation they may be easily remedied.

A. B.

Biology in the School

By H. Alan Peacock. Pp. xvi+354. (London: William Heinemann, Ltd., 1937.) 10*s*. 6*d*. net.

AMONG the ever-growing list of books on the teaching of the biological sciences, the present work will find an honourable place. It is the result of many years of experience on the part of a public school science master. The book is intended as a volume of reference, and as such it is admirable. The spirit is eclectic, and Mr. Peacock suggests many lines along which secondary school work in biology may be undertaken and he avoids the pitfall of the rigid syllabus and method of treatment. "The ideal syllabus has not been constructed and when it has been, much of the infinite joy of learning and of teaching biology will have gone. Biology should be introduced into schools not only because of a practical value equal to, or greater than, that of the other sciences, but also because of its cultural value and the national necessity of thinking biologically."

All the book is useful, but particularly valuable are the sections on the library and the comprehensive book list both for scholars and teachers. The many external and human factors governing a choice of syllabus are dealt with admirably and there are numerous hints on the special technique of teaching the biological sciences—a technique which is still being developed. The foreword has been written by Sir John Russell.

W. L. S.

Science fights Death

By D. Stark Murray. (Changing World Library.) Pp. x+149. (London: Watts and Co., 1936.) 2*s*. 6*d*. net.

THIS book tells briefly and simply what medicine is doing to advance our knowledge of disease. It deals with macroscopic parasites, with bacteria and with viruses, with hormones, industrial diseases, cancer and anæmia. It can be recommended to the layman as a trustworthy and readable sketch.

Recent Crystallography*

By Sir William Bragg, O.M., K.B.E., P.R.S.

BENEATH the immense variety of Nature's structures lie certain remarkable simplicities. Thus the elements used in the building are surprisingly few in number. There are but ninety-two in all, of which only a few are of common occurrence, and many are used very sparingly. Indeed there are one or two of which it can only be said that they should exist, though as yet they have not been found. Oxygen constitutes half of the known world, half the remainder is silicon; aluminium comes next. In living things carbon is one of the most important elements, yet it constitutes only a fraction of one per cent of the world as a whole.

It is becoming clear that Nature is most economical in her designs also. This very remarkable phenomenon is especially evident in the structures of living matter. The proteins which play such a predominant part in the animal are all based upon a certain fundamental pattern, and so is the cellulose which plays a corresponding part in plant-life. The recent discoveries of the biochemists have revealed the existence of several classes of substances, as for example the sterols, which though minute in amount have a powerful effect on life and health. In each class a basic pattern is common to all, and the rich variety is derived from a common theme.

There is a further simplicity in the regularity of arrangement of the atoms and molecules in all substances, or at least in the effort to achieve regularity. It is naturally most in evidence in the solid body. When the solid forms from the melt, or assembles out of solution, or grows from deposited vapour, the atoms and molecules of which it is made settle themselves in orderly array. The process is often sensitive to disturbance of the surrounding conditions, but if it is allowed to go on as it begins, it ends in the production of a visible crystal. The constancy of the angles which the faces of a crystal make with one another is evidence of the regular repetition in space of some fundamental collection which is the unit of pattern of the whole. Crystallographers have long surmised that the crystal is the consequence of such a construction.

The X-ray methods of analysis have made it possible to observe and measure these regular details of the assembly. The methods have often been described; it is sufficient to say now that they depend on the reactions between the fine and regular succession of the X-ray waves and the fine regularity of the crystalline arrangement, the two degrees of fineness being fortunately of the same order. The study of crystalline matter with the help of X-rays is one of the most powerful methods of investigating natural structures. It has contributed materially to the realization of the fundamental simplicities in the choice of design.

When the X-ray methods were introduced, they were first applied to the determination of the simpler crystalline structures—rock salt, diamond and the like. Since then the improvements in technique and in theory have been so great that complicated structures have been completely worked out, such as for example the silicates and some of the less complex organic crystals; and it has been possible to go some way in the examination of the complicated and large molecules which are found in living organisms, such as the proteins to which reference has already been made.

The first of the proteins to be examined in detail was 'keratin', the important constituent of wool, hair and horn. It is a remarkable illustration of the persistent occurrence of regularity in the structures of Nature, and at the same time of the power of X-rays to discover it, that crystalline structure should have been proved to be an important feature of substances which are ordinarily supposed to be anything but crystalline.

The fundamental feature of keratin is the constant repetition in a zigzag line of the atoms carbon, carbon, nitrogen in long succession. The same repetition is found in all the proteins. These atoms carry certain attachments, some of them invariable, others not. In the protein chain when extended to its full length, each nitrogen carries a hydrogen atom, and one of the two carbons in each unit carries an oxygen to which it is joined by a double bond. The other carbon carries a hydrogen, and is also attached by a single bond to one end of a secondary or side chain, which varies from protein to protein, and generally from portion to portion of the same protein. In the accompanying diagram (Fig. 1), taken from Astbury's "Fundamentals of Fibre Structure", the side chains are denoted by R, R, . . . The difference between one protein and another, so far as constitution is concerned, is due to differences in the nature of the side chains.

By X-ray measurements it has been possible to determine the length of the repeat in various forms of keratin, and to show its constancy, and its agreement with the suggested structure and with the values of interatomic distances as found in other organic crystals.

---

* Friday evening discourse delivered at the Royal Institution on January 29.

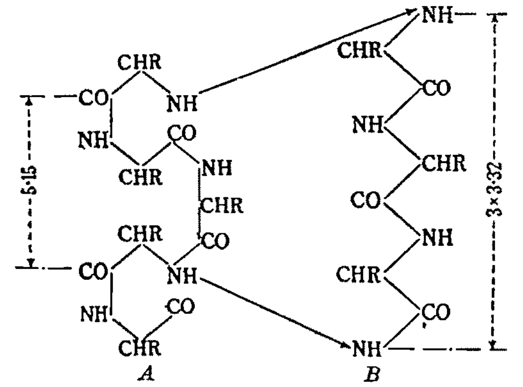

Fig. 1.

A. A keratin chain partly coiled up. Notice the approximation at certain points of the NH and the CO. *B*. The extended keratin chain. (Astbury.)

Svedberg showed in 1929 that by means of the greatly accelerated settling of a suspension subjected to centrifugal force, it was possible to estimate the weights of various proteins. He found that nearly all those which he examined had a molecular weight of about 35,000, or a simple multiple of this number. In blood he found certain others of still greater molecular weights, to be counted in millions. The constitution of all proteins is about the same, that is to say, carbon 50–55 per cent, hydrogen about 7 per cent, nitrogen 15–19 per cent, oxygen 19–24 per cent, with traces of sulphur, phosphorus and metals. In keratin the sulphur content may amount to 2 or 3 per cent.

Proteins are assembled in the course of plant life. Animals require proteins for their nourishment, but do not themselves manufacture them to any considerable extent. They must therefore eat plants, or eat animals that eat plants. Emil Fischer showed, at the beginning of this century, that the assemblage of a protein was accomplished by the successive linking of amino-acids into a long chain, water molecules being shed in the process. The amino-acids are long-chain molecules, at one end of which (and sometimes at both ends) are found the basic group NH_2 and the acid group COOH. The linkage is effected by the interaction of the basic group of one amino-acid with the acid group of the next as illustrated in Fig. 2.

It is an accepted hypothesis that two parts of a molecule, separated from each other by a single bond, can be rotated with respect to each other about that bond. The long chain illustrated in Fig. 1*B* can therefore be crumpled up into less extended forms by successive rotations about its bonds. Astbury supposes that the keratin chains of a wool fibre in its unstretched state are shortened into the form of Fig. 1*A*. It is interesting to observe that a nitrogen is now brought near a carbon which is five links away along the chain (Fig. 1*B*). Frank has pointed out that a junction must be effected here between the N and the C; the H belonging to the N passes over to the C=O group, converting it into C—O—H. Groups of hexagonal rings are thus formed.

The side chains of one long-chain molecule can interact with the side chains of another, and it is in this way that the long molecules are tied together into a firm substance like hair or horn. When the chain is coiled up, these side chain attractions are more and more satisfied by interactions in the molecule itself. It is possible that in this way, as has been particularly emphasized by Wrinch[1], something like a ball is formed, which has relatively little attraction for other similar balls. Such may be the case in the white of an egg in its natural state; boiling the egg breaks up the balls, and the uncoiling chains link together, forming the solid mass of the white in a boiled egg. The substance is said to be 'denatured'.

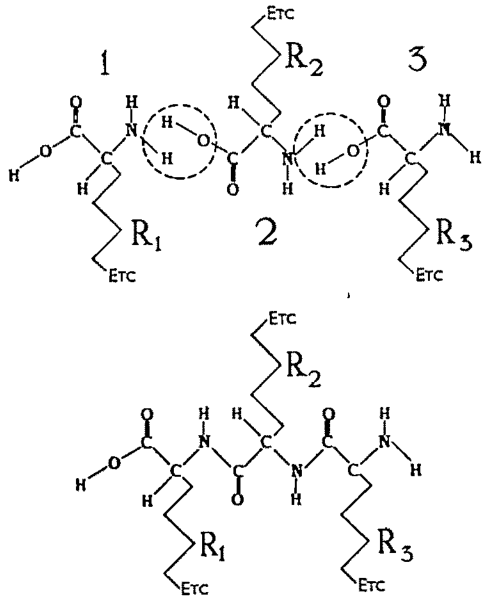

Fig. 2.

In the upper portion of this figure three amino-acid molecules are drawn side by side, as if they were ready to be linked together. In the lower portion the junctions have been made: with the shedding of water molecules formed by the combinations of the atoms within the circles of the upper portion. The side chains R may vary in form. If they are, alternately, a single hydrogen atom and a methyl group (CH_3), the particular protein is the constituent of natural silk.

(*To be continued.*)

Wood-pulp and the Future

IT is safe to state that during no similar period since the first commercial production of wood-pulp in the middle of the last century has our knowledge of the subject advanced so rapidly as during the past three years. A number of entirely different influences have contributed to this activity. In the first place, one of the benefits associated with slump conditions is the time (and in the case of far-seeing concerns, the stimulation) it provides for research work; and secondly, there has been an increasing demand for rags for paper-making, which has resulted in a shortage, and consequently, rising prices in this market. To this may be added the growing use of certain classes of wood-pulp for rayon manufacture, the present position being that this industry now absorbs ten per cent of the world production of wood-pulp; in some quarters there is even a scare of a shortage of pulp for paper-making in the future.

These various influences are all apparent in the advances referred to. Prolonged research has for example resulted in the production of 'alpha-pulps', so named because they contain a high proportion (90–98 per cent) of α-cellulose; this is the name given to the constituent which is insoluble in a 17·5 per cent solution of sodium hydroxide at 20° C. under specified conditions. The method of production is usually a modified sulphite 'cook', followed by chlorination, extraction with alkali and careful washing.

In comparison with ordinary wood-pulps, alpha-pulps have some interesting properties. In the first place, highly absorbent papers may be made from them, and they are therefore very suitable for the manufacture of paper towels and handkerchiefs for facial tissues, etc., the use of which is far more common in the United States than in Great Britain. Papers made from such pulps also lend themselves readily to impregnation with rubber latex and similar materials, and as a result of subsequent processing they can then be converted into leather substitute[1]. There is already a wide market for products of this kind in the manufacture of handbags, fancy goods, bookbindings, shoe linings, etc. where effect is more important than durability. Furthermore, since alpha-cellulose represents the nearest approach to true cellulose obtainable on the manufacturing scale, it is not surprising that advantage has been taken of the inherent strength of the fibre to use it in the production of certain classes of strong papers. Special mention may be made of papers the tearing-strength of which is important, because in such cases fibre length is of special significance. The use of alpha-pulps in this connexion, however, calls for special care, because alpha-pulps do not respond in the same way as other wood-pulps to the development of strength characteristics by 'beating'. Moreover, as resistance to tear is obtained only by sacrificing other forms of strength, for example, bursting-strength, it is usual to add only a relatively small proportion of the alpha-pulp, and, so far as possible, to beat it separately.

Recent work has shown[2] that the permanence of paper, that is, its resistance to the effects of normal ageing, depends as much on the purity of the cellulose present as on the origin of the fibre, and although the traditional preference for rag is still strong, it is now recognized that a paper made from a carefully prepared wood-pulp can last longer than an inferior rag paper. The difficulty of devising a really reliable accelerated-ageing test is probably the biggest obstacle to the demonstration of the relative merits of these fibres. Apart from these questions, however, the fact that the alpha and similar pulps contain such a high proportion of α-cellulose is an obvious argument in favour of their use in 'permanent' papers. This course has so far been justified by such accelerated-ageing tests as exist; provision, however, has also been made for natural ageing tests, the conclusion of which must be left in the hands of the next generation.

Since the method of preparing alpha-pulps is similar to that employed for the determination of α-cellulose (cf. *supra*), namely, removal of other substances by selective solution in various reagents such as sodium hydroxide, it follows that the yields of pure material are necessarily low. This and the manufacturing costs arising from the use of several treatment processes have made these pulps rather expensive, and would seem to be the factor which at present places a limit to their more extended use.

The advances in the technique of bleaching wood-pulps which have been a feature of recent years have also resulted in the production of some interesting types of pulp. These are based on the treatment of the pulp with the bleaching agents in several stages instead of in one only. Chlorine, either as gas or in the form of an emulsion in water, is used in the first stage. This procedure serves to chlorinate the lignins and other undesirable substances in the raw wood, the resulting compounds being soluble in alkali; removal of these in this way is therefore the second stage. Up to this point, there is no real improvement in the colour of the pulp, but the bleaching proper may now be carried out, hypochlorite being the reagent used. This again may be operated in one, two, or even three stages. It is interesting to note that the use of chlorination for the isolation of cellulose was proposed by Cross and Bevan[3] so long ago as 1903, but it is only within recent years that advances in chemical engineering have enabled the process to be realized in practice.

The principal advantage of this method of bleaching is that the colour may be improved without undue detriment to strength, but the elimination of a good deal of the dirt and troublesome resinous matters in wood and an economy in bleaching costs are further benefits which are not to be ignored. Pulps made by the sulphite process provide some of the best-known examples of the advantage of multi-stage bleaching, but of great interest also are bleached kraft pulps of high strength and good colour, as these have become available only relatively recently. The general principles of the preparation process are similar to those used for sulphite pulps and indicated above, but the results obtained almost justify the descriptions of a modern bleached kraft as a new raw material for paper. This is because, although the colour and cleanliness bring these pulps into favourable comparison with many grades of bleached sulphite pulp, the corresponding strength is very much greater, and the cost is not excessive. It is believed that the advent of this new type of pulp may create a demand for a paper which combines the strength of the familiar brown kraft wrapping with the æsthetic and advertizing value which result directly (and indirectly, through the printer's art) from a good colour; foodstuff wrappings suggest themselves immediately in this connexion; and substitution of certain grades of rag is another possibility.

The use of American southern pine as a source of paper-making wood-pulps other than kraft has already been referred to in NATURE[4], and the requirements of the rayon industry are now also being studied. In view of this work, there seems little doubt that it is only a matter of time before it is possible to deal with the vast supplies of southern pine by the groundwood process, and possibly even by a sulphite process. There are many who are sceptical about even the former of these possibilities; but it is less than seventy years ago that similar doubts were expressed as to the practicability of making paper from wood at all. When it is remembered that there are a hundred million acres of longleaf and loblolly pine available from the southern States of the Union alone, there is ample justification for the statement that this region may well be as important in the future as a source of newsprint as at present it is of kraft-pulp.

The exploitation of new sources of wood at once raises the general question of the conservation of timber supplies and, in particular, the matter of re-afforestation. One respect in which certain of the Scandinavian countries have set an example which might well be followed more closely elsewhere is the organization of the pulp-mill in close relationship to the saw-mill, with the object of eliminating waste. In this connexion, it was stated a few years back by the U. S. Forest Service that every year about six million cords of sound wood suitable in size for pulping processes were wasted in the course of logging operations. This statement refers to one of the richest timber regions in the world, namely, the strip of Pacific coastline between Oregon and Alaska. Here the western hemlock, which is very suitable for the production of sulphite wood-pulp, occurs in close association with an important timber tree, namely Douglas fir, and there are now possibilities that the latter might be amenable to treatment by the sulphate process.

In the case of southern pine, a relatively short time of growth—at the most eighteen years—is required in order to obtain a tree of suitable size for pulping, so that in this instance the problem of re-afforestation should be simplified, at any rate from the economic point of view.

A final word seems desirable on the subject of possible rivals to wood-pulp. These are not lacking, and many indeed (such as straw) precede it historically. Each year brings a host of suggestions which the paper-maker assiduously tests, and frequently finds to be satisfactory from a purely technical point of view. The objection is nearly always the cost of transport, because the fibres usually grow in remote parts of the earth where the cost of harvesting and bringing to the nearest port is prohibitive. The rapidly advancing price of wood-pulp is, however, focusing attention on the results of trials which have been 'filed' for many years. Esparto is of course an old-established rival to wood-pulp and one which enjoys the advantage of being a printing fibre *par excellence*, although it is too soft to be used alone where strength is at all important. At the same time, any decrease in the difference in price between wood and esparto must tend to increase the demand for the latter.

Another fibre which may assume more importance in the future is bamboo. It may be safely stated that the main technical difficulties associated with this fibre have now been overcome, and it is firmly established in India; Sabai grass, which produces a paper having similar characteristics, is also increasingly in evidence in papers from this source. Both types of paper are similar to those made from esparto, and give good printing results. To come nearer home, straw is a source of pulp which is encountered frequently in Continental papers, and particularly in those from agricultural countries such as Holland. Its use in recent years has been on the decline, but as this has been due mainly to the cheapness of wood-pulp, the removal of this competition should mark the revival of straw. Unlike esparto and bamboo, straw imparts a hardness and rattle to paper and has a good colour; it is therefore more suitable for writings than for printings. Although there is, and presumably always will be, plentiful supplies for pulping, the processing of it for use in fine papers will, however, be controlled to a great extent by the demands on the raw material made by the straw-board industry. Danubian reed (*Phragmites communis*) is also available in large quantities in the Danube valley, and a similar reed grows in the marshy districts of Norfolk. Many investigations into their paper-making properties have already been carried out both privately and in conjunction with the Ministry of Agriculture[5], and it was concluded that if it were not for the low yield the reeds might prove competitive with certain classes of wood-pulp; here again, therefore, rising prices may reverse the situation. Similar considerations apply to New Zealand flax[6] (*Phormium tenax*) and hemp stalks. The former is perhaps in a different strength category from wood-pulp, as its strength makes it more comparable with rags, but the latter is of considerable importance to countries such as Italy where some 400,000 tons of stalk are available per annum; this is sufficient to render this particular country self-supporting from the pulp point of view[7]. Here again, however, the rayon industry may claim a share of the new material.

Finally, the possibility of a paper pulp famine in the distant future is extremely remote, as even if wood-pulp supplies fail—an unlikely probability—human ingenuity will soon provide a substitute. On the other hand, the immediate future may be a period of difficulty which will last until the gap between past and future conditions is bridged, so that there is every prospect that the rapid advances in the technology of the subject will continue.

International Council of Scientific Unions

NINETY-EIGHT representatives of seven International Unions and twenty countries attended the third General Assembly of the International Council, held in the rooms of the Royal Society, London, under the presidency of Prof. N. E. Nörlund. At the opening meeting on April 27, the Council was first welcomed by Sir William Bragg, president of the Royal Society, and then Prof. Nörlund gave his presidential address on "The Figure of the Earth".

After the report of the Executive Committee had been read, Prof. B. Cabrera presented the report of a special committee which was appointed to consider the relations of the Council with the Committee of Intellectual Co-operation of the League of Nations. Among the recommendations of the committee, which were adopted in full, was one that the International Council should act as a consulting body on problems of a scientific nature which the Committee of Intellectual Co-operation might be called upon to solve. Questions of an international character concerning the organization of scientific work would be referred by the Council to the Committee. Prof. S. Chapman presented the report of the Committee on Solar and Terrestrial Phenomena, and the Committee was continued with an increased grant. The Committee on Instruments and Methods was discontinued.

The second session of the Council was largely devoted to the resolution from the Royal Academy of Sciences at Amsterdam asking for the appointment of a committee "which should attempt to arrive at a co-ordination of what has been proposed in respect of the social responsibilities of science and of scientific workers" (see NATURE, 139, 697, April 24, 1937). Prof. J. M. Burgers presented the motion, which led to a lively discussion in which eighteen speakers took part. It was clear that a number of the representatives of national academies adhering to the Council were not in a position to vote for the motion as it stood without reference back to their academies. A restricted field of activity was the most that could secure general support for a committee of the type indicated. The matter was referred to a small committee representative of the different views that had been expressed.

This committee reported that the appointment of a committee with the full powers proposed by the Amsterdam Academy lay outside the objects of the International Council as laid down in the statutes, and at a subsequent meeting of the Council Prof. H. R. Kruyt formally withdrew the motion from the Amsterdam Academy in favour of one to appoint a committtee with the following terms of reference:

"The Committee, at suitable intervals, should prepare a survey of the most important results obtained and of the directions of progress that are opening and of points of view brought forward in the physical, chemical and biological sciences, with reference to:—

"(1) their interconnections and the development of the scientific picture of the world in general;

"(2) the practical application of scientific results in the life of the community.

"The work of the Committee is limited strictly to scientific activity."

The membership of the committee was left to the Executive Council of the Union.

The reports of the recent work of the various International Unions were presented by Dr. H. Spencer Jones (Astronomy), Prof. M. de Martonne (Geography), Sir William Pope (Chemistry), Prof. H. Abraham (Physics), Prof. S. Chapman and Dr. J. de Graaf Hunter (Geodesy and Geophysics), Dr. E. H. Rayner (Radio Physics) and Dr. M. J. Sirks (Biology). Prof. E. V. Appleton completed the report from the Union of Radio Physics by a lecture at the Royal Institution on "International Co-operation in Radio Research."

The social side of the meeting included a reception by the Government at Lancaster House and one by the Royal Institution, at which Sir William Bragg lectured on "Classical Experiments made at the Royal Institution". The Royal Society invited delegates to attend one of its ordinary meetings and also one of its annual soirées. Visits were also arranged for those delegates who wished to see such institutions as the Royal Observatory, the Royal Geographical Society, Kew Gardens, Rothamsted, the Zoological Gardens, the National Physical Laboratory, the B.B.C., and various institutes, museums and laboratories in or near London.

At the closing meeting of the Council, the place and time of the next meeting were fixed as Copenhagen in 1940, on the invitation of the Royal Danish Academy of Sciences. After votes of thanks for hospitality and to Prof. Nörlund and Sir Henry Lyons for their past services, new officers were appointed as follows: *President*, Prof. Charles Fabry; *Vice-Presidents*, Il Marchese Marconi, Prof. H. R. Kruyt; *Members of the Executive Council* (in addition to representatives of the Union), Prof. D. B. Nemeč, Dr. J. A. Fleming; *General Secretary*, Prof. F. J. M. Stratton.

Obituary Notices

Dr. A. H. Church, F.R.S.

DR. ARTHUR HENRY CHURCH died on April 24 at the age of seventy-two years. At sixteen years of age he left his home at Plymouth, where his father was in business as a saddler, to be a pupil teacher at Ashburton Grammar School; four years later he entered University College, Aberystwyth, and at twenty-four was elected science scholar of Jesus College, Oxford. He was a research fellow of his College from 1908 until 1912 and University reader from 1910 until 1930. One married daughter survives him.

Church was not as other men: he went his own way, indifferent, so it seemed, to the opinions of his fellows; exceptionally able, he combined meticulous accuracy with originality and a flair for theoretical discussion. His contributions to botanical science bear the impress of a certain quality of distinction and genius. The greater part of his academic life was spent in the intensive instruction and paternal guidance of Oxford undergraduates, to whom he gave his best and earned their gratitude. To most botanists, he was known only by name and as the author of books and papers characterized by clear thinking, provocative, dogmatic statement and bold hypotheses often demanding concentrated thought on the part of readers. Well fitted by ability and breadth of knowledge to occupy the highest positions in his profession, his ambition was to advance science, not himself; life in the laboratory and in the seclusion of home sufficed; to the great regret of colleagues he avoided scientific meetings and social occasions.

A paper published in the *Annals of Botany* forty-two years ago on a calcareous alga, *Neomeris dumetosa*, illustrates Church's thoroughness in description, ingenuity in attacking theoretical problems, and his great skill as a draughtsman. At the beginning of the present century, Church devoted much time and thought to the mathematical laws governing the orderly disposition of leaves on stems of plants. Phyllotaxis, the arrangement of leaves on a shoot, is the expression of rhythmic production at the growing point: different plants have their own architectural plan. So much is known to students: most botanists are content to go no further. In his book, "On the Relation of Phyllotaxis to Mechanical Laws" (in three parts, 1901–4), and in a few shorter papers, Church made a comprehensive survey of the various types of phyllotaxis, and decided that a morphological theory of spiral growth must be based on a logarithmic spiral on a plane surface. This conclusion and the mathematical reasoning, it must be admitted, did not awake an enthusiastic response on the part of the average botanist.

In 1908 the Oxford University Press published a sumptuous folio volume "Types of Floral Mechanism" in which are described twelve early spring flowers with drawings, many in colour, which have never been surpassed in accuracy. A few years later, Church gave much pleasure to me by acting upon a suggestion that he should apply methods, previously used by him in the description and delineation of Angiosperm flowers, to the elucidation of the floral morphology of the remarkable African Gymnosperm *Welwitschia mirabilis*. The results were communicated to the Royal Society in 1914. A series of "Elementary Notes" on Angiosperms, Gymnosperms and Fungi (1919–21), printed as pamphlets, that are models of concise and logical presentation of facts and theories, bear testimony to his determination to raise the standard of teaching to the highest level. Three admirable botanical memoirs on "Plant Life of the Oxford District" have much more than a local value and should be more widely known.

The best known of Church's Oxford Memoirs is "Thalassiophyta and the Subaerial Transmigration" (1919). The opening words, "The beginnings of Botany are in the sea", served as a text for a learned and exceedingly interesting thesis on the origin of terrestrial vegetation. His view was that life began in a primeval ocean covering the surface of the earth; free-swimming flagellates were succeeded by encysted organisms attached to the sea-floor, some of which in the course of ages developed into highly differentiated green algæ comparable in size and complexity to the large brown seaweeds of our rocky coasts. At a later stage, portions of the earth's crust were uplifted above the surface of the world-ocean, and some of the aquatic algæ that had reached an advanced state of differentiation were, he believed, able to grapple successfully with the serious problems presented by a changed environment and became the advanced guard of a land flora: "the origin of all the main successful adaptations of the land are to be traced down to the benthic phase of the sea". The Thalassiophyta memoir was preceded by one on "The Building of an Autotrophic Flagellate" (1919). He afterwards published several papers in the *Journal of Botany* (1924–25) and elsewhere in elaborating the main thesis.

Church's fascinating hypothesis, not perhaps wholly new, was presented by him in an original form and with a wealth of argument and fact: it has been vigorously criticized by botanists who envisage a different origin of land vegetation; but to many it makes a strong appeal as a contribution to speculative science which will endure.

Forgetting his idiosyncrasies and regrettable aloofness, we think of Church as a self-sacrificing, devoted, kind-hearted teacher, and as one of the ablest and most original botanists of our time.

A. C. SEWARD.

Diwan Bahadur L. K. Ananthakrishna Iyer

WE much regret to announce that Dr. Ananthakrishna Iyer, whose name is well known to all students of Indian sociology, died on February 25 at Palghat in the Malabar district of the Madras Presidency.

Born of a southern Indian Brahman family at Palghat in 1861, and educated at the local Government high-school, this well-known scholar graduated at the University of Madras and entered Government service, which he soon relinquished to join the staff of the Victoria College at Palghat. He then became an inspector of schools in the Cochin State, in which position his services were utilized to develop a State museum, zoological gardens and an industrial bureau. Thus he possessed suitable qualifications for taking part in the systematic ethnographical survey of India which was set on foot by the late Sir Herbert Risley as a sequel to the Census of 1901. Two volumes dealing with the tribes and castes of the Cochin State were issued by him in 1907 and 1912 respectively. The University of Calcutta then invited him to organize a Department of Anthropology, of which he became chairman in 1920.

When in 1924 the superintendent of the Mysore Ethnographic Survey, Mr. H. B. Nanjundayya, unfortunately died, leaving the Survey only partly accomplished, the Mysore State selected Ananthakrishna Iyer to succeed him. Thus commenced the most important of the latter's numerous tasks, and one which will serve as a lasting memorial to his energy and powers of research. Between 1924 and 1935, four volumes were published, giving an account of the population of Mysore on the lines laid down for the Ethnographical Survey, and containing a mass of interesting materials skilfully marshalled by the editor. The first volume, published last, contains a summary of the contents of the other three, and is enriched by contributions from such scholars as Dr. R. R. Marrett, M. Sylvain Lévi, Baron Eickstedt and Mr. C. S. Richards. The public were promised a further volume containing some additional materials, but it is feared that this may not now be available. The loss would be regrettable as it was expected to remedy an obvious defect in the first four, namely, an omission of any list of tribal and caste synonyms, an indispensable guide for scholars who are not familiar with the many names under which Indian social divisions are frequently hidden.

While preparing his final effort, in relation to Mysore, Ananthakrishna Iyer attempted a survey of the small State of Coorg on parallel lines. It is understood that this work was well advanced at the time of his death. It is therefore earnestly hoped that the completion and publication will be entrusted to some competent scholar by the Coorg State.

As a foundation member of the Indian Science Congress, Ananthakrishna Iyer endeavoured to popularize the study of anthropology. In 1934, he was invited by a number of universities in Europe to deliver lectures, and for this purpose visited Oxford, Paris, Rome, Florence, Vienna, Berlin, Königsberg, Halle, Bonn and Cologne. In July of that year, he was present at the International Anthropological Congress in London when he read a paper on the agricultural basis of religion in southern India, and directed attention to the somewhat inadequate provision made on this occasion for the consideration of the results of Indian ethnographical research. In January last, he presided for the last time over the Anthropological Section of the Indian Science Congress Association, held at Secunderabad, when he dealt in his presidential address with his recent work in the Coorg State.

Ananthakrishna Iyer's publications are too numerous to mention here. During a period of forty years he was connected with most of the learned societies dealing with anthropology in Europe and America. He was a foundation fellow of the Indian Academy of Science, Bangalore, and of the National Institute of Science, Calcutta. In 1935 he was made officier de l'Académie Française and honorary doctor of medicine and surgery of Breslau. In the same year he was promoted from Rao Bahadur (1921) to Diwan Bahadur, by the Government of India. By his death, India loses an indefatigable and learned worker in the field of ethnographic study who cannot readily be replaced. His many friends both in that country and in England will regret the passing of an attractive and vigorous personality.

R. E. ENTHOVEN.

Dr. T. G. Macaulay Hine, O.B.E.

DR. T. G. M. HINE, who died on April 25 at the age of sixty-six years, was the son of the late Mr. George Hine, an architect in large practice. From close association with his father, Hine acquired an excellent knowledge of business, and in his youth spent a year in Germany at the practical study of engineering. Educated at Charterhouse, King's College, Cambridge, and St. Bartholomew's Hospital, Hine, after qualifying and acting as house physician, settled down to the study of bacteriology and investigated the fermentative character of organisms of the diphtheria group.

Hine's chief chance, however, came when during the first winter of the Great War cerebrospinal fever broke out among the mass of troops then in training and, as recruits are specially susceptible to the disease, a very serious outbreak was threatened. The disease was known to be due to the meningococcus and to be conveyed by droplet infection through a chain of healthy carriers who harbour the organism temporarily in their nasopharynx. The D.G. of the Army Medical Service, the late Sir Alfred Keogh, was advised as to the measures taken by Sir William Horrocks assisted by the late Dr. Richard Reece and Dr. Mervyn Gordon, whose services were supplied by the Medical Research Committee. A central laboratory was set up at Millbank (headquarters of the R.A.M.C.) with a travelling laboratory attached and Dr. Hine was put in charge. In order to check the disease, contacts were swabbed, carriers segregated, and intensive research undertaken in which Martin Flack, W. J. Tulloch, J. A. Glover, and A. G. Bell all made valuable contributions.

As each salient point came to notice it was applied by Dr. Hine. Thus (1) the first requirement was a suitable medium that could be supplied in bulk for identifying carriers of the meningococcus. When this was arrived at, Dr. Hine manufactured it on a large scale and kept more than fifty laboratories dealing with troops supplied. (2) It was soon found that the only safe way to identify the meningococcus was by serological means, and that four different types of it were operating, of which two were responsible for 80 per cent of the cases. The large-scale production of menotypical agglutinating serums for identifying these strains of the meningococcus, and homologous suspensions for checking the sera, was undertaken by Dr. Hine, who later on was succeeded in this work by Commander A. G. Bell. (3) When trial was made of monotypical therapeutic serum standardized by its antiendotoxic capacity, Dr. Hine undertook its distribution and the assessment of results. This serum was particularly successful in patients infected by Type I, the main epidemic strain of the meningococcus, in which the mortality had previously been highest, but less successful in cases infected by the other types. (4) When it was found by experiments on carriers at the central laboratory that the meningococcus can be destroyed in their nasopharynx by causing them to inhale through the nose the air of a room densely charged with a spray of droplets of 1 : 50 zinc sulphate, Hine's previous engineering experience enabled him to design a jet that was more efficient than the one previously in use.

Although the disinfection of carriers by this means was only temporary, it proved valuable for dealing with instances of mass infection, and when applied the last thing at night before going to bed, appeared to stop the incidence of the disease in some outbreaks: the disease ceasing while the spray treatment was in use and beginning again when it was stopped. The Navy adopted Hine's jet for installation in the Fleet, where it was operated by compressed air instead of by steam as in the Army.

For his services during the War, Dr. Hine received the O.B.E. and was made an honorary major in the Army. After the War, he gave assistance for a time to the administrative staff of the Medical Research Council and then retired to his house near Slapton in South Devon. Dr. Hine was a popular figure in lay as well as medical circles, and was a past Master of the Fruiterers' Company.

WE regret to announce the following deaths:

Prof. R. H. Fernald, director of the Department of Mechanical Engineering and dean of the Towne Scientific School of the University of Pennsylvania, known for his work on fuel technology, on April 24, aged sixty-six years.

Prof. A. R. Ling, emeritus professor of malting and brewing and of the biochemistry of fermentation in the University of Birmingham, on May 14, aged seventy-six years.

Prof. L W. McCay, emeritus professor of chemistry in Princeton University, known for his work on the chemistry of arsenic, on April 13, aged seventy-nine years.

News and Views

Dr. G. F. Herbert Smith

DR. G. F. HERBERT SMITH retires from the keepership of minerals in the British Museum (Natural History) on May 26. He joined the staff of the Mineral Department under Sir Lazarus Fletcher in 1897 and devoted himself particularly to mathematical crystallography and to the development of scientific methods for the identification of gem-stones. An account of his earlier career and of his scientific work appeared in these pages in 1935 (135, p. 948). In 1921 he was appointed assistant secretary and later secretary, of the British Museum (Natural History). This was a loss to the Mineral Department, but an undoubted gain to the Museum as a whole. During his fourteen years in this office he worked for the improvement of the equipment and buildings of the Museum, and the increase of numbers and betterment of conditions of employment of its staff, and for the prestige at home and abroad of a great scientific institution. During his short period of office as keeper of minerals since 1935, he has continued the improvement in display methods initiated by his predecessor. The finely illuminated wall-cases at the entrance to the mineral gallery and the nitrogen-filled case housing the great Cranbourne meteoric iron have all been completed under his supervision. With the office of secretary to the Museum he took over the secretaryship of the Society for the Promotion of Nature Reserves and he has been chairman of the Wild Plant Conservation Board since 1931. These activities will not cease with his retirement from the Museum, and it may be hoped that time may also be found for a resumption of scientific work interrupted by many years of administrative duties. Quite apart from his scientific work, Dr. Herbert Smith has taken a very active part in Civil Service affairs. He was one of the honorary secretaries of the Society of Civil Servants in 1918–1925, vice-president in 1925–1928, and president in 1928–1932. He has been honorary secretary and treasurer of the Civil Service Arts Council since 1924.

Lieut.-Colonel W. Campbell Smith

LIEUT.-COLONEL WALTER CAMPBELL SMITH has been appointed to succeed Dr. Herbert Smith. Lieut.-Colonel Campbell Smith was born in 1887 and educated at Solihull and Corpus Christi College, Cambridge. He took a first class in both parts of the Natural Sciences Tripos (Mineralogy), and was appointed to the Museum in 1910, where his work has been confined mainly to the collection of rocks, which has been entirely rearranged in his time. He was promoted to deputy keeper in 1931. At the outbreak of the Great War he was a lance-corporal in the Artists' Rifles, was later seconded to the Special Brigade, R.E., and rose to the rank of lieutenant-colonel in 1918. He resumed his connexion with the Artists' Rifles after the War and retired in 1935 with the rank of brevet lieutenant-colonel. He was secretary of the Geological Society of London in 1921–1932, and has been secretary of the Mineralogical Society since 1927. He was a fellow of Corpus Christi College, Cambridge, in 1921–24, and is a governor of the Royal Holloway College.

Pulitzer Prize for Science Reporters

THE Pulitzer prizes in letters and journalism for the current year were announced on May 3 by Dr. Nicholas Murray Butler, president of Columbia University. Among the awards was a prize of one thousand dollars to five members of the National Association of Science Writers, all of whom have reported the meetings of the American Association for the Advancement of Science for many years. The award, "for the most distinguished example of a reporter's work", was given in recognition of their accomplishments in connexion with the tercentenary celebration of Harvard University. The criteria on which the award is made are "strict accuracy, terseness, the preference being given to stories prepared under the pressure of edition time that redound to the credit of journalism". Those sharing the reward are: Howard W. Blakeslee, Associated Press, president; William L. Laurence, *New York Times*, vice-president; David Dietz, Scripps-Howard Newspapers, past president; Gobond Behari Lal, Universal Service; and John J. O'Neill, *New York Herald-Tribune*. The work of reporting the celebration was carefully organized in advance by the Harvard authorities in co-operation with the National Association of Science Writers, the president of the University, Dr. Conant, giving personal attention to the matter. The result was eminently satisfactory, and the award of the Pulitzer prize to the five writers mentioned is an encouraging mark of appreciation of the way in which a great university function was described in the periodical press.

The Coronation Broadcast

THE modern development of radio broadcasting is among the most wonderful and at the same time the most satisfactory, of the practical applications of scientific and technical research. This was admirably demonstrated on Coronation Day, May 12, when the elaborate arrangements outlined in NATURE of May 1 were submitted to the test of practical achievement. For more than six hours, almost the entire resources of the British Broadcasting Corporation were devoted to the handling of a sound picture of the procession and coronation ceremony from start to finish. In addition, at a selected point on the route, a combined sound and vision programme was successfully broadcast from the London television station, while, later in the day, a 'round the Empire' programme concluding with an address from H.M. the King was also provided. All those concerned must feel a deep sense of satisfaction in the successful accomplishment of this day's difficult programmes. For the first time in history, the general public in all parts of the world were enabled to participate in very intimate detail in the elaborate ceremony of the coronation of a British king. Hitherto this experience has been confined to the few who, by virtue of rank or service, have been favoured with a position inside Westminster Abbey.

CORONATION DAY, 1937, will be remembered by many millions of people who heard, either in their own homes or while they were actually in position along the processional route, a continuous broadcast commentary accompanied by a sound picture background of the pomp and majesty of the procession and ceremony. A striking illustration of the advantages which broadcasting gives over the possible scope of the ordinary sightseer, was provided by the manner in which the commentary was successively switched forward along the route, so that the listener was enabled to keep up with the progress of the procession. When, as seems undoubtedly probable in the near future, this advantage becomes available to the viewer as well as to the listener, it will be still more generally appreciated. When the picture is further provided in natural colours, the entire scope of the participation of the general public in large-scale ceremonies will have been subject to a revolutionary change.

THE evening programme comprised messages of homage to the new King, presented by speakers in various parts of the Empire in addition to the official greetings from the Prime Ministers or other representatives of the Dominions actually present in London. This expression of homage from the Empire concluded with a speech by H.M. King George VI, who himself recorded the fact that this was the first time that the King had been able to address the nation as a whole on the day of his coronation. Messages congratulating the B.B.C. on these impressive broadcasts have been received from all parts of the Empire and from many foreign lands. These marked the successful use of the two new 50 kW. transmitters at the Daventry short-wave station supplementing the older 10 kW. sets. In many cases, the resulting reception was so satisfactory as to permit the rebroadcasting of the programme through all local transmitters. For example, in Melbourne the broadcast was retransmitted from ninety-seven stations throughout Australia. The Corporation's aim to supply the whole world with an effective broadcasting service was thus realized on this occasion. Truly may it be said that radio broadcasting is a very potent factor in bringing together the peoples of the world to a closer union which should result in greater friendliness and understanding.

Natural Limits of Human Flight

IN his presidential address delivered before the Royal Aeronautical Society on April 26, Mr. H. E. Wimperis discussed the "Natural Limits of Human Flight". He showed how relatively thin is the atmospheric shell in which we live. Birds, he considers, have reached the limits of perfection in natural flight, comparatively little progress having been made in the last thirty million years, whilst the "present attainments in human flight have all grown from the endeavours of a single generation". With regard to high speed, increase in altitude of flight does not necessarily mean an increase in speed, but depends largely upon the supercharging of the engine. Increase of altitude has also other detrimental effects, for example, increase of drag coefficient due to decrease of Reynolds' number, and increase in induced drag due to the increase in incidence when flying near the 'ceiling'. Actual increase in the size of aircraft would raise the speed; but not beyond a certain point, unless more engine power can be got from a given space, or some means found of reducing the drag by changing the turbulent flow to a laminar one. Progress along these lines will soon bring us to the most formidable obstacle of all, namely, the compressibility of the air as the speed of sound is approached; and this Mr. Wimperis regards as being well above the limit obtainable with engines of the type in use to-day, which he placed as between 500 and 600 m.p.h.

POWER of manœuvre was the next point considered by Mr. Wimperis. Speed of dive, which also involves large changes in altitude, has apparently no harmful effects on the personnel of an aircraft. On the other hand, rapid changes in direction or speed bring into play accelerations which impose severe physiological effects on the personnel, and limit the maximum acceleration to the order of ten times gravity. Consequently, with steadily increasing speeds the rate of manœuvre must thus be correspondingly decreased. With regard to the limit of altitude, provided oxygen apparatus is used, flights at 80,000 feet are possible, but increase in altitude above the present limit of 50,000 feet will be restricted to 60,000 feet largely by supercharging difficulties alone. Speaking of the range of flight, Mr. Wimperis said that it is difficult to set a limit to it. In still air, range is independent of altitude and depends chiefly on engine fuel consumption economy, low drag, low structure weight, coupled with large fuel capacity. He also expressed the opinion that aircraft as weapons of attack in warfare will, in the future, not occupy such a favourable position as in the past.

Long Ashton Research Station

THE annual open day of the University of Bristol Research Station at Long Ashton was held on May 6, when horticulturists, cider makers and fruit growers assembled to sample the ciders and other fruit products of the current season. Prizes awarded for the production of cider fruit were presented by Lord Faversham, Parliamentary Secretary to the Minister for Agriculture, after a speech which was broadcast from the West Regional Station. The results of recent investigations in cider making were on view. These included the use of German wine yeasts such as Waldenberg, Steinberg and Zeltingen instead of natural cider yeasts, to obtain finer flavour. Artificially and naturally sweetened ciders have been compared, and apple juice has been successfully concentrated for storage purposes. The production of non-alcoholic apple juices has received considerable attention in the past year. Various combinations of dessert, culinary and cider varieties have been used for this purpose, and the effects of aeration and pasteurization studied. Seitz-filtered still juices are considered the most attractive, pasteurization having an adverse effect on flavour. As a result of the work at Long Ashton, commercial production of syrups from pure soft-fruit juices is now in operation on a large scale, and the numerous domestic uses of these products were illustrated by an exhibit of milk shakes, jellies, cake fillings, etc.

EXPERIMENTS in progress on the extensive fruit plantations of the Station were open for inspection. These include investigations on the manuring of apples and soft fruits, pruning and shaping of fruit trees, rootstock trials with apples, pears and plums, and the influence of cultural treatment on the storage qualities of apples. Of particular interest on this occasion was the attempt to grow cider varieties of vintage quality as bush trees. If this can be accomplished, crops may be borne in a much shorter time than by the usual method of standard tree production. The propagation of basket and cricket bat willows also aroused considerable interest. Progress in methods of pest and disease control was illustrated by exhibits in the laboratories, a recent development being the use of cuprous oxide as a seed treatment for early peas and zinc oxide for ornamentals. The control of plum sawfly and red spider was demonstrated by the use of combined washes containing white oil emulsion and rotenone-containing substances. In addition to horticultural research, the extensive agricultural advisory service of the Station was evident from the exhibits on dairy bacteriology, methods of pig husbandry and the economic feeding of dairy herds.

The Patent Office Library

ON May 3 Dr. Leslie Burgin, M.P. (Parliamentary Secretary of the Board of Trade), accompanied by the Comptroller-General of Patents and other officials, received a deputation from the Parliamentary Science Committee which placed before him its report on various desired improvements in accommodation and other amenities at the Patent Office. The deputation was introduced by Lieut.-Colonel Sir Arnold Wilson, M.P. Dr. Burgin expressed himself most sympathetically towards the points raised, several of which, he stated, were already being dealt with, or were in contemplation. He was precluded at present from discussing the provision of a set of duplicate search files by the adverse findings on that subject of the Sargant Committee of 1931. If, however, the Parliamentary Science Committee presented a detailed case strong enough to justify him in re-opening that subject, he would not bar and bolt the door; but the onus of justification must rest with the Committee. Dr. Burgin stated that an extension of the Patent Office buildings was contemplated during the next few years which would allow for increased library space. On the subject of binding, he said that allocations amounting to £3,100 had been made since the Great War for the purpose of overtaking arrears, apart from substantial increases in the grant for books and binding, which had permitted of enlarged purchases of foreign publications. If the Committee would provide him with specific particulars of the foreign publications and periodicals which, in its opinion, should be added to the Library, every endeavour would be made to meet such suggestions. The deputation was satisfied that improvements in the services afforded by the Patent Office Library are in hand, and that the importance of the matters laid by them before the Board of Trade was fully appreciated by Dr. Burgin and by the officials concerned.

Preservation of Monuments of Antiquity

IN a period of economic transition such as the present, the future of many monuments of antiquity, now in private ownership, even when under the protection of the Office of Works, must continue to be precarious, owing to the breaking up of large estates. Private benefaction and public response to appeal in cases of urgent necessity have been generous in recent years; but they cannot be expected to shoulder the burden indefinitely. The strongest safeguard for the less widely known, but often none the less important antiquities, which necessarily must run the greater risk, is a vigilant educated public opinion, backed by an enlightened authority. An example of the effective application of existing legislation in such conditions is afforded by the recent public inquiry at Worthing on a proposal to develop Highdown Hill between Worthing and Littledown as a building estate (*The Times*, May 13). On account of the natural, archæological and historical interest of the site, this inquiry, held by order of the Ministry of Health, is to be regarded as of considerable importance. The Hill, a southern outlier of the South Downs, rises to a height of two hundred and sixty-nine feet, and is an important feature in the maritime level tract, which is visible from far along the coast. On the summit is an earthwork, of at present uncertain age, in which was discovered in 1892 an important sixth century Anglo-Saxon cemetery. In it were eighty-six burials lying east and west in rows. The contents of the graves, of which the ornamentation suggested Frankish affinities, made this one of the most important finds of its kind in Britain. Yet the site was not scheduled under the Ancient Monuments Acts until 1930, and then only as the result of public protest, when the estate was offered for sale. The present inquiry was held on an appeal from the owner against a refusal of the Worthing Rural District Council to grant an interim development order. It was opposed by the Worthing Rural and Town Councils, the West Sussex County Council and four adjacent owners. A public-spirited offer has been made by the local authorities to accept any financial responsibility involved in the preservation of the site.

The Cerne Giant

THE 'Cerne Giant', it is announced, will come under the auctioneer's hammer on June 16 next when the Abbey estate, Cerne Abbas, near Dorchester, Dorset, is to be sold in lots. The 'Cerne Giant' is one of a small group of remarkable and curious antiquities of Britain which were described by Sir Flinders Petrie some years ago in a special publication of the Royal Anthropological Institute. They are figures of considerable size cut in the turf on the chalk in outline. They are of unknown purpose and unknown age, though almost certainly some, if not all, are prehistoric. The best known, owing in part to its appearance in popular fiction, is the Berkshire 'White horse', but the 'Wilmington giant' in Sussex and the 'Cerne Abbas giant' are almost equally famous. The 'Wilmington giant' is on a slope so steep as almost to appear to be standing upright. The 'Cerne giant' is on Trendle or Giant's Hill, and is a huge ithyphallic figure, one hundred and eighty feet high, brandishing a club, which is one hundred and twenty feet long and in breadth runs from seven to twenty-four feet. The head appears disproportionately small. The outline is cut in trenches two feet broad by one foot deep. The 'Wilmington giant' is rather larger, being approximately two hundred and forty feet high, with a head of twenty-one feet breadth. Various explanations of the giants' figures have been put forward. It has been suggested that the 'Cerne giant' is the figure of the Saxon god Heil, but in all probability it is much older, possibly Iron Age. The circle above the figure of the giant in which the Cerne maypole used to stand, together with the ithyphallic character of the figure, support the obvious attribution to a very ancient fertility cult. The remarkable character of the figure and its great interest for the light it throws on ancient British culture make it regrettable that the ground on which this figure is cut should be in private ownership and subject to such vicissitudes as that now impending.

Archæological Investigations in Cilicia

A DISCOVERY of much interest in relation to the sources of supply of material for implements in the prehistoric period of the eastern Mediterranean and western Asia was the subject of reference by Prof. John Garstang in an account of recent excavation on Hittite sites in Cilicia delivered before the Society of Antiquaries of London on May 6. Archæologists have sought for some time sources of the supply of obsidian, the rare volcanic glass from which the finer types of stone implements were fashioned in Egypt, the Aegean, Greece and western Asia, and of which for long the only source known to have been available for these areas was the island of Melos. An outcrop of this material several miles across, Prof. Garstang states, has now been discovered at the foot of Mount Argaeus in Anatolia. It shows many traces of having been worked in antiquity, and implements of this material, with others of chert, have been found in the lower levels of one of two interesting sites near Mersin. The site in question, on a small river Souk Su (Cold Water), showed signs of a pre-Hittite occupation of possibly so much as two thousand years. In describing the results obtained by the Neilson expedition to Cilicia, Prof. Garstang said that twenty-three sites on the plain of Adana had been examined, some of which yielded superficial evidence of Hittite occupation. Four sites had been opened in co-operation with the Government Museum at Adana. These included the mound at Serkeli on the east bank of the ancient Pyramus, where the important imperial Hittite monument was studied. On the mound of Kazanli, between Tarsus and Mersin, evidence was found of Hittite occupation extending from between 2400 B.C. and 2200 B.C. down to the Assyrian invasions. Prof. Garstang believes that the fall of the Hittite capital on the plateau did not involve the destruction of the Hittite centres of Cilicia.

Electricity in the Hospital

THE Faraday Lecture of the Institution of Electrical Engineers was given on May 6 by Mr. R. S. Whipple, on the subject of "Electricity in the Hospital". Dealing separately with lighting, power, heating, medical treatment and intercommunication, Mr. Whipple could easily convince his audience of the enormous call made on the electrical engineering services of a big hospital. He gave an estimate of the X-ray photographs taken annually by the largest ten hospitals in London as a million. Electro-medicine has indeed gone a long way from the methods of the seventeenth century, when a cure for paralysis was sought by giving the patients shocks from Leyden jars. Mr. Whipple passed in review the instruments devised especially for medical use, with special reference to the electro-cardiograph and the various diathermy machines; these were also shown in action.

New Zealand Handbook

ON the occasion of the meeting of the Australasian and New Zealand Association for the Advancement of Science at Auckland on January 12–19 this year, a useful handbook to New Zealand was issued to members. The book contains some thirty short articles on various aspects of the country, but the greater part is concerned with the geology, natural history and native population. Among the most valuable chapters are those on the climate by Mr. E. Kidson, the geomorphology of Wellington by Prof. C. A. Cotton, the economic geology of New Zealand by Mr. J. Henderson, the ecology by Mr. H. H. Allan and the forests by Mr. E. P. Turner. The volume gives in a collected form a great deal of precise information which is not otherwise easily accessible. The chapter on New Zealand's economic history discusses the future development of the resources of the Dominion.

Christ's Hospital and Prof. Armstrong

THE annual report of the Headmaster of Christ's Hospital contains the following reference to Prof. H. E. Armstrong, who, as many of our readers know, has been confined to his room for several months, though he maintains his interest in scientific and educational activities: "Illness has deprived the Committee of Education of the attendance of Prof. Armstrong, who, as a member of the committee for nearly forty years and latterly as chairman, may claim a large share in the formation and guidance of the Hospital's educational policy and ideals. It is a consolation to know that in his position as educational adviser to the council we shall still have the benefit of his wide knowledge and wise direction. We consider ourselves very fortunate to have as the new chairman of the Committee, the Rev. Prebendary A. Chilton, who brings to this work the special knowledge both of an old Blue and of a distinguished headmaster."

Announcements

AT a recent meeting of the Lawes Agricultural Trust Committee, Lord Clinton tendered his resignation as chairman owing to ill-health, and Prof. H. E. Armstrong was appointed in his place. Sir Merrik Burrell, lately president of the Royal Agricultural Society of England and chairman of its Research Committee, was appointed vice-chairman.

WE regret that the name of Sir Cuthbert Wallace, president of the Royal College of Surgeons, who has been made a baronet, was omitted from the list of Coronation honours published in NATURE of May 15.

THE eighth annual Haldane Memorial Lecture at Birkbeck College, London, will be delivered by Sir Arthur Eddington, director of the Observatory and Plumian professor of astronomy in the University of Cambridge, on May 26 at 6 p.m. The subject of the lecture will be "The Reign of Relativity 1915–1937". Admission is free, without ticket.

THE silver jubilee of the Chadwick Lectures occurs this year and the Chadwick Trustees are holding a reception for their former and recent lecturers, scholarship holders and recipients of Chadwick Medals and Prizes, to precede the lecture on May 26 by Prof. J. G. Fitzgerald, to be given at Manson House, 26 Portland Place, at 5.30 p.m. Dr. Fitzgerald is director of the School of Hygiene and the Connaught Laboratories, and professor of hygiene and preventive medicine in the University of Toronto. He is now on a year's leave of absence for the study of the teaching of preventive medicine in medical schools in the United States, Canada, the British Isles and other countries of Europe, for the Rockefeller Foundation. The title for Dr. Fitzgerald's lecture is "Preventive Medicine—an Avenue of Good Will". This will be the initial lecture of a series on public health questions by representatives of Overseas Dominions.

THE following appointments and promotions have recently been made in the Colonial Service: J. Glover, second plant physiologist, East African Research Station, Amani, Tanganyika; K. Wilkinson, European assistant, Meteorological Service, East Africa; N. S. Haig (agricultural officer), senior agricultural officer, Uganda; M. C. Abraham (assistant irrigation engineer), irrigation engineer, Ceylon; F. H. Clarke (assistant game warden), senior assistant game warden, Kenya; W. G. G. Cooper (geologist), assistant director of Geological Survey, Gold Coast; S. G. Taylor (irrigation engineer), divisional irrigation engineer, Ceylon; A. P. Weir (irrigation engineer), divisional irrigation engineer, Ceylon.

AT the forthcoming meeting of the National Peace Congress, which will be held at Friends' House, Euston Road, London, on May 28–31, a meeting of the Science Commission is to take place with Prof. S. Chapman in the chair. Prof. P. M. S. Blackett will open the discussion on "The Responsibility of the Scientist in Relation to Peace Problems". Further information concerning the National Peace Congress may be obtained from the Secretary, 39 Victoria Street, London, S.W.1.

AN informal conference on "The Conduction of Electricity in Solids" will be held at the H. H. Wills Physical Laboratory, University of Bristol, under the joint auspices of the Physical Society and the University of Bristol, on July 13–16. Several morning and afternoon discussions have been arranged. Among those who will take part in the discussions are: Prof. R. W. Pohl (Gottingen), Dr. J. H. de Boer (Eindhoven), Prof. Borelius (Stockholm), Prof. W. L. Bragg, Dr. C. H. Desch, Prof. G. I. Finch, Dr. E. T. S. Appleyard and Prof. J. E. Lennard-Jones. The conference will be open to members of the staffs of universities and research institutions. Further information can be obtained from Prof. A. M. Tyndall or Prof. N. F. Mott, H. H. Wills Physical Laboratory, The University, Royal Fort, Bristol, 8.

A CATALOGUE of rare and valuable books (No. 609) from Francis Edwards, 83 Marylebone High Street, W.1, contains some unusually interesting volumes of voyages, including Champlain's "Les Voyages de la Nouvelle France Occidentale" (1632), Hearne's "Journey from Hudson's Bay to the Northern Ocean" (1795), Linschoten's "Discours of Voyages into ye Easte and Weste Indies" (1598), Martyr's "History of Travayle" (1577) and a unique item in the form of a twelve-page print of a letter from Sir Joseph Banks describing his voyage with Captain Cook in 1768–71.

THE Oxford University Press announces that "The Science of Petroleum", edited by Dr. A. E. Dunstan, Prof. A. W. Nash, Sir Henry Tizard and Dr. A. B. T. Brooks, is approaching completion. The publishers expect to issue it in three volumes, each containing about one million words, during this summer. It contains about four hundred articles, written by three hundred contributors drawn from all parts of of the world.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 887.

Correspondents are invited to attach similar summaries to their communications.

Resistance Thermometry below 1·0° K.

During an investigation of the thermal coupling between the ionic magnets and the lattice vibrations of paramagnetic salts in the neighbourhood of the absolute zero, we have made some resistance measurements in the temperature range below 1° K. The resistance measured consisted of a specimen of fine phosphor-bronze wire very kindly supplied to us by Prof. Keesom of Leyden.

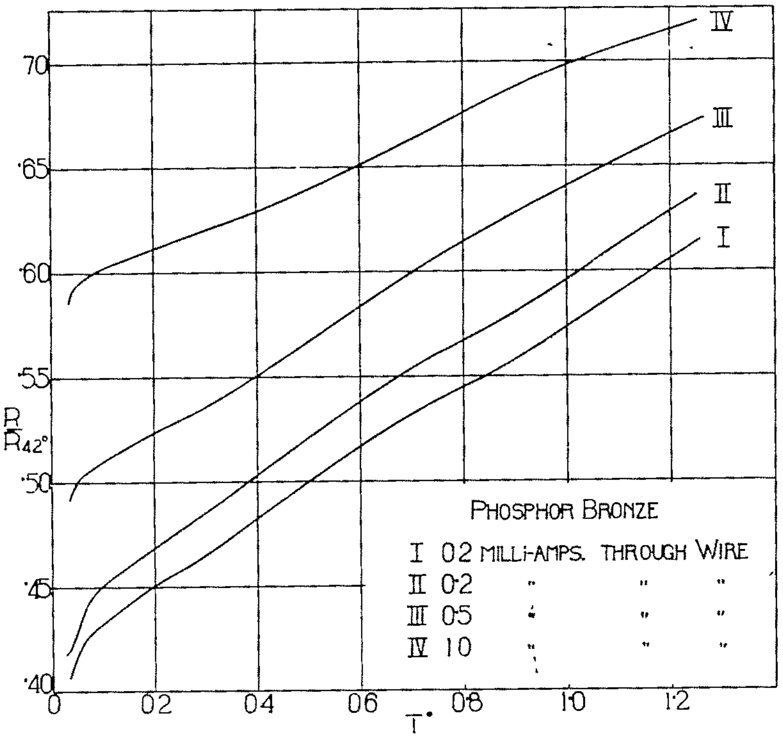

Fig. 1.

The measurements are shown graphically in the accompanying diagrams. The low-temperature unit used to obtain Curves I, III and IV was composed of a cylindrical bomb of German-silver with internal dimensions 70 mm. by 8 mm. The bomb contained grains of iron ammonium alum varying in size from 0·25 mm. to 0·5 mm., and helium at a room-temperature pressure of 120 atmospheres. At the lowest temperatures, the helium was in the liquid II phase, which has been found by Keesom[1] to have a very high thermal conductivity and therefore provided good thermal contact between the salt and the bomb casing. The phosphor-bronze thermometer was wound on the bomb and insulated from it by means of a layer of adhesive cellulose tape. For Curve II the unit was simply a cylindrical tube of German-silver into which iron ammonium alum was hydraulically compressed. From results to be published shortly, it was found for both units that thermal equilibrium between the paramagnetic temperature and the resistance thermometer was maintained down to the lowest temperature reached. By using high-resistance manganin leads, and by having thermal contact between the leads and the liquid helium bath at about 10 cm. above the bomb, warming-times were obtained between extreme low temperatures and the bath temperature which varied from more than an hour for Curves I and II to twelve minutes for Curve IV. The helium bath temperature was 1·25° K., and the demagnetizing field 20 kilogauss. The resistance measurements were made on a Tinsley thermo-electric potentiometer, and the specimen had a resistance of 2·5 ohms at 4·2° K.

In the diagrams the resistance ratios are plotted against T^*, the temperature deduced from susceptibility measurements on the assumption that Curie's law holds for iron ammonium alum throughout the range of temperature involved. Simon[2] has shown, however, that Curie's law does not hold for the salt below 0·1° K., there being a maximum departure at 0·06° K. as well as a sudden bend in the susceptibility curve at 0·034° K., which is interpreted as the Curie point of the salt. Simon's T^*-T relation was determined for an ellipsoid of salt of 6 : 1 length to diameter ratio. Simon claims accuracy to within only 10 per cent in his T^*-T relation, although the shape of the curve is held to be correct. Our specimens were roughly cylindrical of 8 : 1 ratio, and in the case of the bomb containing small salt particles had quite a different density factor from that of Simon's solid ellipsoid. In view of the above, and since our potentiometer measurements are correct only to the third significant figure in the ratio $R/R_{4\cdot2°}$, we decided not to attempt any reduction of our T^* values to absolute values of the temperature. The most that can be said is that our T^* is almost certainly not more than 0·02° lower than T in the neighbourhood of 0·06° K., and differs by less than that both below and above that temperature. The size of the discrepancy near 0·034° K. can be deduced from Fig. 2. At the Curie point (0·034° K.), according to Simon, the $T^{*}-T$ curve becomes normal to the T ordinate; that is, the susceptibility changes without a corresponding change in the absolute temperature. The sharp bend in the resistance curve II near 0·034° shows that our T^{*} is quite close to Simon's value for T at that point. Below the Curie point the discrepancy increases rapidly, since T^{*} changes without a corresponding change in T. The lowest T^{*} which we observed was 0·027°. The corrected resistance curve would probably show no bend near 0·034° such as is seen in Fig. 2.

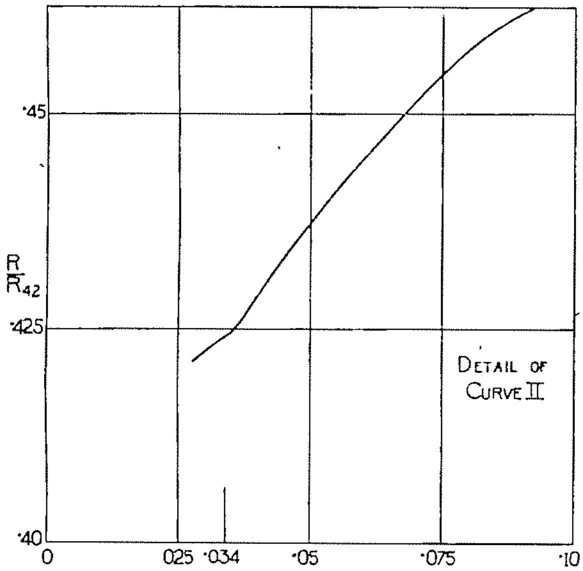

Fig. 2.

From the shape of the resistance curve it is impossible to say whether or not phosphor-bronze would become supraconducting below 0·034° K. The extreme structure sensitivity of phosphor-bronze with regard to resistance can be seen from Curves I and II, where the current densities are the same in both cases. Between taking Curves I and II the thermometer was rewound and leads were resoldered to it. Curves I, III and IV show the effect of changing the current density, and agree with results previously obtained by W. H. Keesom and van den Ende[3].

If the thermometer is left untouched, the temperature-resistance curves are reproducible to within the limits of experimental error. The thermometer may be repeatedly subjected to strong magnetic fields without affecting the calibration, provided the measurement of resistance is made in zero magnetic field. The results show that for a given specimen, a phosphor-bronze resistance thermometer can be quite conveniently used in the range of temperature below 1° K., and possesses approximately the same accuracy as does the ballistic measurement of susceptibility for the determination of T^{*}.

Positrons from Radio-Scandium

ACCORDING to Fermi's theory[1] for the emission of β-particles, and its modification by Konopinski and Uhlenbeck[2], a nucleus can, instead of emitting a positron, absorb an electron from the K-shell, thus giving rise to the emission of the K-radiation from the element formed by the transformation. The ratio of the probabilities F for the emission of a positron and F_K for the absorption of a K-electron has been calculated by Møller[3] and by Mercier[4]; for scandium ($Z = 21$), the value for F_K/F varies from 0·1 to 5 according to the assumptions made in the theory.

I have carried out experiments with radio-scandium to see if the emission of positrons is accompanied by the emission of the K-radiation of calcium. Radio-scandium was obtained by bombarding lime, supported on a mica leaf, with α-particles from 300 millicuries of radon. The mica leaf with the lime was placed at the centre of an expansion chamber and the tracks photographed with air in the chamber in a magnetic field of 700 gauss. About 500 tracks were photographed, of which about 250 were utilized for measurements. The distribution of energy is shown in Fig. 1; the accuracy in the energy measurements is only moderate due to the use of air in the chamber, but is sufficient to give the upper limit of energy as 1·1 ± 0·1 MeV.

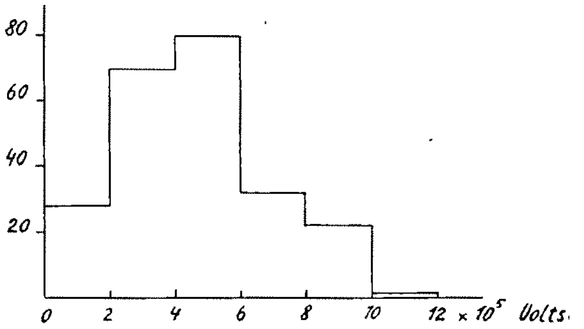

Fig. 1.

The K-radiation of calcium, when present, would by its absorption in the air of the chamber produce electrons with a range[5] of about 0·2 mm. This was checked by sending X-rays scattered from a target of calcium into the expansion chamber through a thin aluminium window. In the experiments with lime no trace of the X-radiation in question was observed; a number of short dense tracks was actually found, but these tracks were in nearly all cases secondaries from fast electrons and were further distributed uniformly throughout the chamber, whereas the X-radiation from calcium could only be found in one half of the chamber, since the mica leaf supporting the lime would absorb the X-radiation almost completely. The persistence of tracks with a high density of ions is larger than for tracks from fast electrons, so that the absence of K-radiation from calcium is fairly certain.

An estimate of the upper limit for the ratio F_K/F can be obtained from a consideration of the absorption of the K-radiation from calcium and the dimensions of the expansion chamber. In the absence of any observed effect such an estimate must necessarily be rather vague, but it appears fairly safe to assume that $F\ /F$ is less than $\frac{1}{10}$ and is probably less than $\frac{1}{100}$. The result of the present investigation, when compared with the calculations by Møller and by Mercier is, therefore, that Fermi's theory for β-decay is probably in accord with experiments; the modifications introduced by Konopinski and Uhlenbeck predict an emission of X-rays from elements emitting positrons, which is so intense relative to the emission of positrons, that it could scarcely have been overlooked in the experiments.

s-Trideuterobenzene and the Structure of Benzene

THE first and probably largest single step in the solution of the spectroscopic problem of the structure and vibrations of benzene was taken when, by comparison of the Raman and infra-red spectra of C_6H_6 and C_6D_6, the eleven active fundamental frequencies were identified, and shown to have isotope shifts agreeing with an application of Teller's theorem to the D_{6h} model[1]. It remained to determine the nine inactive frequencies, and secure the confirmation they should yield. For this purpose the plan outlined was to remove symmetry piecemeal by oriented deuteration in the sequence 1 : 3 : 5-$C_6H_3D_3$ (no centre), 1 : 4-$C_6H_4D_2$ (no 3-fold axis), C_6H_5D (no centre, no 3-fold axis), thus allowing previously inactive frequencies to become active a few at a time.

We have now completed the spectroscopic study of *s*-$C_6H_3D_3$, in which six additional fundamentals become allowed in either the Raman or infra-red spectrum. The centre of symmetry, which in C_6H_6 and C_6D_6 forbade coincidences, having now been destroyed, seven allowed fundamentals are common to the two spectra.

Having shown that the laws of electrophilic substitution are followed in the direct deuteration of aromatic compounds[2], we prepared the required benzene in a spectroscopically pure form by trideuterating aniline and eliminating the amino-group. Other methods had yielded spectroscopically impure material owing to partial randomization of the deuterium, a phenomenon which has been overlooked with resulting error in the published literature of partly deuterated benzenes.

We have determined the frequencies of forty lines in the Raman spectrum of the liquid, and the peak and integrated intensities and depolarization factors of eleven of them. We have measured also thirty-two infra-red absorption maxima for the vapour, and studied the contours of the twelve chief bands. The following abridged table contains the more prominent frequencies (cm.$^{-1}$).

Raman		Infra-red
E'' 375	‖	583 A_2''
E' 590·0	——	591 E'
E'' 707·5 D		691 —
E' 830 8	——	833 E'
A_1' 958 5 P	‖	914 A_2''
A_1' 1000 9 P		1065 —
— 1064		1095 E'
E' 1102 6		1226 —
E' 1407	——	1407 E'
E' 1572·2	——	1573 E'
— 2239 3		1631 —
A_1' 2279 0 P		1749 —
E' Obscured		1835 —
— 2975 7		2292 E'
A_1' 3053 8 P		2302 —
E' 3094	——	3087

The fundamentals are indicated by assignment symbols: A means totally symmetric, E degenerate, ′ and ″ symmetric and antisymmetric to the ring-plane, and $_1$ and $_2$ symmetric and antisymmetric to a 2-fold para-axis. The tie-lines show the allowed coincidences of fundamentals: in these the Raman lines are depolarized and the absorption bands perpendicular. The optical properties of the other fundamentals are shown by the symbols P = polarized, D = depolarized, ‖ = parallel. The assignments agree with these properties, and the frequencies satisfy Teller's theorem applied to the D_{3h} model.

The frequency, 1000·9, in which alternate ring-atoms move radially towards and from the centre, is inactive in C_6H_6, but we can now calculate that its frequency must be 1007, which is almost exactly what Kohlrausch[3] and also Lord and Andrews[4] estimated. The puckering vibration, 375, should also be inactive in C_6H_6, but its frequency supports Lord and Andrews's suggestion[4] that the weak Raman line, 404, of C_6H_6 arises from this vibration, which though forbidden appears on account of the intermolecular forces.

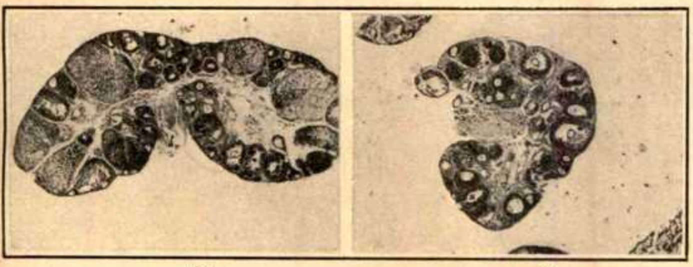
An Antiluteogenic Factor in the Anterior Pituitary

RECENTLY Evans[1] reported the existence of a new pituitary factor, the 'antagonist', which inhibits follicle development in infantile rats when simultaneously injected with follicle-stimulating extracts from various sources. To avoid misunderstanding, it is proposed to call this factor 'antifolliculogenic', in contrast with 'antiluteogenic'. At about the same time, Bunde and Greep[2] described a regression of persistent corpora lutea in the ovaries of hypophysectomized rats by the luteinizing fraction of pituitary extracts.

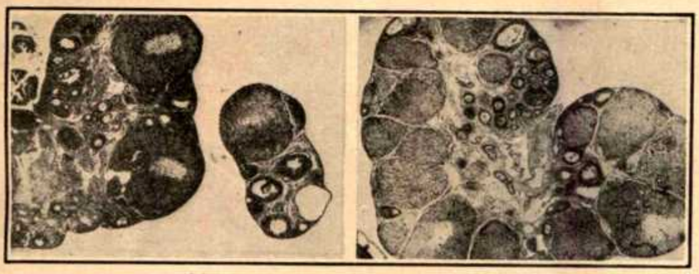
The failure of regression of corpora lutea in a few thousand hypophysectomized rats has been very consistently proved in this laboratory. However, quite exceptionally in adult animals, no corpora lutea were found, when between hypophysectomy and autopsy they were used for testing 'growth hormone'. Another observation with importance in this connexion is, that very often after the twelfth day following insemination the complete removal of the pituitary in rats does not interfere with pregnancy, otherwise than that delivery is delayed 2–3 days beyond term. The responsibility for this was ascribed to the persistence of corpora lutea and confirmed by the histological appearance of the ovaries and by death, maceration and compression of the fœtus or abortion when the ovaries or only the corpora lutea alone were removed even a few days before expected delivery. An antiluteogenic function of the pituitary was suspected on these grounds and further experimental evidence in favour of this view was obtained as follows.

An alkaline extract from an acetone dry powder of beef anterior pituitaries after subcutaneous injection in infantile (about 20–28 days old) rats weighing 25–35 gm. produces enlarged ovaries with four to eight corpora lutea each (Fig. 1, *a*). The same extract when given intraperitoneally produces little ovarian growth, a few follicles with antrum and no corpora lutea (Fig. 1, *b*). Subcutaneous injection of a pregnancy urine gonad-stimulating extract yields moderately enlarged ovaries with a few cystic follicles and four to eight corpora lutea on each side (Fig. 2, *a*). Combined injection of the urine extract and the pituitary extract both subcutaneously, yield much enlarged ovaries with twelve to twenty corpora lutea each (Fig. 2, *b*), while after simultaneous injection of the urine extract subcutaneously and the pituitary extract intraperitoneally small ovaries are found with a few (cystic) follicles but no corpora lutea (Fig. 3).



(*a*) (*b*)

Fig. 1.



(*a*) (*b*)

Fig. 2.

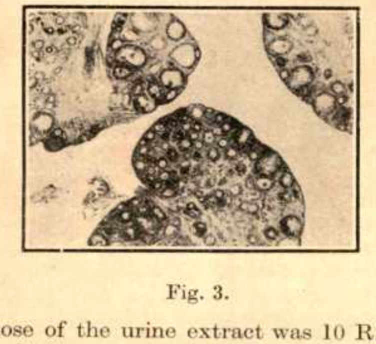


Fig. 3.

The dose of the urine extract was 10 R. œstr. U., of the pituitary extract 160 mgm. acetone dry powder extracted at *p*H 10·5. Six injections were given in 36 hours, the ovaries were removed for histological examination (hæmatoxylin-eosin staining) on the fifth day after the beginning of the experiment; four or five rats were used for every group and littermates were uniformly distributed. The experiments were repeated three times.

Confirmatory evidence was found by the interruption of two early (twelve day) pregnancies after eight intraperitoneal injections in five days. At autopsy no fœtuses were found. They probably were resorbed, because the placentæ were recovered in macerated condition from the uterine horns.

Oxygen Evolved by Isolated Chloroplasts

THE high affinity for oxygen possessed by muscle hæmoglobin suggested its use as a very sensitive spectroscopic method for detecting and measuring small quantities of oxygen[1]. This method has now been applied to study the oxygen evolution of isolated chloroplasts exposed to light. While being much less sensitive than the bacterial methods which have been successfully applied in the past, the hæmoglobin method (originally used by Hoppe-Seyler to demonstrate oxygen from green plants) has the advantage of giving the measure of oxygen. A solution of hæmoglobin containing $0{\cdot}45 \times 10^{-4}$ gm. atoms of iron per litre, is equivalent to 1 c.mm. of oxygen per c.c.; the degree of saturation can be determined spectroscopically with an accuracy of 5 per cent.

Fresh suspensions of chloroplasts obtained from various angiosperms with sucrose solutions do not evolve measurable amounts of oxygen in the light, even in presence of carbon dioxide. If, however, chloroplasts were suspended in an aqueous extract made from an acetone-leaf preparation, oxygen in measurable amounts was evolved in light. Extracts of acetone yeast or boiled yeast would produce the same effect as the leaf extract. The activity of these preparations depended on their ferric iron content, and they could be replaced by ferric potassium oxalate. Molecular oxygen is evolved, while ferric iron is reduced to ferrous.

At the beginning of the experiment oxygen is rapidly evolved, but as the partial pressure of oxygen rises the oxygen is absorbed and its evolution comes to a stop. This shows certain advantages of the hæmoglobin method over a manometric method, which could not be applied in the present case. A strong illumination of approximately 40,000 lux was used. The chloroplasts were present in an amount equivalent to $0{\cdot}2 \times 10^{-4}$ molar chlorophyll. The vessel was an evacuated Thunberg tube, 1·5 cm. diameter and containing 5 c.c. of fluid. Oxygen output curves in terms of percentage saturation of the hæmoglobin with oxygen are shown in Fig. 1 for (*A*) chloroplasts in leaf extract, (*B*) chloroplasts in an extract of boiled yeast, (*C*) and (*D*) chloroplasts in ferric potassium oxalate, all at 20° C. The evolution of oxygen in presence of ferric salts was not influenced by concentrations of sodium azide and hydroxylamine which markedly inhibit catalase.

The iron-oxygen reaction of chloroplasts may indicate a mechanism connected with carbon assimilation. The appearance of molecular oxygen in light from a biological system apart from the whole cell or from hydrogen peroxide and catalase is unique. There is no evidence, however, that this particular reaction takes place in the living cell, neither is it proved that carbon dioxide takes part in the reaction. Carbon dioxide is the only known reagent which will cause oxygen evolution by the living plant ; ferric iron at present seems to be the only reagent which will cause measurable oxygen evolutions by free chloroplasts. This may be connected with the very interesting specific *in vitro* reaction found by Rabinowitch and Weiss[2] with ethyl chlorophyllide and ferric chloride, where the chlorophyll derivative appears to be reversibly oxidized in light while the iron is reduced.

Until other facts have been definitely established, it might be misleading to discuss the different theories of photosynthesis involving iron salts. The fact, however, that molecular oxygen in measurable quantities can be evolved by a biological system, less organized than the whole cell, gives new possibilities for applying biochemical methods to the green plant.

Commensalism between a Marine Mussel, an Anemone and several other Organisms

ON February 4, 1937, Mr. A. R. Holland, assisting us in biochemical investigations on the California mussel, *Mytilus californianus*, brought to our attention one individual which showed a fair-sized cup or raised crater, built of the same calcareous material as constitutes the shell, attached at its base to the anterior region of the inside of the left valve, protruding through the mantle into the gill chamber, and containing a number of commensal invertebrates and some attached plant material.

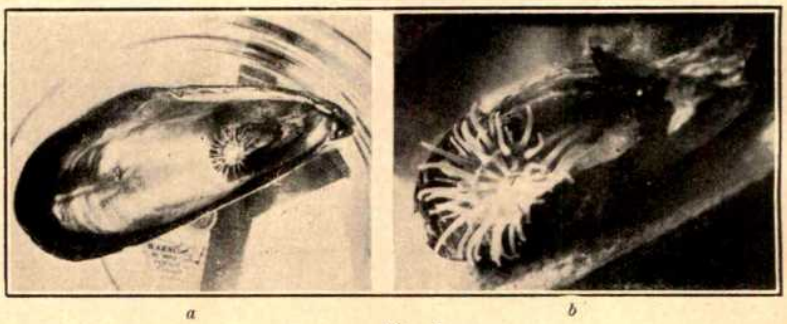

Fig. 1.

LEFT VALVE OF MUSSEL WITH FLESH REMOVED. (*a*) WHOLE VALVE ; (*b*) ENLARGED VIEW OF CRATER CONTAINING ANEMONE.

Most striking among the commensal animals was a small anemone, attached to the inside of the crater, with disk and spread tentacles extending over the rim of the crater into the gill chamber (Fig. 1). Other organisms found in the crater were a small bivalve mollusc, several polychæte worms, numerous Protozoa, a large siphonaceous alga apparently of the genus *Derbesia* and some small filaments of Myxophyceæ, along with much detritus. For the information regarding the algal organisms we are indebted to Prof. N. L. Gardner, of the Department of Botany at the University of California, to whom we submitted the plant material.

The mussel was a healthy female containing masses of orange-coloured eggs in its mantle ; the shell is 11·5 cm. long ; the crater 3·5 cm. long, 1·7 cm. wide (outside diameter at widest portion), and 1·2 cm. in depth, its bottom being the bright, nacreous inner surface of the valve.

The anemone was also healthy, ready to feed, and is still living (March 18) in the crater ; it showed a pale greenish ring around the oral aperture, the tentacles being only very faintly greenish in tint. Zoochlorellæ were not observed. The animal is almost certainly a young specimen of our common anemone *Cribrina* (= *Bunodactis*) *xanthogrammica*. It showed, at the time of discovery, a tentacle spread of 2 cm., the diameter of the oral disk being 0·8–0·9 cm.

Where the mantle surrounded the outer wall of the crater's short column, it was attached thereto, and had formed a dark out-curling lip around the edge of the crater's opening; this lip was composed of a chitinous material similar to that which is laid down by the mantle at the inner rim of each valve.

Prof. G. E. MacGinitie, at the Kerckhoff Marine Biological Laboratories of the California Institute of Technology, writes (personal communication) that he has encountered such craters as described above in certain other lamellibranchs, notably *Schizothærus*, but that the condition is rather rare. He states that such pockets, built up by the animals in response to the presence of insoluble detritus which may lodge between the mantle and the shell, will soon become inhabited by other forms which invade it in larval stages, and that it is a matter of relative chance what forms adapted to such a locality first secure residence. The laws governing survival then determine which members of such a group may retain their places and which must be crowded out or devoured.

The subject of commensal organisms encountered within lamellibranch shells is rather extensive, and has no place in this note. It seemed of interest, however, to report this particular case, since a fair search through the literature and discussions with various ecologists failed to reveal previous reports of commensalism between a normal anemone and a healthy, plankton-feeding lamellibranch.

Water and Fat Content of Tsetse Flies

IN recent letters Mr. R. W. Jack[1] and Dr. C. H. N. Jackson[2] state that, when considering the effects of climate on tsetse metabolism, it is valuable to express the percentage of water present in the insects at different times as a function of the "fat-free" dry weight. This is because the amounts of this food-reserve vary greatly; it occurs concentrated in the fat-body and not in large amounts in the individual cells of the vital tissues. Jack and Jackson imply that their methods show the conditions in the tissues of the tsetse more accurately than do gross percentages of water and dry matter present in the bodies of the insects.

I am doubtful whether this manipulation of the results is really useful. If we wish to know what conditions obtain in the tissues, it will be necessary to study individual tissues by microanalytical methods. There are many constituents of an insect's body which vary greatly, such as skeletal structures, gut-contents or fæcal materials, and they, as well as fat, should be subtracted to obtain the sort of results which Jack and Jackson desire. There is one other substance which they do not consider, but which should be studied in investigations of the water-balance of insects, and that is the circulating fluid or hæmolymph. Dissections of bedbugs, ***Rhodnius***, tsetse flies and other insects show that sometimes the tissues are amply bathed with fluid, while at other times they appear almost dry. The hæmolymph acts as a sort of 'buffer' against desiccation. The tissues themselves do not usually appear to vary greatly in water-content, for so long as there is a sufficient supply of hæmolymph to circulate, the cells of the various organs reached by it are not themselves desiccated unduly. This has been shown experimentally by analyses, by microscopic examination of the living tissues themselves, and the same conclusion is supported by Wigglesworth's observations[4] on the extent of the fluid in the tracheoles of desiccated insects. These changes in volume of the circulating fluid will affect the gross analyses enormously, whether or not the fat is subtracted.

These comments are made because I feel that if other workers adopt Jack's and Jackson's suggestions, they may be diverted from more significant studies of the effects of climatic conditions on vital structures. Laboratory studies[3] show that the gross percentage of water in a tsetse fly may vary more widely than Jack's and Jackson's field observations indicate, without the insect being harmed or its metabolic rate being affected. The insects have to lose a great deal of water, probably equivalent to the whole of their hæmolymph, before they suffer from desiccation. Normally, even under dry conditions, they appear to exhaust their reserves of fat before this happens; or they obtain a meal of blood which contains sufficient excess of water to allow the body to return to normal.

Histology of *Derris* Roots

WE have recently investigated the histology of *Derris elliptica* roots, with respect to their contents of rotenone and related toxic substances. Cells which apparently contain resins are distinguishable in unstained sections. We have applied Durham's test to sections, and have shown that the resin cells, and these only, respond to the test.

Rotenone cells first appear in young roots just as suberization is beginning, but never before, as isolated groups in the secondary cortex. These are invariably arranged opposite to the protoxylem elements, and correspond in number to them. Rotenone afterwards appears in cells scattered through the xylem parenchyma and the cortex. These increase in number with the age of the root, and are especially numerous in the medullary rays. They appear to be structurally non-specialized, and are indistinguishable from normal xylem parenchyma.

Starch also occurs in *Derris* roots. It is mainly confined to the semi-lignified cells forming a sheath to the vessels, but it also occurs in scattered irregular groups in the non-lignified xylem parenchyma and in the cortex. We have never observed starch and rotenone in the same cell: in fact, we are satisfied that, in the xylem parenchyma, starch cells and rotenone cells form mutually exclusive groups.

A paper giving the full results of this investigation is being prepared for publication.

Estimation of Ammonia Volatilized from Soils

ALTHOUGH it has been recognized that a part of the nitrogen in the soil system may be lost in the form of ammonia, the extent of such loss—especially under field conditions—has not yet been satisfactorily determined, largely owing to want of suitable technique. Estimates based on difference in total nitrogen are not sufficiently accurate. Aeration methods are tedious and time consuming: they also disturb the biological conditions in the medium. Extraction and distillation methods are unsuitable, as the estimates thus obtained may not be entirely due to free ammonia. The following method was therefore developed, and was found to work quite satisfactorily.

The procedure consists in pasting a piece of filter paper (previously acid treated, for example, Whatman No. 30 or 41) moistened with standard acid on the inside of a glass or enamelled dish which just covers the beaker or other vessel containing the soil. The ammonia evolved from the medium is absorbed by the acid. At convenient intervals the dish can be removed and the unused acid in the paper estimated by back titration against standard alkali with methyl red as indicator and boiling to drive off carbon dioxide.

The above procedure is very simple and rapid. By suitably altering the strength of acid, varying quantities of ammonia can be estimated. The method can be applied to time studies, the paper being changed periodically. The temperature can also be varied according to requirements. The studies can be carried out under both laboratory and field conditions.

Applying the above method, it has been found that practically all soils treated with ammoniacal fertilizers—especially under tropical conditions—lose ammonia by volatilization. In some cases, all the added nitrogen is lost in the course of ten days. Soil treated with organic manures with narrow C—N ratios also lose large quantities of nitrogen as ammonia.

The mechanism of the related processes has been studied and will be reported elsewhere.

The So-called 'Transition Temperature' of Metallic Films

THE relation of the electric resistance to temperature of metallic films of zinc, cadmium, magnesium and antimony, condensed from vapours on a cold surface of glass, was investigated employing an apparatus similar to that described in a previous paper[1]. A double-walled copper cylinder was inserted in the inner vessel in order to cool pentane contained in the latter indirectly with liquid nitrogen, and a stirrer was used to ensure uniformity of temperature distribution. The bath temperature was read with a copper-constantan thermo-junction and a millivoltmeter, and the thicknesses of the metallic films were estimated by weighing with a microbalance having an accuracy of 1×10^{-5} gm. The metallic specimens were from Kahlbaum.

Zinc, cadmium and magnesium were condensed on glass at − 150° C. and antimony at − 75° C., and the heating rates were kept between 1·0° ~ 1·2° C. per minute. An example of the changes of resistance for various thicknesses of films is shown in Fig. 1. The so-called 'transition temperature'[2], which is the crystallizing temperature, is indicated by arrows, and becomes less distinct when the thicknesses of the films reach several hundreds millimicrons. Abrupt increases of resistance in zinc, cadmium and magnesium are caused from the crack-formation in the films.

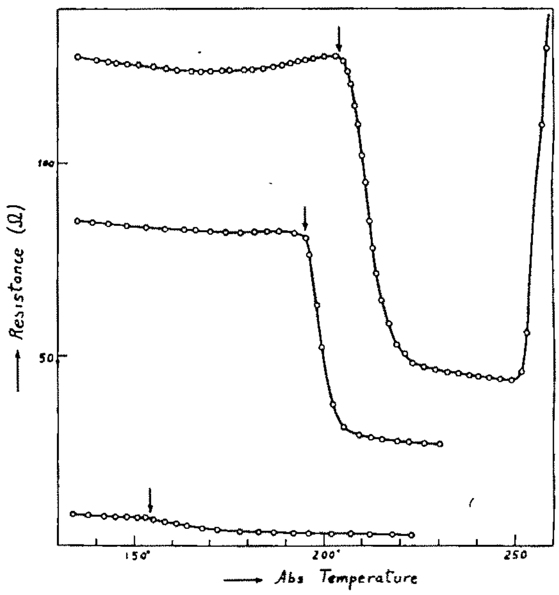

Fig. 1.

RESISTANCE OF CADMIUM FILMS.

If the films are not too thin, linear relations exist between the thicknesses and the logarithm of the transition temperatures. The gradients of these straight lines are exactly the same for zinc and cadmium, and almost the same for antimony and magnesium. When this straight line relation is extrapolated to zero thickness, the ratio of transition temperature (Tu) to melting point (Ts) of the respective metals ranges from 0·36 to 0·41, which coincides with that for the bulk metals[3] as shown in the following table:

	Zinc	Cadmium	Magnesium	Antimony
$\log_e t_u$	5 625	5 485	5 8	5 82
t_u	277°	241°	330°	337°
t_s	692°	594°	906°	903°
t_u/T_s	0 40	0 41	0 36	0 37

The present investigation is being extended to other metals.

Dispersion of Sound Velocity in Liquids

As is now well known[1], the spectral character of monochromatic light scattered by many liquids exhibits an observable change as the result of such scattering; an instrument of sufficiently high resolving power, for example, a Fabry-Perot étalon[2], indicates the presence of Doppler-shifted components on either side of the main radiation. From this we are able to infer that sound waves of very high frequency represent a considerable part of the energy of thermal agitation in such liquids. The frequency of the sound-waves actually revealed by this method depends on the wave-length of the incident light, the angle of scattering and the liquid employed; in most actual cases, it lies within the frequency range 1,000–10,000 megacycles per second.

It is a question of considerable importance, whether these spontaneously existing sound-waves of thermal origin of very high frequencies ('hyper-sonic waves'), have velocities of propagation differing appreciably from those of lower frequencies (audio-waves and ultra-sonic waves) capable of being produced artificially by mechanical or electro-acoustic methods. The sound velocities within the ultra-sonic range (< 100 mega-cycles) can be measured with high precision (Hiedemann[3] and Parthasarathy[4], etc.). For the determination of the hypersonic velocity, we have to depend on the magnitude of the Doppler-shifts as observed interferometrically, the measurements of which are, however, liable to serious errors owing to (*a*) the angular width of the scattered beam, (*b*) the intrinsic breadth of the Doppler component, and (*c*) the imperfect monochromatism of the incident radiation, including especially the hyperfine structure satellites. The third source of error is particularly serious, as the satellites are intense and by their superposition shift the apparent position of the Doppler components. An examination of the published literature shows that none of the measurements reported so far has taken account of the sources of error sufficiently to enable any definite conclusions to be drawn from them.

TABLE 1.

Liquid	Observed Doppler shift (cm.$^{-1}$)	Velocity in metres/second	
		'Hyper-sonic' frequency 5 0 × 10^9	'Ultra-sonic' frequency 7 32 × 10^6
Carbon tetrachloride	0 261	1070 ± 25	928 ± 1
Acetone	0 221	978 ± 25	1205 ± 1

The subject has been taken up afresh by me, at the suggestion of Sir C. V. Raman, and systematic efforts have been made to eliminate the sources of error mentioned above by choosing the experimental conditions suitably. By using a low-density and cathode-cooled mercury arc lamp, and by a proper selection of the radiation used and of the invar distance piece separating the plates of the étalon employed, with reference to the sound velocity in the liquid under investigation, it has been found possible to eliminate the errors and obtain dependable results.

The programme now on hand includes numerous liquids; it will be sufficient here to report the results for carbon tetrachloride and acetone, which have stood the test of careful repetition and scrutiny.

It is interesting to note that in carbon tetrachloride the hyper-sonic velocity is definitely greater than the ultra-sonic velocity, while in acetone the reverse is the case.

An Effect of Rectified Current from a Tunger Valve upon the Electrolytic Separation of Heavy Water

A RATHER low yield of the heavy water obtained with the usual method of electrolysis, using the single-phase full-wave Tunger valve rectifier, led us to investigate the cause of loss of the heavy water. Besides a good deal of loss through evaporation and spraying, and possibly a loss arising from an exchange reaction occurring at the electrode, the rectified current employed may have been also a contributing factor to the loss.

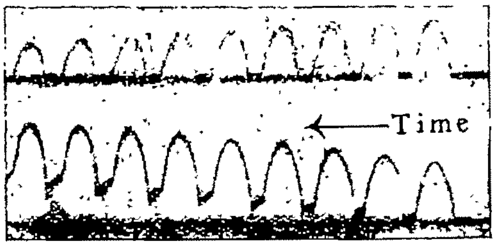

Fig. 1.

With this latter view in mind, the following experiments were performed. Two identical cells in a closed form with nickel electrodes, which were so constructed as to make a loss from evaporation and spraying entirely negligible, were employed. In each of these two cells was placed an equal amount of the electrolytes (40 c.c.) with 1 per cent D_2O content. To one cell was supplied the direct current, to the other the rectified current. The two cells were independently connected with a Wood discharge tube. The intensity of the Dγ line in the Balmer series was observed from the water remaining in the cell, simultaneously with the decrease of the volume of the electrolyte. The result after the exposure of one minute showed that on the D.C. side the Dγ line appeared at one ninth the initial volume, whereas on the rectified current side the same intensity of Dγ line appeared at one twenty-seventh the initial volume.

The effect was also investigated with the oscillograph, using this time fifteen cells actually employed for the production of the heavy water. The result showing the variation of current and voltage with the time immediately after the rectified current was supplied are shown in Fig. 1, where *a* shows that the current passing through the cell becomes smaller with the period of the pause becoming greater; and *b* shows that the back E.M.F. reaches the half-value of saturation in 10/120 sec., during which a H atom may be able to stay on the electrode.

The action at the cathode may be as follows: first, neutralization of the hydrogen ion or its hydrated ion with an electron from the cathode metal, and secondly, recombination of H atoms to form a molecule. Both H and D atoms accumulated at the cathode tend to diffuse back into the solution during the pauses of *a*, but their respective rates will be different. According to the theories of W. R. Gurney[1] and R. P. Bell[2], the rate of diffusion of an atom into the solution depends on the force constant of the link between the ion and the water molecule. With the increase of atomic weights, the force constant of the link or the heat of hydration becomes smaller, that is, the rate of the diffusion becomes smaller; thus, for example, the heat of hydration of H ion is 200 kcal. per gm.mol., while that of Li ion 15 kcal. per gm.mol. Therefore, the rate of back diffusion of the H atom will be higher than that of the D atom. Consequently, D may remain on the electrode sufficiently long for another D or H atom to approach it, with the formation of D_2 or HD, which will escape as a gas molecule. This process may perhaps account for a loss of D content during the electrolysis, in our case.

A New Alloy of High Density

IN an article in NATURE of March 20[1], Dr. C. J. Smithells describes a very interesting method of producing alloys of tungsten without melting the tungsten itself. He mixes tungsten powder together with copper and nickel powder and then heats them to 1,450° C., at which temperature the mixture sinters, the tungsten becoming embedded in a tungsten-copper-nickel eutectic. He thus avoids the technically extremely difficult, if not impossible, task of heating large masses of tungsten to melting point.

This metallurgical process is of particular historical interest, as it makes use of the principle employed by the Pre-columbian Indians of the Esmeraldas coast in South America. As I have shown[2,3], these Indians used the above method to produce coherent platinum; the platinum was heated together with a small quantity of gold until the melting point of the latter was reached. The platinum thus became embedded in a platinum-gold eutectic. Subsequent alternate heating and hammering produced a homogeneous alloy so resembling ordinary platinum that superficial examination will deceive even a modern metallurgist.

Effect of the Penetration of X-Rays on the Resolving Power

FROM the generality of the principle of uncertainty $\Delta E.\Delta t = h$, it follows that the equation for the resolving power of a grating $\lambda/d\lambda = m.n$ (where λ is wave-length, m is number of rulings, n is order of the spectrum) is valid not only for the ruled grating, but also for space-lattices. On the other hand, for example, for the ruled plane gratings used for X-rays, the resolving power is limited by the fact that it is not possible to collimate the reflected beam of X-rays. It can be shown that for the space lattices also the resolving power is limited, owing to the widening of the lines caused by the penetration of X-rays into the crystal, since the reflected beam of width w_0 is not collimated (see Fig. 1), so that the resolving power, corresponding to the number m of reflecting planes, cannot be attained.

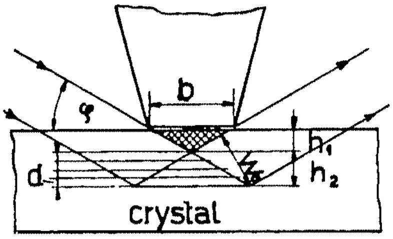

Fig. 1.

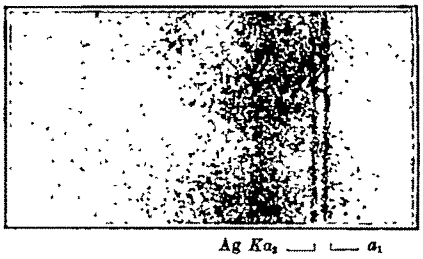

Fig. 2.

We attempted to find the effective depth of penetration of the radiation into the crystal using the Seemann 'edge' method, only instead of sharp edges we used blunt edges of various thicknesses b, placed against the surface of the crystal. Thus, as shown in Fig. 1, we screened from the incident X-rays of glancing angle φ a surface portion (though mostly effective) of the crystal to the depth $h_1 = \tan\varphi.b$.

We used the $K\alpha$ lines of silver. By using an edge of thickness $b = 0{\cdot}3$ mm. pressed against the surface of the crystal, we have screened (for silver $K\alpha$, calcite crystal $\varphi = 5° 20'$), a depth $h_1 = 1{\cdot}5 \times 10^{-2}$ mm. With this arrangement we obtained the photograph shown in Fig. 2. Comparing this result with those obtained by means of sharp edges for this region of shorter wave-lengths[1], it can be seen that by screening a definite depth of the crystal, and thus diminishing the number of reflecting planes, the resolving power has been considerably increased (about five times).

From the width of the silver $K\alpha$ lines on plates taken at varying distances from the crystal, and by measuring the divergence of the beam $\Delta\varphi = 11''$, we have calculated the width w_0. This width corresponds to the depth h_2, which remains effective for interference in the crystal after screening $h_2 = 2 \times 10^{-2}$ mm.

The decreased number of reflecting planes corresponding to this depth h_2 is thus still of a greater order than that corresponding to the resolving power $\lambda/d\lambda = m.n$ actually obtained, so that the resolving power is still not limited by the time uncertainty Δt between rays reflected from the first and m-th planes. On the other hand, it can be shown from the results of Allison and Parratt[2], that the limiting of $\lambda/\Delta\lambda$ by Δt occurs for long wave-lengths, for example, for Si *Kα*.

By using the screening method described above also for the *Kα* lines of copper, we found that the resolving power for these lines was increased, if compared with that obtained by us without screening, but was not greater than that obtainable from a vacuum spectrograph using the Bragg method.

Points from Foregoing Letters

RESISTANCE-TEMPERATURE curves have been obtained by Dr. J. F. Allen and E. S. Shire for a phosphor-bronze resistance thermometer down to a susceptibility temperature of 0·027°. The results show that a phosphor-bronze resistance thermometer can be conveniently used in the range of temperature below 1° K. From Simon's relation the probable difference between susceptibility temperature and the absolute temperature at such very low temperatures is not greater than 0·02°.

The energy distribution of positrons emitted by radio-scandium, produced by irradiating lime with alpha particles from radon, has been determined by Dr. J. C. Jacobsen. He finds that there is no emission of X-rays corresponding to the *K*-radiation of calcium, as would be expected from the hypothesis of Konopinski and Uhlenbeck.

As a further step in the spectroscopic investigation of the structure and vibrations of the benzene molecule, a table giving the more prominent frequencies in the Raman spectrum of *s*-trideuterobenzene (s-$C_6H_3D_3$) is submitted by a group of investigators from University College, London.

When the pituitary glands are removed from rats, the corpora lutea do not regress in the usual way, but persist. This, J. Freud points out, suggests the presence of an antiluteogenic factor in the pituitary, and he finds further support for this view in the fact that when an extract of the anterior pituitary is injected intraperitoneally in infantile rats, the formation of corpora lutea is inhibited. Subcutaneous injections, on the other hand, do not prevent the formation of corpora lutea.

The evolution of oxygen from illuminated chloroplasts isolated from the cell has been measured spectroscopically by the use of hæmoglobin by R. Hill, who finds that the evolution of oxygen is caused not by carbon dioxide, as in the intact cell, but by ferric salts which become reduced to ferrous salts while molecular oxygen is liberated.

Dr. K. Mellanby does not consider that expressing the content of water in tsetse flies as a function of the fat-free dry weight gives an accurate picture of conditions in the tissues, as is suggested in recent letters by R. W. Jack and C. H. N. Jackson. Gross changes in the volume of circulating hæmolymph occur, considerably altering the dry-matter water ratio. The tissues themselves are not desiccated so long as any circulating fluid remains.

Prof. V. Subrahmanyan directs attention to loss of soil nitrogen by volatilization of ammonia and describes a method for estimating it. The ammonia is absorbed in filter paper previously moistened with known quantities of standard acid. Applications of the method are indicated.

A table giving a comparison of the velocity of ultra-sonic waves (of frequency 7×10^6) in carbon tetrachloride, and also in acetone, with the velocity of 'hyper-sonic' waves (of frequency 5×10^9) as deduced from new measurements of the Doppler shift in the monochromatic light scattered by those liquids, is submitted by B. V. Raghavendra Rao. In carbon tetrachloride, the hyper-sonic velocity is greater than the ultra-sonic while in acetone the opposite is the case.

A comparison of the increase in the concentration of heavy water by electrolysis, (*a*) with direct current, (*b*) with current rectified with a 'Tunger' valve, shows that the direct current is more efficient for separating the heavy water. From the shape of the current-voltage curves of the rectified current (analysed by means of the oscillograph), T. Asada and E. Honde infer that the loss in the heavy component produced by the rectified current may be due to the fact that the rate of diffusion of the heavy hydrogen (deuterium) being slower than that of the light hydrogen, a deuterium atom may remain on the electrode sufficiently long for another atom to approach it, with the resultant formation of D_2 or HD molecules, which then escape as gas.

Curves giving the electrical resistance at different temperatures of very thin metallic (cadmium) films condensed on glass are submitted by T. Fukuroi. The curves show a fall in resistance at the 'transition temperature'—which itself depends on the thickness of the film. The author gives a table indicating that in the case of films of zinc, cadmium, magnesium and antimony, the transition temperature is a constant fraction of their melting point.

By screening a calcite crystal to a definite depth by means of a blunt 'Seemann edge', Prof. V. Dolejšek and J. Klein find that the resolving power for the *K*-α lines of silver is increased about five times. From the generality of the principle of uncertainty they deduce that, as in the case of the ruled gratings, the resolving power of the space lattice of crystals is limited owing to the widening of the lines caused by the penetration of the X-rays into the crystal.

Military Organization in Swaziland

IN a study of the military organization of the Swazi (*Africa*, 10, 1, 2), Hilda Beemer points out that the one service which the military organization is no longer allowed to perform is the key to its former importance and present impotence. Inter-tribal warfare has been suppressed, and for the purpose of war against the European its weapons are out of date. Wars were waged to extend the boundaries, to retain tribal independence, and to secure internal solidarity. At times it was a competition instituted by the warriors to show their courage, loyalty and strength. The prize was glory and booty, more especially cattle. The young bloods would boast to the king, asking to be allowed to show that they were better than such and such a regiment, who would then ask permission of the king to be allowed to show their prowess against an outside enemy. An enemy rich in cattle would be chosen, and the tribal war-doctor would doctor the regiments to bring them home alive and 'wipe out' the terror of taking life. This was a national and not a personal rite ; and the individual soldier would often arm himself with powerful medicine purchased from private doctors. The king himself never went to war but while the regiments were away he, with the national war doctor, worked out destructive magic against the enemy, and in this way also fortified his own subjects. The old war magic was in the hands of a special clan who were forbidden to use it for private individuals or for civil strife between two sections of the Swazi. The tribal ancestors were always considered to be present in spirit, giving courage to the men and ennobling their aim. Spoil brought back was distributed by the king according to group and individual achievement. A certain number of cattle was always set aside for national use in the cattle posts of the king, while every man who killed an enemy was entitled to a decoration for bravery.

Clowns in Hopi Ceremonial Dances

DR. ELSIE CLEWS PARSON has edited the voluminous journals kept by Alexander M. Stephen, who from 1881 until the early 'nineties, when he died, was in touch with the Hopi of Arizona, and assisted J. W. Fewkes by his intimate knowledge of Hopi ceremonial and custom in the studies which the latter published with the Bureau of Ethnology (*Columbia Univ. Contrib. Anthrop.*, 23, Pts. 1–2). Stephen was admitted to three societies, the Flute, the Lalakon and the Snake, and he lived in several households, both Hopi and Tewa, on the Mesa top. His journals contain much detail unpublished even in the parts incorporated by Fewkes. Little attention is given to material culture (though an exception is his account of pigments, and their relation to sexual attribution and the cardinal points), and his observations deal mainly with the seasonal festivals, of which he took detailed notes while they were being performed. Owing to the changes which have since taken place and the reticence of the Hopi, which even Stephen found a hindrance, the material is especially valuable. One of the remarkable features which Stephen observed is the puzzling ceremonial of the clowns. Of this he gives a graphic description. On First Mesa there are four clown types, of which the Ta'chukti, like the Koye'mshi, wear masks with knobs and carry a fawn skin bag. They wear the black dress of a woman as breech-clout, and mask and body are painted with pinkish clay. They sing Zuñi songs, pretend to talk Zuñi and even make Zuñi prayer sticks. Their origin myth is a Koye'mshi brother-sister incest story, their play obscene or phallic, and their games are those of the Koye'mshi. They are sprinkled with meal as sacred figures and rain-making is an attribute of their eponymous spirit. They have no fixed chieftainship or organization. The Chuʳku'wimkya wear a wig and are painted yellow with red stripes across their faces. They initiate in an ash house, an outline in ash made in the dance court. The initiation is for temporary membership only, and seems to be part of their play. The ash house appears in the clown ritual elsewhere.

Nemertea and Crinoidea of the John Murray Expedition

NUMBERS 3 and 4 of the "Scientific Reports of the John Murray Expedition 1933–34" (British Museum (Natural History), 4 ; 1936) contain the Nemertea by J. F. G. Wheeler and the Crinoidea by Austin H. Clark. Only two specimens of nemerteans were collected by the Expedition, a littoral form taken with the dredge in shallow water off the Arabian coast which proved to be *Amphiporus reticulatus* Burger, previously only known from the Bay of Naples ; and a pelagic form sorted from the plankton taken in the Indian Ocean, representing a new genus and species which is described in the report under the name of *Nannonemertes indica*. This new nemertean is referred to the family Pelagonemertidæ, Mosley. The crinoids form an important addition to our knowledge of the fauna of the Indian Ocean, as they were very imperfectly known in this region, the sixteen species recorded enabling the author to supplement the information already available and to describe one new genus and five new species. An annotated list of all crinoids at present known from the seas west of Ceylon and the west coast of India is given and the crinoid fauna of the Indian Ocean and the Red and Arabian Seas is discussed. Many interesting points arise and for the first time it has been possible to describe, "with the probability of a reasonable degree of accuracy", the faunal relationships of the different portions of the Indian Ocean.

The Asteroid Nervous System

To Johannes Müller (1850) we owe the first recognition of the asteroid nervous system. As a result of subsequent work, it is widely taught that it is composed of three parts, a sensory ectoneural system, a hyponeural system (Lange's nerve) and an apical system, the two latter being motor in function and of mesodermal origin. The whole problem of this system has been re-investigated by J. E. Smith (*Phil. Trans. Roy. Soc.*, B, 227, 1937). The work was mainly based on *Marthasterias glacialis*, but six other species were also studied. It is suggested that a more useful division would be into sensory and motor systems. There is a general ectodermal sensory system with concentrations in the radial nerves and the circumoral ring found in all classes. The ring, however, is absent in Crinoids, which have a well-developed apical sensory system not homologous with the apical nerve of Asteroids, which is motor. The ectodermal system communicates with the motor system through the interspaces of the boundary zone of connective tissue. The hyponeural (motor) system is also a constant feature but the extent and position of its development are related to the type of motor activity of the animal. Thus in Echinoids, where a test prevents movement of the body wall, the radial hyponeural nerve is absent.

Fowl-Pox and its Transmission

FOWL-POX is a virus disease which attacks chicken, pigeons, geese, turkeys and other birds, and causes considerable loss to the poultry farmer. It appears as cheesy diphtheritic membranes in the mouth, and as warty growths on the comb, wattles and mucous membrane of the mouth and eyelid. In the past, it was supposed that these various lesions were caused by different agents, but R. L. Kaura and S. G. Iyer confirm the present view that all are due to a single filter-passing virus (*Indian J. Vet. Sci. and Animal Husbandry*, 6, Pt. iv, 313 ; 1936). They find that diphtheritic lesions from the mouth produce the fowl-pox lesions on the skin, and that the Indian strain of virus is immunologically indistinguishable from the English Weybridge strain. A. L. Brody has studied the transmission of the disease (Cornell Univ. Agric. Expt. Station, Memoir 195. Ithaca, N.Y., 1936). Direct contact is one certain method by which fowl-pox is spread within a flock, and contaminated inanimate objects may possibly do so as the virus on them remains alive for at least six weeks. Mosquitoes, such as *Aedes ægypti*, may also transmit the contagion by intermittent feeding. Inoculation of the bodies of mites (*L. sylviarum*) four days after their last association with diseased birds produced pox, but mites after feeding on diseased, and then on healthy, birds did not cause pox.

Pruning the Tea Plant

J. R. TUBBS (*J. Pom. and Hort. Sci.*, 14 (4), 317 ; 1937) has estimated that the young shoots of the tea plant (*Camellia Thea*), of which the majority of leaves are normally harvested almost as fast as they grow, have produced at the time of harvesting only half the amount of carbohydrate used up in their development. The consequent continual depletion of he reserves of the bush frequently causes die-back of branches, followed by fungal attack and the death of the whole bush. An investigation on plantations at 200 ft., 1,500 ft. and 4,600 ft. above sea-level howed that die-back was more common at the lower levations, and smaller amounts of reserve carbohydrate were found in the roots. Several methods of pruning were tried, and it was found that by llowing a number of branches to retain their foliage, method designated 'lung-pruning', the drain on carbohydrate was checked and the incidence of die-back reduced.

uchromocentre Type of Nucleus and Feulgen's Stain

IT is now commonly recognized that plant nuclei are usually either of the large chromosome type giving chromatin 'reticulum' in the resting stage or of he small chromosome type in which, in the resting tage, the small amount of chromatin is present in he form of euchromocentres lying peripherally to a large central region containing the single large nucleolus. G. Yamaha and S. Suematsu (*Sci. Rep. Tokyo Bunrika Daigaku*, 3, Section B ; 1936) have examined many species of Cucurbitaceous plants, which with *Impatiens* and *Ricinus* have the latter type of nucleus, and have followed the behaviour of the constituent parts of the nucleus to Feulgen's stain through the nuclear cycle. During prophase, in addition to the euchromocentres, the nucleolus and nuclear sap also stain faintly with Feulgen. At metaphase-anaphase the chromosomes are fully chromatic, but the nucleolus, which persists to this time, and the nuclear sap no longer stain. After the formation of the nuclear membrane at the completion of telophase, a clump of irregular granules, often in connexion with the disappearing chromosomes, appears and afterwards this clump rounds off to form the typical nucleolus of the resting stage. There seems strong evidence in this case that material responsible for the Feulgen reaction is, at least in part, transferred from nucleolus and sap to chromosomes during prophase and from chromosomes to the sap and a new nucleolus at telophase.

Air-Mass Analysis

AT a meeting of the Royal Meteorological Society held on April 21 a paper was read by E. W. Hewson on the application of wet-bulb potential temperature to air-mass analysis, particularly in regard to the rainfall that is to be expected to result ultimately from the ascent of air in the warm sectors of depressions with various vertical distributions of wet-bulb potential temperature. Wet-bulb potential temperature was introduced sixteen years ago by Normand as a simple function of the temperature and humidity that will remain constant during any adiabatic or pseudo-adiabatic process, the name being derived by analogy with ordinary potential temperature—the temperature that any sample of air will take up when its pressure is brought adiabatically at a standard pressure. It was shown that the potential instability in a column of air is determined by the vertical distribution of potential wet-bulb temperature, and that a mass of damp air may become unstable merely by being lifted to a greater height above the ground, the condition for this being that the wet-bulb potential temperature shall decrease with height. Evidence in support of the ideas put forward is furnished by a table of data referring to a number of depressions with warm-sectors for which aerological soundings are available, and by a diagram in which the maximum rainfall in 12 hours is plotted in each case against the sum of all the decreases of wet-bulb potential temperature in the different layers through which this quantity showed a steady decrease with height. The two quantities were seen to be highly correlated, but the author emphasized that the diagram is not suitable for forecasting rainfall for the whole of a depression, but only for regions bordering the trajectory followed by the air during the 24 hours immediately after the aerological sounding which furnished the computed rainfall.

Radio Fading and Solar Eruptions

THE relation observed between the fading of high-frequency radio signals and solar eruptions is the subject of a News Service Bulletin by Dr. R. S. Richardson issued by the Carnegie Institution of Washington. The work is connected with the observations of Dr. J. H. Dellinger of the National Bureau of Standards that, between July 1934 and June 1936, thirty-nine fade-outs of radio transmissions have coincided so closely with observations of bright solar eruptions as to suggest the probability of a relationship between the two phenomena. Fifteen eruptions were photographed at the Mount Wilson Observatory of the Carnegie Institution and are described in the bulletin, which is illustrated by reproductions of spectroheliograms of the sun. From his earlier observations, Dr. Dellinger noted that the complete fading of the high-frequency radio signals occurred at intervals of 54 days, but this simple law does not appear to have been maintained since about July 1936. In co-operation with Dr. Dellinger, special hydrogen spectroheliograms have been taken at Mount Wilson with automatic apparatus, and these have been studied in conjunction with the radio records. In five cases, the time when the eruption was first seen agrees to a minute or less with the time at which the fade-out began. In six cases, the eruption preceded the fade-out by from two to twelve minutes; while in no case is a fade-out known definitely to have preceded an eruption. If continued observation confirms the relationship between eruptions and fade-outs, it would appear that the cause of the fading travels from the sun to the earth with the velocity of light; but further investigation is required to explain why some eruptions produce fading while others do not.

Deterioration of Paper

Technical Bulletin No. 541, November 1936, of the United States Department of Agriculture, Washington, D.C., deals with the "Deterioration of Book and Record Papers" and is written by T. O. Jarrell, J. M. Hawkins and F. P. Veitch. It appears to be the general opinion of librarians that much of the paper of books and records on their shelves, especially that made since about 1860, is not sufficiently durable. This conclusion applies especially in the case of books and papers subject to frequent handling. Thirty-eight samples of paper taken from old books, magazines and court records, ranging in age from 19 to 169 years, were examined. The results seem to indicate that paper actually absorbs from the air harmful quantities of acidic sulphur compounds with which the air is generally polluted. The absorption is greater in the portions of the leaves more fully exposed to the atmosphere, and this is one reason why the leaves of old books become more brittle near the outside edges. Seven samples of commercial bond and ledger papers, made in 1914 and 1915, were tested after storing under normal conditions for eighteen years. They were examined after five years and again after eighteen years storage. After eighteen years, the folding endurance of these papers had decreased 23–93 per cent and the bursting strength 0–18 per cent. In general, papers with the higher acidity, as indicated by the *p*H of their water extract, suffered the greatest deterioration. The results are indicative that a water extract with a *p*H of less than 5 is a major factor in the deterioration of even the best classes of paper.

Integrating Electricity Meters

THERE is now a great demand for prepayment meters for use among consumers who do not wish to pay a quarterly account. In a progress report on integrating electricity meters by Mr. G. F. Shotter, which is published in the February number of the *Journal of the Institution of Electrical Engineers*, various novel types of prepayment meters are described. One of these makes provision for arrears of payment which mount up owing to the consumer not inserting sufficient coins to cover the continuous collection of a fixed charge. The meter has a dial which when the consumer has inserted sufficient coins indicates by black figures the amount the consumer has overpaid, the word 'credit' in black appearing on the dial. When he has underpaid, 'credit' in black changes to 'arrears' in red, the figures automatically changing to their opposite sequence and appearing in red. Another possible difficulty due to his supply being cut off owing to arrears mounting up in his absence or for other reasons is overcome by a special device giving a limited supply for a short time upon the insertion of a coin. The current must be used immediately, as the mechanism allocates a larger proportion of the value of the coin inserted to the repayment of arrears. If the current is not so used, the balance of the value of the coin is transferred by the operation of a small motor to the paying off of further arrears. Manufacturers are also supplying prepayment meters which may be changed from D.C. meters to A.C. meters by merely changing the meter element. This type of meter would be useful and advantageous to undertakings which are supplying at present on D.C. but look forward later on to supplying some or all of their consumers with A.C. from the Grid.

Theory of Age-Hardening

RESEARCHES on the copper-aluminium alloys have resulted in the view being put forward that two kinds of hardening occur during their ageing, one of which relates to those changes which take place prior to precipitation, whilst the other is connected with the precipitation of the $CuAl_2$ itself. It has also been suggested that a concentration of copper atoms occurs at certain definite positions in the aluminium lattice prior to a copper-rich phase being thrown out of solution. It is not easy, however, to explain all the facts on the basis of existing theories, and Dr. M. L. V. Gaylor (Institute of Metals, March 1937) now proposes a modification which is believed to cover the known facts more adequately. Briefly, the new hypothesis suggests that age-hardening takes place in two stages, of which the second overlaps the first. In the initial stage, ageing is considered to be due to the diffusion of the solute atoms to the planes about which precipitation will ultimately take place. This view is in agreement with that of Desch. The next stage, which follows the first directly and takes place nearly simultaneously with it, results in some of the atoms forming molecules with neighbouring atoms of the solvent metal. As these molecular groups increase in size, local stress is set up. When the solid solution can no longer withstand these stresses their release is effected by the rejection of the compound from solid solution, and precipitation proper has taken place. It is believed that precipitation of molecular groupings intermediate between that of the solute and the solvent metal may conceivably take place and in support of this view intermediate structures between that of $CuAl_2$ and the aluminium or solid solution have been observed. It follows that age hardening is now considered as being due not so much to the precipitation itself but rather to th mechanism by which the alloy passes through the metastable to the stable state.

Monaco Conference on Corrosion

A VERY successful conference on corrosion was held at Monaco on March 25–27 under the direction of the Académie Méditérranéenne. It was attended by most of the French authorities on corrosion and by a number of delegates from other countries; the latter included Sir Robert Hadfield and Prof. S. M. Dixon, representing the Institution of Civil Engineers, Dr. J. C. Hudson, representing the Corrosion Committee of the Iron and Steel Institute, Prof. J. Timmermans, of Brussels, and Prof. T. O. Rotini, of Milan. Although, apart from one or two original contributions, most of the papers presented dealt with investigations already undertaken or completed by the various authors, they may be taken as representing the general trend of thought as regards corrosion problems in French circles. It may, therefore, be of interest to communicate some of their most interesting features.

The inaugural session was opened by a communication from General C. Grard, who is the chairman of the Corrosion Committee of the French Air Ministry. This Committee is primarily concerned with the corrosion of such metals and alloys as are, or may be, used in aircraft. Thus, for some time after its formation in 1926, its work was confined to a study of the corrosion of light alloys, but its field of research was extended in 1929 to include such ferrous metals as are of interest in aircraft construction. This Committee has a central organization of its own[1] and is also responsible for sponsoring research work in the laboratories of French universities, for example, at Lille, where Prof. Chaudron and his pupils have been conducting fundamental and practical work of great importance for a number of years. In addition, researches are undertaken in industrial laboratories, but it would appear, from conversation with several French workers in this field, that industrial collaboration in this respect is not yet quite so advanced as in Great Britain, where as a result of the influence of the Department of Scientific and Industrial Research and the formation of research associations, there is a very real and effective co-operation between individual firms in many industries.

The necessity for much closer co-operation in industrial research is generally recognized in France, and was alluded to on at least two occasions in the course of the conference. For example, *M.* Michel, of Messrs. Jacob Holtzer, raised the question at the conclusion of his communication on the properties of certain stainless steels, and his appeal for closer collaboration in research on corrosion work was warmly received by the other delegates. It may be added that organized researches on corrosion in France are also being fostered by the Office Technique pour l'Utilisation de l'Acier, although little information about this work has yet been published.

General Grard was followed by Sir Robert Hadfield, who commenced by paying a warm tribute to the memory of his old friend, Prof. Henry le Chatelier. Sir Robert then referred to the researches on corrosion fostered by the Institution of Civil Engineers, in which he has been actively interested since their inception in 1916, and to his investigations of wrought iron samples taken from the Delhi pillar. British field tests on corrosion were also described by Dr. J. C. Hudson, who dealt more particularly with atmospheric corrosion and the work of the Iron and Steel Institute Corrosion Committee.

The biological and particularly the bacteriological aspects of corrosion were prominent features of the conference. This subject was discussed during the opening session in a paper presented by *M.* R. Legendre, the director of the Laboratoire Maritime du College de France at Concarneau, who has been interested in corrosion research for some fifteen years[2] and in particular has been responsible for numerous field tests on marine corrosion conducted at Concarneau. In the course of some experiments on painted steel specimens exposed to complete immersion in a tidal basin at this port, a peculiar type of corrosion was observed underneath the paint. Local deposits of black mud were found between the paint and the steel, below which the steel was brilliantly etched, as if by acid. Samples of this mud were subjected to a bacteriological examination in the Pasteur Institute by *M.* Veillon, who was able to isolate from it a number of distinct types of aerobic and anaerobic bacteria. Laboratory experiments, in which samples of bare or of painted steel were exposed to corrosion in a suitable medium inoculated with various cultures of these bacteria, showed conclusively that the anaerobic bacteria or the anaerobic bacteria acting in symbiosis with the aerobic bacteria promoted corrosion of the steel, as compared with the behaviour of blank specimens exposed in the sterile medium; the aerobic bacteria alone had no effect. A black corrosion product was formed which had a characteristic smell similar to that of the original mud and was considered to be iron sulphide, since analysis showed that it contained both iron and sulphur[3].

References were also made to interesting researches on protective paints conducted in the laboratories of the Office National des Recherches et Inventions at Bellevue by *M.* A. Vila and his colleagues. These have resulted in the development of an accelerated weathering test for paints and of coal tar paints pigmented with flake aluminium. The accelerated test[4] is peculiar in that the French workers have been led by their experience to abandon exposure to ultra-violet light, which is so prominent a feature of most types of accelerated testing apparatus for paints, and to rely on a wide variation in the range of temperature and of the corrosive media to which the specimens are exposed. The aluminium tar paints[5], which are not unknown in Great Britain, consist essentially of a tar medium to which suitable thinners and about fifteen per cent of aluminium pigment have been added, although, according to *M.* Coret, of the Paris Gas Company, twelve per cent of pigment should suffice. *M.* Coret also stressed the fact that the choice of a suitable tar is of great importance and that the presence of compounds that are capable of being readily nitrated is injurious, whilst Dr. J. Roux claimed, probably with justice, that these paints have inhibitive properties.

Another interesting paper was presented by *M.* F. Canac, the scientific director of the Laboratoire du Centre d'études de la Marine at Toulon, who summarized and extended the results of his work on the topography of corrosion[6]. *M.* Canac has utilized an optical method to investigate the character of the attack on a corroded surface; briefly, the method consists in studying the distribution in space of the light diffused from a corroded surface, the angle of incidence being varied. He has shown by mathematical analysis that the diffusion/time curves at different angles of incidence should be characteristic for different types of attack, for example, for uniform corrosion spreading outwards at a constant rate from a regularly distributed number of centres, for intercrystalline corrosion, etc., and he has observed close approximations to the theoretical curves in actual corrosion experiments. This method and also one described by *M.* Nicolau for studying the roughness of a surface, depending on observations of the rate of escape of compressed air from a standard orifice brought into close proximity with it, should prove of value in the study of certain types of corrosion problems.

Prof. A. M. Portevin and Dr. E. Herzog communicated the results of some tests on the corrosion of a low alloy chromium-aluminium steel exposed to sea air and to immersion in sea-water at five different ports in France and Algeria[7]. It is encouraging to note that the results showed a marked superiority in the behaviour of the low alloy steel as compared with ordinary steels, not only in the atmospheric but also in the immersion tests. This observation may be of considerable practical importance, since the improvements effected so far in the corrosion resistance of steel by the addition of small amounts of alloying elements, without markedly increasing its cost, have not proved nearly so pronounced in the case of exposure to immersion in sea-water as in that of exposure to atmospheric corrosion.

Prof. G. Chaudron gave a general survey of his researches at Lille, which deal both with ferrous and with light alloys, and stressed the fact that studies of dissolution potential should include the behaviour not only of the bare metal but also of the metal covered with its oxide film. Prof. A. Travers of Nancy communicated the results of an examination of a cast iron pipe that had suffered severe graphitization whilst lying in the soil, and concluded, as is also the view of Dutch experts who have studied the problem, that bacteriological action plays an important part in this phenomenon; the reduction of calcium sulphate in the soil as a result of bacteriological action also formed the subject of a paper by Prof. R. O. Rotini, of Milan. It is also possible that an electrolytic method of polishing metals, devised by *M.* P. A. Jacquet[8] which, the author states, does not result in the formation of a Beilby layer or mechanical disturbance of the metal, may have other interesting applications besides its effect on the structure of electro-deposits, which he discussed.

It remains to add that the arrangements of the Conference were in the capable hands of *M.* J. Desthieux, the secretary of the Académie Méditerranéenne, that thirty papers were read or presented and that at the end of the Conference the proceedings were very ably summarized by *M.* Canac, who acted as *rapporteur*.

The Post Office Speaking Clock in Great Britain

UP to the beginning of the nineteenth century the time in most towns was taken from public clocks of various kinds, which occasionally varied appreciably from one another. This was a serious obstacle to the postal services, and led to the practice on mail coaches and trains of carrying chronometers to synchronize local post office clocks with a standard clock in London. Shortly after the introduction of the electric telegraph, electro-mechanical devices of various kinds were controlled by telegraphed signals. But it was not until 1874, a few years after the Government acquired the telegraph system, that successful distribution of the 10.00 a.m. Greenwich time signal was accomplished over sixty different lines. The development of this service into the very accurate International Time Signal transmitted from Rugby radio station at 10.00 and 18.00 G.M.T. daily was made in 1927. This service has the disadvantage of not always being available in the home. The well known six 'pips' of the B.B.C. have the disadvantage of being only available at certain times. Then came the synchronous motor-clocks running on frequency-controlled mains, but at present these clocks are far from being in universal use.

The success of 'speaking clocks' abroad, especially in Paris, encouraged the General Post Office to design a speaking clock service which would be of use to every house or shop connected with the P.O. telephones. It was decided that the inaccuracy of the clock should not exceed a tenth of a second, fast or slow, and that the time should be announced six times a minute, each announcement being followed by three audio-frequency pips, the last of which gives the exact time spoken. To hear the time a subscriber connected to an automatic exchange dials the code TIM, and one connected to a manual exchange asks for 'Time'.

A technical paper on this novel service was read to the Institution of Electrical Engineers on December 3 by Dr. E. A. Speight and O. W. Gill. They pointed out that when the exchange is called at, say, 10.25, a voice is heard saying, "At the third stroke it will be ten twenty-five and ten seconds". The third of the three pip sounds gives this time precisely. The next announcement will be ". . . . ten twenty-five and twenty seconds", and so on. Most recording systems may be classified as mechanical, magnetic or photographic in principle. The gramophone is typical of the instruments which give a mechanical record. It is compact and cheap to produce, but it has a fairly high noise level which increases steadily with the fairly rapid wear occurring in reproduction. Experiments on gramophone records made in India showed that it was necessary to replace them in one or two days time. Magnetic sound recording is done by means of a steel tape, but owing to its high velocity a considerable length of tape is required. In this case the initial quality of the reproduced sound is good, but it deteriorates rapidly. The system used by the Post Office is the photographic system, and photocells are used. The technique is complicated, but the record is not subjected to any mechanical wear and is therefore, for all practical purposes, permanent.

During the first week of the public operation of the service, nearly 400,000 calls were made, and during each subsequent week the number has remained practically constant at about 200,000. The relay sets at present permanently installed can each supply 100 simultaneous calls.

Noise on the Road

THE Departmental Committee on "Noise in the Operation of Mechanically Propelled Vehicles" has published its third interim report (H.M. Stationery Office, 1*s*. net). The Committee, of which Dr. G. W. C. Kaye is chairman, was set up by the Minister of Transport in 1934. The present report is based on loudness tests carried out for the Committee by the National Physical Laboratory on some 600 'used' motor-vehicles representative of all the main types on the roads to-day, and of various ages up to thirteen years. A comparison of the results with those from the earlier tests on new vehicles, shows that on the average the used vehicles were the louder by some 4–5 phons. In the range of noise met with on the road (about 70–105 phons) ordinary motor-cars were much the quietest vehicles, while amongst the loudest were certain motor-cycles and sports cars, particularly at high speeds.

The noise from the engines of ordinary cars and commercial vehicles is louder than the exhaust noise, but with motor-cycles and sports cars the position is reversed. This fact lends support to the Committee's earlier criticism of the unsatisfactory nature of the silencing of many motor-cycles and sports cars, and the investigation generally indicates that greater progress has been made in the silencing of sports cars than of motor-cycles.

In its previous reports the Committee made the recommendation that new motor-vehicles should not be offered for sale if the loudness under prescribed conditions of test exceeded 90 phons, adding that motor-cycles should be allowed a latitude of 5 phons for two years. The Committee now proposes for vehicles actually in use on the road a limit of 95 phons (that is, about the noise in a tube train). No vehicles would be allowed on the highway if the loudness, when measured at a point 18 ft. laterally from the middle of the vehicle or 25 ft. behind the open end of the exhaust pipe, exceeded this limit in a normal running test and in a racing engine test conducted in the same way as for newly manufactured vehicles. The Committee also recommends that this limitation of loudness should be applied at first only to vehicles first registered after an appointed day, but that two years thereafter it should apply to vehicles of any age.

It will be appreciated that the noise limit proposed, while making very modest demands on the majority of manufacturers and owners of motor-vehicles, would, by ruling out the arch offenders, form a substantial contribution to the amenities of the road. It is to be hoped, moreover, in the public interest that future developments will enable the limit to be lowered as time goes on. At the Minister's request, the Committee is now investigating the noise caused by motor horns with the view of advising him whether action might usefully be taken to abolish the more strident noises of this kind. The question of the noise arising from trams and trolley buses is under examination by the Ministry in conjunction with the associations concerned.

Hirosima Wave Geometry and Field Theory

REFERENCE has already been made in this journal (Dec. 21, 1935) to the vigorous school of mathematical physics now flourishing in the Hirosima University, Japan. These investigations are continuing (*J. Sci. Hirosima Univ.*, A, 7; 1937), bringing the number of memoirs on the subject up to fifteen. A good summary of the whole series is contained in the paper "Geometrization of the Law of Physics" (*ibid.*, p. 81) by Y. Mimura.

It is claimed that the new theory bears a relation to Einstein's theory similar to that which Einstein's bears to Newton's, or to that which modern quantum mechanics bears to the old quantum theory. Einstein's theory is described as semi-geometrical, and the same term is applied to all existing unified field theories, as they are all built by a mixture of two procedures, namely, the finding of an appropriate geometry, and the finding of an appropriate invariant density to be used with a generalized Hamilton's principle, which is assumed to be the fundamental law of physics.

The Hirosima school considers that the generalized Hamilton's principle should be dispensed with, and they replace it by the condition of the complete integrability of the fundamental differential equation, which is obtained by purely geometrical means. In the hope that 'wave geometry' is identical with physics, extensive investigations of possible varieties have been carried out, including those corresponding to four-dimensional ordinary metrical geometry, to projective geometry, and to conformal geometry.

It is acknowledged that the question as to which wave geometry is to be identified with physics can only be judged by its results. The new field theory has already succeeded in deducing some important physical results, such as a gravitional wave in Maxwellian form, a line element of de Sitter's form, and one equivalent to Schwarzschild's. Perhaps it is not unfair to say that, in these days of competing unified field theories, the ordinary physicist must be allowed to suspend judgment until the physical consequences of the theories have been worked out very much more fully than has been done at present.

Astronomical Determination of Longitudes and Azimuths

HISTORICALLY the relations between geodesy and astronomy have always been of the most intimate character, and the contributions of Bessel, Struve and Gill, famous as astronomers, to measured arcs and the adjustment of observations still play a fundamental part in the determination of the figure of the earth. It was therefore appropriate, the more so since astronomy is becoming increasingly concerned in its objects and methods with physics, that the Royal Astronomical Society should have recalled its association with geodesy by inviting Prof. N. E. Norlund, president at the recent London meeting of the International Council of Scientific Unions, to deliver the annual George Darwin Lecture before the Royal Astronomical Society on May 14.

Prof. Nórlund took as his subject the astronomical determination of longitudes and azimuths. He derived a general expression for the error in a longitude determination as a function of the zenith distances of the two groups of stars observed with the transit, and showed that a corresponding expression held for the azimuth determination provided the polar distances of the groups were substituted for the zenith distances. Graphical representation of this expression showed that for the maximum attainable accuracy a considerable freedom in the choice of stars was permissible, and Prof. Nórlund showed how this freedom might be utilized to minimize the unavoidable systematic errors due to level, the positions of the stars and personal equation. This discussion in its turn naturally led to a discussion of the separation of the 'Laplace points', where the geodetic triangulation is adjusted by such astronomical observations.

Prof. Norland concluded that with stars chosen in accordance with the foregoing considerations and with the methods of observation used in Denmark, a separation of as much as 250 km. was allowable. This separation is determined by the necessity of keeping the labour of observation and adjustment to a minimum and if the occasion had permitted, many fellows of the Society would have been interested in hearing Prof. Norlund's reactions to the alternative procedure of occupying more 'Laplace points' with the simpler observational procedure made possible by the prismatic astrolabe, or an astrolable attachment to a theodolite.

The lecture was characterized by a number of asides on the technique of observation, and some of the results thereof. None excited greater interest than the concluding remarks on the longitude of western Greenland. An important piece of evidence for Wegener's hypothesis of continental drift has been the fact that longitude determinations in Greenland between 1823 and 1870, and between 1870 and 1907 showed evidence of a westerly movement of the area amounting to 9 metres per annum in the first period and 32 metres per annum in the second. Under Prof. Nörlund's direction, the Danish Geodetic Survey has occupied stations in western Greenland at two epochs separated by seven years, and in that period there has been no change of longitude. There can therefore be little doubt that Wegener's suspected movement is simply the result of errors in the early determinations of longitude.

Nitrogen Transformations in the Soil

IN his presidential address to the National Academy of Sciences, India, on January 15, Prof. N. R. Dhar gave a very comprehensive account of his work on nitrogen transformations in the soil, various aspects of which have recently been described in NATURE (137, 462, 629, 1000; 138, 648, 1060; 1936). Further evidence was provided of increases both in soil nitrogen content and in crop yield following the application of molasses, and striking results were reported in the reclamation of alkali land by molasses on the practical scale. Other carbohydrate-rich materials, and the sodium salts of fatty acids, were also shown to promote nitrogen fixation. Cow dung had a double action, not only supplying extra nitrogen but also leading to nitrogen fixation as well. With more highly nitrogenous materials, however, such as oil cake or sulphate of ammonia, a loss of nitrogen from the soil took place, especially if it was exposed to sunlight. This loss was reduced when leaves or cow-dung were also added, while molasses converted the loss into a gain, nitrogen fixation occurring in spite of the presence of much available nitrogen.

Many experiments were described on the influence of sunlight on ammonification, nitrification, nitrogen fixation and the loss of nitrogen from soils. Prof. Dhar has shown both in the laboratory and in the field that exposure to sunlight accelerates these processes, but it is necessary to point out that the heating effect of the long wave-lengths was present as well as the possibly photochemical effect of the short wave-lengths. Soils exposed to full sunlight were compared with soils that were either shaded or kept in a dark room. The higher temperature of the exposed soils would be expected to cause, on the average, greater microbiological activity, and although the author observed that the temperatures were often above the optima for bacteria in pure culture, it is unsafe to argue from this to mixed soil flora which were subject to the fluctuations between day and night temperature.

This point is raised because, while Prof. Dhar's results are undoubtedly of great interest, the *a priori* objection to the occurrence of an important amount of photochemical activity in soils in the field, based on their opacity to light, is such a real one that experiments on the subject require especially stringent examination.

Science News a Century Ago

Warwickshire Natural History and Archæological Society

THE first anniversary meeting of the above Society was held on May 23, 1837, when the Council's report was read. Though some interesting addresses had been delivered, the Council regretted not having been favoured with communications so much desired by them and so easily furnished by observant naturalists, relating to the different branches of natural history. The collections in geology and mineralogy had been greater than had been anticipated. Most of the objects had come from the cabinets of members. The sole purchase was that of a series of mountain rocks from the British Isles collected by the late Dr. Rowley, late master of University College, Oxford. The zoological collection was daily increasing. It contained about 300 birds. The curators were extremely anxious to complete and classify the collection of British birds and quadrupeds. (*Analyst*, 7, 92).

Carl Ernst Adolf von Hoff (1771–1837)

ON May 24, the eminent German geologist, Carl Ernst Adolf von Hoff, died at the age of sixty-five years. Born on November 1, 1771, von Hoff was educated at Jena and Göttingen, and at twenty years of age became a secretary in the diplomatic service of the Government of Gotha, and during the Napoleonic era held various posts. In spite of the unrest of the times, he pursued the study of geology with great zest, in 1801 founded a geological journal and became acquainted with Werner, Goethe and Humboldt. In 1818, the Royal Society of Sciences in Gottingen, acting on a suggestion of the physiologist Blummbach, offered a prize for the best "investigation of the changes that have taken place in the earth's surface conformation since historic times, and the application which can be made of such knowledge in investigating earth revolutions beyond the domain of history". This led to the writing by von Hoff of his "History of the Changes in the Surface of the Earth", published during 1822–41, which placed him in the front rank as an original thinker. Carl von Zittel, speaking of this work, said : "The fact that von Hoff's meritorious work was not properly valued, and was put in the shade by Lyell's epoch making book, which appeared almost simultaneously, is easily explained by the circumstance that the modest German man of science derived his material mainly from books, that his position did not allow him to examine in the field the questions which he discussed, and that he enriched science by no new facts ; he faced the problem as an historian, and not as an observer" (see NATURE, 72, 123, June 8, 1905).

The Royal Society

AT a meeting of the Royal Society on May 25, 1837, the concluding portion of Sir David Brewster's paper on the "Absorption of Light" was read, after which Thomas Andrew Knight (1759–1838) read a paper "On the Hereditary Instinctive Propensities of Animals", in which he referred to his observations on terriers, spaniels and retrievers ; and Captain Beaufort communicated a paper entitled "On Meteorological Deductions from Observations made at the Observatory at Port Louis in the Mauritius, during the years 1833–34–35 by John Augustus Lloyd, Esq., Surveyor-General of that Island, F.R.S." The observations, from which the results recorded in the paper were made, were nearly 50,000 in number, and were taken four times each day at the hours of 8 a.m., noon, 4 p.m. and 8 p.m. The observations were those of the barometer, hygrometer, rain gauge and the appearance of the atmosphere.

End of the Euphrates Expedition

ACCORDING to the *Annual Register* for 1837, "On May 28 the *Pembroke*, 74, arrived at Plymouth with the surviving officers and men of the Euphrates expedition. There appears no doubt, notwithstanding the disasters which have attended this preparatory expedition, that with steamers adapted for the purpose and when the navigation of the river is a little better known, that the passage from Bussorah to Beles may be made in twenty days ; and when the river becomes known in fifteen days. Beles is about 100 miles from the Bay of Antioch over which distance the mail bags might be rapidly conveyed to a steamer. The passage from Bussorah to Bombay would take a good steamer 10 days. When the whole scheme was brought into existence, communication between Bombay and England might be fairly calculated at not exceeding fifty days."

John Ericsson's Screw Propeller

ON May 28, 1837, the packet sailing ship *Toronto* of 630 tons burthen and drawing 14 ft. 6 in. of water was towed down the River Thames by the experimental steamboat *Francis B. Ogden* fitted with Ericsson's screw propeller. The *Francis B. Ogden*, the largest boat built so far for trial with a screw propeller, was named after the United States Consul at Liverpool, and was 45 ft. long, 8 ft. beam and drew 2 ft. 3 in. It was fitted with an engine having two cylinders 14 in. diameter, 12 in. stroke working with steam at 50 lb. per sq. in. She had been built at Wapping. "The new propelling apparatus", said the *Mechanics' Magazine*, "consists of two short cylinders made of wrought iron, and supported by arms of a peculiar form, which are placed entirely under water at the stern ; and made to revolve in contrary directions about a common axis. To the outer periphery of each cylinder, there is attached a series of spiral planes or plates, which may, we understand, be placed at any desired angle, according to the effect sought to be obtained, whether it be great speed or great propelling power."

Fires in London

ACCORDING to *The Gentleman's Magazine* of May 1837, of 564 fires which occurred in and around London in the previous year, the following were the causes so far as could be ascertained. Accidents of various kinds, scarcely avoidable, 11 ; apparel taking fire on the person, 2 ; bed curtains set on fire by accident, 71 ; accidents with candles, 57 ; cases of palpable carelessness, 18 ; charcoal fires, portable, 2 ; children playing with fire, 6 ; fires kindled on hearths, 5 ; defective or foul flues and chimneys, 72 ; fumigation, 9 ; sundry gas accidents, for the most part occurring from gas-fitters, during the progress of repairs, 38 ; gunpowder, 1 ; heating of hay, lime, etc., 7 ; sparks from lamps, 2 ; linen incautiously hung before fires, 31 ; ovens overheated, 6 ; loose shavings ignited, 13 ; sparks from fire, 7 ; defective setting of stoves, etc, 28 ; application of fire heat to various purposes of trades and manufactures, 34 ; tobacco smoking, 1 ; unknown, 95 ; wilful, 8 ; window curtains catching fire, 35.

University Events

CAMBRIDGE.—The Gordon Wigan Prize in Chemistry for 1936 is divided equally between A. E. Alexander, of King's College, and T. P. Hughes, of Gonville and Caius College.

LONDON.—Prof. A. M. Carr-Saunders, Charles Booth professor of social science in the University of Liverpool, has been appointed director of the London School of Economics and Political Science as from October 1, in succession to Sir William Beveridge.

OXFORD.—E. J. Bowen, University College, and J. W. Wolfenden, Exeter College, have been appointed University demonstrators in chemistry for four years as from October 1. Dr. B. G. Maegraith, Exeter College, has been appointed University demonstrator in pathology for four years from May 1.

M. A. Jennings, Lady Margaret Hall, has been elected to the Schorstein research fellowship in medicine for 1937.

H. Field, New College, has been granted the degree of D.Sc. for his work in anthropology. Prof. J. C. Moir, Oriel College, has been given the degree of M.A. by decree.

The amount subscribed in the first three months to the University appeal for approximately a million pounds is £355,845.

Societies and Academies

Paris

Academy of Sciences, April 12 (*C.R.*, 204, 1093–1144).

LUCIEN CAYEUX: Signification of the disturbances recorded by the phosphates of Hodna (Algeria) during and after their deposit.

CHARLES MAURAIN: Possible influence of mechanical actions (vibrations) and magnetic disturbances on the earth's magnetic field, and its anomalies.

EMILE MATHIAS: Curvature of the diameter of densities.

JULIUS WOLFF: Invariant domains in conformal representation.

JOSEF L. KRAMES: A remarkable class of space movements. Symmetrical viration.

RENÉ DUGAS: Dirac's mechanics and the last multiplier in the sense of Jacobi.

ARCADIUS PIEKARA: The phenomenon of positive electrical saturation.

JULES FARINEAU: Spectrographic study of the conductivity electrons of magnesium and silicon.

MAURICE PARODI: Study of some borates and some oxides in the extreme infra-red

JULES DUCHESNE: Calculation of the vibration frequencies of the molecule N_2O_4.

ANDRÉ GUINIER: An arrangement for obtaining very intense diffraction diagrams of crystalline powders with a monochromatic radiation.

ANDRÉ MERCIER: The theory of β-radioactivity.

JULES GUÉRON: The general trend of the evolution of aqueous solutions of ferric chloride.

MLLE. MARGUERITE FROLLO: The petrographical study of the radiolarian complex of the Mesozoic formations of the Eastern Carpathians.

GABRIEL LUCAS: The Palæozoic of the Ghar Rouban region (Algero-Moroccan frontier).

EUGÈNE WEGMAN: Genesis of the alkaline rocks of Julianehaab (Greenland).

WILLIAM HENRI SCHOPFER: The nitrogen metabolism of a micro-organism, considered from the point of view of allometry.

ROBERT ECHEVIN: The influence of calcium carbonate on the growth of the radish.

MLLE. MARIE THÉRÈSE GERTRUDE: The determinism of the morphogenic action exercised by the aquatic medium in plants.

HENRI GAUSSEN: The evolutionary equilibrium and the germinal influence in the Abietineae.

ANDRÉ TOURNADE and MARC CHEVILLOT: Concerning the Philippeaux-Vulpian experiment.

MAX LAFON: The biometrical study of cystine deficiency in the rat.

R. HERPIN: The periods of fixation of the animal organisms determining the fouling of ships' hulls.

Rome

Royal National Academy of the Lincei (*Atti*, 24, 99–171; 1936).

E. SOLER: Geophysical work carried out by the Institute of Geodesy of the Royal University of Padua in the Vesuvian region in 1934–35.

A. RUSSO: Chondriome increment and activation of metabolism.

C. PAUC: Curvature in metrical spaces.

C. MINELLI: Continuous bent beam stressed axially, with a bending rigidity which is variable linearly along each span.

E. GUGINO: Trajectories of variational problems.

G. BERNARDINI and D. BOCCIARELLI: Energy and intensity of groups of neutrons emitted by Po + Be (2).

G. TEDESCHI: Causes of the evolution of oxygen from lead accumulators at rest.

L. MONTI: Oxidizing action of selenium dioxide (2).

G. CENTOLA: Researches on the process of stabilization of nitrocellulose.

R. SAVELLI: Some manifestations of the reducing power of vegetable tissues (1). Development and adaptation of some plastids (2).

G. CASALAINA: An eleochloroplast with a positive Ciaccio secretion.

A. AGOSTINI: Statistical studies on the variability of the goatsucker (*Caprimulgus e. europæus* L).

T. PERRI: Correlative processes of determination and of growth of the lens-forming rudiment in Amphibia (3). Experiments on *Bufo viridis*, *Bufo vulgaris*, *Rana agilis*, and *Rana esculenta*.

(*Atti*, 24, 175–238; 1936).

U. CISOTTI: Behaviour at the boundary of well-known analytical integrals.

L. TONELLI: Equations in the problems of Mayer.

U. MORIN: Ensemble of linear spaces contained in an algebraic hypersurface (1). Unirationality of the algebraic hypersurfaces of the fourth order (2).

B. SEGRE: Topological invariants relative to the united points of the regular transformations between superposed varieties (1). A complement to the correspondence principle, for correspondences with zero valence on the algebraic curves (2).

R. L. GOMES: A correction of the note on the operator *S*—Schrodinger's operator.

G. B. BONINO and R. MANZONI-ANSIDEI: Raman spectrum of thiophene.

G. PICCARDI: Presence of molecular hydrogen in sunspots (1).

G. SCAGLIARINI and G. AVONI: Colour reaction between nitroprusside and glutathione.

M. FENOGLIO: Natural neutral and basic hydrated carbonates of magnesium.

C. LENTI: Osmotic pressure of the colloids of vitreous humour.

L. SANZO: Rearing of a pelagic larva of *Cerianthus* up to the stage of acquiring definite characteristics.

C. KOCH, B. SCHREIBER and G. SCHREIBER: Attempts to graft tissues in the vitreous humour of the guineapig's eye.

S. MINZ and E. SERIANNI: The action of adrenaline and of atropine on experimental alcoholæmia.

(*Atti*, 24, 239–313; 1936).

L. TONELLI: Equations in the problems of Lagrange.

G. A. MAGGI: Notable complement of Love's conditions (at the wave-front of a succession of electro-magnetic waves) and its applications.

B. SEGRE: A complement to the correspondence principle, for valency correspondences with united points of any multiplicity (2).

R. CACCIOPPOLI: Inverted functional correspondences: general theory and applications to some nonlinear functional equations and to Plateau's problem.

G. ARRIGHI: Dynamics of the deformable body with variable mass (1). Motion of a compressible fluid of variable mass with forces derived from a potential (2).

L. CESARI and F. CONFORTO: The equation of the three moments for a continuous bent beam stressed axially, with a bending rigidity which is variable linearly along each span.

M. MAGGINI: Attempts at photo-electric photometry of planetary surfaces.

E. SEGRÈ: Selector of velocity of slow neutrons.

G. PICCARDI: Presence of molecular hydrogen in sunspots (2).

G. B. BONINO: Molecular symmetry of thiophene (1).

G. SCAGLIARINI: Action of nitroprusside on pyrroles.

G. REVERBERI: 'Total' segmentation in the fragments of the fertilized egg of Ascidians.

C. JUCCI: Rearing of *Reticulitermes lucifugus* in sample tubes.

A. CAPPELLETTO: Development of the embryo in rarified air (1). Growth of tadpoles.

C. LENTI: Modifications of basal exchange in high mountainous regions.

Washington, D.C.

National Academy of Sciences, *Proc.*, 23, 133–187, March 15.

D. F. POULSON: Chromosomal deficiencies and the embryonic development of *Drosophila melanogaster*. By observation of living eggs, and by means of sectioned material, it is concluded that sections of the X-chromosome are essential for certain specific processes in embryonic development. The larger the section missing, the earlier and more general are the effects.

C. W. METZ: Deficiencies and structural variations within the giant chromosomes in relation to the problem of gene structure. A review of recent investigations.

K. V. THIMANN and G. W. BEADLE: Development of eye colours in *Drosophila*: extraction of the diffusible substances concerned. Water extracts of wild-type larvæ, made in a nitrogen atmosphere, contain substances which, when injected into test larvæ, are capable of changing vermilion and cinnabar eye colour towards wild type. The substances are probably neither protein nor enzyme in nature.

G. W. BEADLE: Development of eye colours in *Drosophila*: fat bodies and Malpighian tubes as sources of diffusible substances. Extract of fat bodies is capable of affecting the eye colour of genetically vermilion flies; extract of Malpighian tubes has a similar effect on genetically cinnabar flies.

B. R. COONFIELD: The regeneration of plate rows in *Mnemiopsis leidyi* Agassiz. There are eight such rows in the body of this ctenophore, and rapid regeneration following natural or experimental injury takes place in the sequence healing, stretching of remaining parts of canal and concentration of mesogleal cells in the wound area, fusion of parts of canal and formation of plates above the new canal.

E. U. CONDON: Immersion of the Fourier transform in a continuous group of functional transformations.

H. WALLMAN: Lattices and bicompact spaces.

J. L. WALSH: Curvature of orthogonal trajectories of level curves of Green's function.

W. A. SETCHELL and N. L. GARDNER: *Iridophycus* in the northern hemisphere. Brief descriptions and a key are given.

H. C. YIN: Effect of auxin on *Chlorella vulgaris*. Measurement of individual cells after experiments lasting 2, 3 or 10 weeks showed that pure heteroauxin (β-indole-acetic acid) promotes cell enlargement in this alga as it does in higher plants. No conclusive effect on total growth was observed in cultures containing 0·001–0·01 mgm./c.c. of heteroauxin, and higher concentrations had injurious effects.

F. L. WHIPPLE and J. L. GREENSTEIN: Origin of interstellar radio disturbances. Jansky has observed continuous electromagnetic disturbances of wavelength 14·6 metres which appear to come from an extra-terrestrial source approximately coinciding with the galactic centre in Sagittarius. A theoretical investigation indicates that this radiation is unlikely to be caused by thermal agitation of charged particles in interstellar space.

I. ROUSE: New evidence pertaining to Puerto Rican prehistory. Three expeditions from the Peabody Museum have investigated Puerto Rica, the last in the summer of 1936. Evidence has been obtained of an early period when no pottery was used. The succeeding pottery period can be divided into three periods, Crab (painted), Intermediate (undecorated) and Shell (incised). A single people probably inhabited the region, gradually changing their pottery and food habits under the influence of neighbouring peoples.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, May 24

Royal Society of Arts, at 5.15.—Sir Gwilym Gibbon: "The Public Social Services".

University College, London, at 5.30.—Dr. D. McKie: "Development of Theories regarding Combustion and Respiration in the 18th Century".*

Imperial College of Science and Technology, at 5.30.—Prof. I. M. Heilbron, F.R.S.: "The Chemistry of the Carotenoids and Vitamin A" (succeeding lectures on May 25 and 26).*

Royal Geographical Society, at 8.30.—L. Wager. "The Kangerdlugssuak Region of East Greenland".

Tuesday, May 25

Eugenics Society, at 5.15—(at the Royal Society, Burlington House, Piccadilly, W.1).—Dr. R. R. Kuczynski: "Future Trends in Population".*

University College, London, at 5.30.—Dr. F. G. Young: "The Development of certain Aspects of Metabolism during the 19th Century".*

Wednesday, May 26

Warburg Institute, at 5.30.—Dr. R. Klibansky: "Religion and Science in the Twelfth Century".*

Birkbeck College, London, at 6.—Sir Arthur Eddington, F.R.S.: "The Reign of Relativity 1915–1937" (Haldane Memorial Lecture).*

Royal Society of Arts, at 8.15.—Prof. H. D. Kay: "The Biochemistry of Milk Secretion".

Thursday, May 27

Royal Asiatic Society, at 4.30.—Sir Arnold Wilson: Burton Memorial Lecture.

University of Oxford, at 5 (in the Examination Schools).—Dr. Joseph Needham: "Integrative Levels, a Revaluation of the Idea of Progress" (Herbert Spencer Lecture).

Royal Aeronautical Society, at 6.30.—Dr. Theodor von Kármán: "Turbulence" (Wilbur Wright Lecture).

Friday, May 28

University of Oxford, at 5—(in the University Museum).—Dr. B. F. J. Schonland: "The Lightning Discharge" (Halley Lecture).

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant in H.M. Nautical Almanac Office—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (quote C.E. 3157/37) (May 29)

Principal of the Cardiff Technical College—The Director of Education, City Hall, Cardiff (May 29).

Principal of the Croydon Polytechnic and Evening Institutes—The Education Officer, Education Office, Katharine Street, Croydon (May 29).

Lecturer in Botany, University Demonstrator in Botany and University Demonstrator in Plant Physiology in the University of Cambridge—Dr. A. D. Imms, Department of Zoology, Downing Street, Cambridge (May 31).

Lecturer in Mechanical Engineering in the Technical Institute, Gainsborough, Lincs.—The Principal (May 31).

Assistant Lecturer in Mathematics in King's College, London—The Secretary (June 1).

Assistant Lecturer in Physics in the University of Manchester—The Registrar (June 12).

Lecturer in Botany in the University of Reading—The Registrar.

The Special Areas and the Location of Industry

Industrial Survey of South Wales

THE necessity for close attention to the location of industry has in recent months received repeated emphasis, and nowhere more than in the three volumes* comprising the Second Industrial Survey of South Wales, undertaken for the National Industrial Development Council of Wales and Monmouthshire by Prof. H. A. Marquand and a staff of assistants with the aid of a grant from the Commissioner for Special Areas. The First Industrial Survey of South Wales was made for the Board of Trade by University College, Cardiff, in 1931, and was designed merely to determine the surplus of labour attached to the existing industries of South Wales. Nevertheless, valuable work was done, and the significant reference in the present report to the difficulties which were experienced, simply because the limited resources of the College made it impossible to keep continuously up to date the information which had been prepared and collected in the Survey, will not be overlooked by those who appreciate the value and significance of such research.

The subsequent report of Lord Portal in 1934 was in no sense a survey but rather a collection of recommendations as to Government policy, and its information on industry and employment was restricted to the eastern section of the coalfield. The present survey, on the other hand, was designed to supply an answer to three specific practical questions:

(1) What is the present state of employment in the various industries in South Wales, and the probable future of employment in those industries?

(2) What facilities can the region offer to new industries which may be established within it?

(3) What new industries can most profitably be introduced into the region and where can they best be located?

To each of these questions a volume is devoted, and if the thoroughness with which the Survey has been conducted has inevitably meant a bulky report, the report is none the less a model of the type of guidance required by Government and industry in the day-to-day and detailed task of reconstruction. It is authoritative, balanced, practical and constructive, and outside the region itself, the main findings of the Survey merit the careful consideration of administrators and business men who may be affected. A wide range of concrete problems is examined with detachment and common sense, and the consistent regard for sound economic principles, combined with the impressive grasp of industrial problems and technique which it displays, give it claims on the attention of all who are interested in Great Britain's industrial future. For the general reader, an admirable summary and survey of the report has been issued by Political and Economic Planning (PEP); but the scientific worker will at least turn to the first and third volumes of the full report, if the interest of the second volume with its detailed survey of facilities is mainly for industrialists considering possible locations for factories.

The first volume of the report, which discusses the size and distribution of the population of South Wales and attempts to forecast its probable future development, in itself powerfully supports Sir Josiah Stamp's latest plea for the study of population questions. The Survey shows that while there has been some recovery from the depths of the depression of 1930–33, a mass of chronic unemployment remains which is peculiar to this and other depressed areas which have not developed large new industries to compensate for the contraction of basic activities such as coal mining and steel making.

---

* The Second Industrial Survey of South Wales. (Published on behalf of the National Industrial Development Council of Wales and Monmouthshire.) Vol. 1: Industries. Pp. 500. 15*s*. net. Vol. 2: Facilities. Pp. 295. 10*s*. 6*d*. net. Vol. 3: Development. Pp. 404. 10*s* 6*d*. net. (Cardiff: University of Wales Press Board; London. Oxford University Press, 1937.)

Coal mining is by far the most important industry in South Wales, accounting for more than a third of the insured workers, although fourteen years ago it accounted for half. While the number of miners wholly unemployed remains at about its peak level, the number temporarily unemployed has been greatly reduced. The report estimates that there is a surplus of about 80,000 workers in the area, 70,000 of whom are from the mining industry, and a considerable proportion of this surplus consists of men too old to obtain employment on commercial terms. This is one of the important factors to which special attention is directed in the report.

This surplus is attributed partly to the inevitable results of technological development and partly to the growth of economic nationalism. Recognizing that it is an essential foundation of a rising standard of living that such commodities as steel, ships or bricks should be produced by a diminishing number of workers, and also that it is desirable that new and more economical methods of satisfying essential needs should be developed if possible, the report emphasizes the importance of re-absorbing the displaced labour after an interval in new industries and services as a normal remedy. Moreover, the case for State action to stimulate the introduction of new industries is strengthened by the fact that the over-expansion of the heavy industries, although probably unavoidable, was due to the needs of the State itself.

The problem, in fact, is not merely one of dealing with the hard core of unemployment by alleviating the lot of some thousands who have been unemployed for a prolonged period, but also the much larger problem of regional development. Even if employment in the heavy industries were fully restored, areas like South Wales would remain relatively depressed because of low wages, the large number of dependants per wage earner and the scarcity of employment for female labour. Throughout the report, emphasis is laid on the dangers of piecemeal or haphazard action, and the case for deliberate consideration by the State of regional development and the planned location of industry, as opposed to the almost accidental influence exerted in the past, is admirably argued. Only as the location of industry is considered in relation to long-term advantage can we hope for a successful policy, and the need for a careful statement of the theory of location is evident even if practical action and policy cannot wait for such a statement.

The present report, however, directs attention to several factors to be considered in arriving at decisions in the meantime. Thus, it indicates that technical developments have diminished the importance of location near coalfields or proximity to raw materials, and increased the strength of the pull exerted by other forces. The tractability, rather than the cheapness, of labour is now the important factor. At the same time the influence of local rates tends to increase, even though derating has removed much of the handicap under which the depressed areas laboured in competition with the south-east and south-west of England before 1929.

The review of industries and population leads to the conclusion that further State aid in encouragement of new industries in South Wales would be economically justified. Some transfer of labour to other parts of Great Britain should continue, but the main emphasis is laid on the introduction of new industries. Some such industries merely need certain inducements to overcome unjustified prejudices against location in South Wales. Some may need the assistance which the establishment of trading estates could give. The success of all, however, depends upon the width of the market to which they can easily have access, and it is for this reason that an improvement in the transport services connecting the region with the rest of England is so desirable.

The second and third volumes of the Survey are in fact mainly devoted to the examination of questions involved in the introduction and development of new industries. The second volume, which outlines in some detail the existing facilities, is naturally chiefly of interest to the industrialist considering a definite step in that direction ; but the third volume, which examines the new industries which might be established, and discusses the improvements in facilities necessary for their success, has a much wider interest and in particular a number of claims upon the attention of scientific workers.

The detailed treatment of labour supply and demand which occupies half this third volume alone emphasizes the necessity for some rational treatment of the problem, if only to minimize the amount of waste in cross-travel and to deal with the needs of the 20,000 older men of fifty to sixty-five years of age who are unlikely to be employed again. Some extension of the social service club system might be of vital assistance in restoring a sense of function to these men, by enabling them to use their creative powers to supplement their family income. The removal of any deterrents to their migration and reunion with other members of their family in a new district is another promising and constructive line of approach to this problem of the growing preponderance of the middle and older age groups among the wholly unemployed in the Special Areas.

It is, however, in the third and fourth chapters of this volume that the scientific worker will find the material of most immediate concern to himself. In its discussion of possible new industries, the report lays special stress upon the possibilities of the plastics industry, and argues a strong case for consideration. If the manufacture of all or most types of plastics were undertaken on an economic scale in South Wales, in a few years the industry might provide as much employment in the region as it gives the whole country now. As a means of providing employment, the plastics industry is far superior to schemes for oil from coal or low-temperature carbonization, or synthetic nitrogen, though the report emphasizes the desirability of locating such plant in an area so much less vulnerable to attack than Billingham.

The soundness of the survey is indeed well illustrated by the way in which this question of the plastics industry is discussed. If the industry is introduced at all, it is highly desirable that a range of new materials as complete as possible should be made in the region, because plastic materials are competitive to some extent with each other as well as with other materials. Any one particular type of plastic material may easily be driven out of the market by a new, better and cheaper material made elsewhere.

Part of the value of the plastics industry to South Wales would lie, however, in the assistance it could give to other industries in the area by using products obtained in the area and by stimulating other industries such as the establishment of a new chemical industry, the paint industry, the electrical industry and many light industries. The question, as the report insists, needs considering in relation to a far-reaching policy of industrial location, and to discuss with the industry as a whole the possibility of giving a fair trial to such a region as South Wales is a manifest responsibility of the Government, in keeping with its recognized responsibility for securing fair play for British trades overseas.

In an admirably balanced review of possible improvements in facilities, a convincing case is urged for a Severn bridge scheme as well as for the improvement of railway services. Tourist development has hitherto been amateurish and piecemeal, and offers a distinct field, particularly in Pembrokeshire and the Gower Peninsula. A national park in the Vale of Neath is also proposed, while the threat which ugly and random development present to the amenities of South Wales once more attests the need for planned development.

The present investigation in itself accordingly underlines its own very modest and restrained recommendations in regard to research. The trading estates should provide for their tenants some form of market research and economic advisory service. A far better service should also be available than now exists to provide information and guidance on wider problems common to the whole region, at the very least on those affecting the basic industries. As a manufacturing region, South Wales suffers severely from the absence of such services as the economic research sections in the University of Pennsylvania or the University of Manchester perform for their respective regions. Subsidization of university research on these problems might yield very valuable results for very small expenditure.

No one can study this report or even the admirable summary and commentary on it issued by Political and Economic Planning without realizing the important function which dispassionate scientific inquiry can fulfil as a basis for action. The long-range planning of industry is indeed only possible in the light of the knowledge so acquired. Repeatedly in this admirable survey the necessity for considering the problems of the Special Areas in relation to the whole problem of national development or recovery appears, as does the futility of any narrow or rigid treatment of the boundaries of the areas in regard to financial or other facilities for development or planning. Scientific workers who have the patience to study these volumes for themselves cannot but be strengthened in their conviction that science has its own special contribution to make to the solution of these difficult problems.

Aspects of Palæogeography

(1) Die bionomische Einteilung der fossilen Meeresböden

Von Hermann Schmidt. (Fortschritte der Geologie und Palæontologie, herausgegeben von Prof. Dr. W. Soergel, Band 12, Heft 38.) Pp. vi+154. (Berlin: Gebrüder Borntraeger, 1935.) 16 gold marks.

(2) Geomorphologie der feuchten Tropen

Von Karl Sapper. (Geographische Schriften, herausgegeben von Alfred Hettner, Heft 7.) Pp. vi+154+4 plates. (Leipzig und Berlin: B. G Teubner, 1935.) 6 gold marks.

(3) Géologie stratigraphique

Par Prof. Maurice Gignoux. Deuxième édition entièrement refondue. Pp. vii+709. (Paris: Masson et Cie., 1936.) 95 francs.

(4) Paläogeographie und Tektonik

Von Prof. Dr. Franz Kossmat. Pp. xxiii+414+5 plates. (Berlin: Gebrüder Borntraeger, 1936.) 18.20 gold marks.

(5) Die Entwicklung der Kontinente und ihrer Lebewelt

Von Theodor Arldt. Zweite, vollständig neubearbeitete und erweiterte Auflage. Pp. 448. (Berlin: Gebrüder Borntraeger, 1936.) 28 gold marks.

THERE can be nothing duller than the detail of stratigraphical geology and, let us hasten to add, nothing more exciting than the vision of the endless succession of past geographies based upon that detail. In the great pile of sedimentary and igneous rocks that make the earth's crust, there lie records of an ever-changing distribution of lands and seas, of the growth and decay of great mountain ranges, of extreme variations in climate and of the continuous succession of life-forms. Each in its own fashion, the five volumes considered here are notable contributions to this science of palæogeography.

(1) In the first book, the advances in hydrobiology are applied to the interpretation of facies, that is, the sum of all lithological and palæontological characters of a sediment. The various lines of attack in the study of facies-differences are critically examined, and then the foundations of a bionomic classification of sea bottoms established. The oxygen content of the bottom waters is taken as the most important factor. Two chief classes of bottom conditions, sweet and stagnant, are developed and their subdivisions viewed in the light of modern oceanography. These bionomic concepts are then applied to the interpretation of the sediments of the stratigraphical column. The book concludes with a study of special facies problems, such as those of the flysch, black clays, etc., and of aspects of adaptive morphology of sea animals. Throughout are given comments upon the habitat and significance of a great number of common fossils, and the work as a whole is an important contribution to that branch of palæogeography which the author calls palæohydrobiology.

(2) Prof. Sapper's small volume, though largely concerned with the development of land forms in wet tropical regions, deals also with certain topics of great interest to the palæogeographer. Of these, one only can be mentioned here, and that is the complete confirmation of the view that coarse unweathered arkoses, so often taken as indexes of arid or semi-arid conditions, are typically developed in humid tropical areas. It may be observed, in passing, that Sapper's book should be read by all British geologists, as it supplies a much-needed corrective to the notions of many of them concerning the scale of erosional processes.

(3) The first edition of Prof. M. Gignoux's "Géologie Stratigraphique" has been a standard and invaluable text-book in Britain for a decade. This largely rewritten and expanded second edition is more than a text-book, for, by its wealth of references and inclusion of new work, often relatively inaccessible, it will be of value to the specialist as well as to the student. The chief modifications are these. The treatment of the Palæozoic has been remodelled, and includes new data on, for example, the Saar Coalfield, the Russian Carboniferous, and the Permian of Timor and China. Full accounts of North African stratigraphy and tectonics have been added. The history of Gondwanaland has been synthesized. A new treatment of Alpine stratigraphy brings out very clearly the relations between sedimentation and tectonics, and a new introductory chapter deals with these relations on more general lines.

We have in this book a charming presentation of the philosophy of stratigraphical geology. Lately, there seems to have developed a tendency for geologists to show their versatility by the inclusion of passages of music in their writings, and Prof. Gignoux ends with a few bars of Wagner.

(4) In the fourth volume to be noticed here, Prof. F. Kossmat deals with the relationships between palæogeography and the tectonic shaping of the earth's surface. He is concerned not so

much with the fluctuations of the margins of the continental masses during successive periods of earth history, that is, with palæogeography in a narrow sense, but more with the movements of the crust which gave rise to such fluctuations. Changes in the successive mountain belts of geological time are to be traced step by step.

The first part of the book gives a rather compressed summary of the geological history and facies observations for the whole world, and this is followed by a tectonic analysis of the major divisions. Two kinds of continental masses are separated, the circumarctic controlled by its folded margins, and the high plateaux of Gondwanaland. Finally, more general topics are discussed—among these being the polar asymmetry of the earth's crust, critical times in earth history, the cause of earth movements and many others. Throughout the work there are many new observations and, in part, new interpretations that will be of interest to tectonic geologists.

(5) The last volume before us forms the first part of the second edition of Prof. T. Arldt's great work dealing with the distribution of present and past life. At the beginning the question of the permanence of continents and oceans is asked, and the whole work will provide an answer to this question. After a stimulating essay on the methods of palæogeography, the author begins his heavy task by an exceedingly detailed examination of the distribution of present and Tertiary forms of life in the Australasian, South American and Madagascar regions, and this examination takes up the greater part of the volume.

Among this mass of detail there are several more general sections of interest to the palæogeographer, in which conclusions are drawn concerning connexions by land-bridges between the various regions dealt with. Arldt concludes that during the Mesozoic these regions were connected with the northern land masses. The first bridge to collapse was that between Australia and India, then that between India and Madagascar was broken, and finally that between South and North America. The equatorial connexion between the three regions dealt with lasted much longer, and junctions with the northern land masses, that had been severed in Eocene times, wére re-established in the Pliocene. It seems, therefore, that land-bridges, in spite of Wegener and still more orthodox schools, are not yet a lost cause in palæogeography.

David Gregory

David Gregory, Isaac Newton and their Circle
Extracts from David Gregory's Memoranda, 1677–1708. Edited by W. G. Hiscock. Pp. ix+48. (Oxford: W. G. Hiscock, Conway, Squitchey Lane, 1937.) 10*s*.

THIS is one of the MSS. of David Gregory, preserved at Christ Church, Oxford, accompanied by some brief notes of the editor, Mr. Hiscock, who seems to have done them very well. The interest of this publication centres around the name of Newton. It is only by making available the views of his contemporaries that we can realize Newton. To print an account is very much the most effective way of making it available. If a thing is written down, it remains, and if it is printed, many people read it. Their views, even if diverse, and even if negligently formed, congeal about something common to all. It may be compared with the short issue of Stukeley's account, recently reviewed in NATURE (138, 617; 1936).

Reading the book through, one finds many differences from modern practice. One realizes, for example, that anti-Christ was a real person to them, and that they knew nothing at all about chemistry, and had not the means to produce any high temperatures, otherwise than by burning glasses. Newton was, in fact, the first of the moderns; he understood exactly the basis our conventions rest upon. We owe to him very much more than is usually ascribed; we owe him the whole direction of modern investigation.

The present transcript consists of personal notes about all sorts of subjects, most of them dated, for the use of David Gregory. Gregory's relations with Newton are well known, and they seem to have suffered from no cloud. Newton does not directly figure in these memoirs, but there are many references to him, and some important ones —one, for example, that Mr. Hiscock considers so important that he has photographed it and produced it as a frontispiece. It serves to emphasize Newton's conception of matter; it relates to the question of matter being proportional to weight. To quote two statements that strike us, from the text: "3 March 1698/9 . . . And its as universally received in England that the winters are milder as it is that the summers are colder" and "May 1708. Algebra is the Analysis of the Bunglers in Mathematicks. Sir Isaac Newton".

R. A. S.

Contemporary American Philosophy

(1) A World of Chance:
or, Whence, Whither and Why? By Prof. E. G. Spaulding. Pp. xxxiv+293. (New York: The Macmillan Co., 1936.) 12*s*. 6*d*. net.

(2) The Logical Structure of Science
By Prof. A. Cornelius Benjamin. (Psyche Monographs, No. 9.) Pp. 344. (London: Kegan Paul and Co., Ltd., 1936.) 10*s*. 6*d*. net.

(3) Personal Realism
By James Bissett Pratt. Pp. xi+387. (New York: The Macmillan Co., 1937.) 15*s*. net.

(1) OF these three books, all by American philosophers, the first is concerned with the ultimate structure of the universe, the second with the nature of scientific thought and the third with metaphysical conclusions derived from a realistic epistemology. The first, by Prof. Spaulding of Princeton, is a further development of the new realism with which he has been identified and is, primarily, a defence of the thesis that ontological contingency is a logical necessity. Prof. Spaulding holds that there is no ultimate unity except the unity of totality, and his 'ultimates' or 'irreducibles' consist of five properties—possibility, contingency, propertiness, ultimacy and reality. Each of these is an instance of itself as well as of the other four; and, in order to obtain this finality, he deliberately violates the theory of types. Prof. Spaulding asserts that, while all existing entities are possibilities and all possibilities realities, not all possibilities are realized in Nature. He maintains that in the structure of reality, shot through with chance and indeterminism, Nature is but a chance instance which *is* but need not be, that there is no necessity for the existence of even that objective realm of possibilities one of which is realized as Nature, and, finally, that the whole of reality, including logical entities and values, is contingent.

The new development in Prof. Spaulding's philosophy consists largely in a synthesis of the results of research in symbolic logic, in the physical sciences, emergent evolution and the theories of knowledge and values. But here, quite apart from the possible complications arising from his violation of the theory of types in arriving at his ultimates, there is an epistemological chasm which, to the reviewer, he does not appear to have bridged satisfactorily even by his theory of external relations. In another instance of the theory of types, namely, the interpretation of the indeterminacy principle which asserts that nothing can be observed as it really is because observation disturbs that which is observed, Spaulding refutes the argument by declaring that this again leads to an infinite regress For, if observation disturbs that which is observed, then that in turn becomes the observed to another observation, and so on, indefinitely. Thus he arrives at knowledge by refusing to accept an infinite regress.

Whether or not there are positive advantages to be gained by this freedom for postulation, Prof. Spaulding's method is undoubtedly a very interesting contribution to contemporary philosophy.

(2) Although mistrustful of labels, Prof. Benjamin calls himself a critical positivist and bases his inquiry into the nature of science upon the firm conviction that all philosophy and science must start with the given, which is subdivided into the realms of the clearly given and the obscurely given. The task of science is to symbolize the total realm of the given by discovering the relations connecting the clearly given with the obscurely given. Thus, in his view, methods of construction and reduction are essential; but he differs from the positivists in insisting that not all constructions and derivations should be given an unreal status. Hypothetical entities are not to be denied, but are to be relegated to the realm of the obscurely given.

In Prof. Benjamin's philosophy, an occurrent takes the place of an event, an object, or any other term representing the basic subject-matter of science. An occurrent has form and content, and genuine knowledge consists in being aware of an occurrent, of a symbol for the occurrent and also of a symbol for the relation between the two. In a careful argument he shows that if one of these is lacking, there is no science in the strict sense.

There is much of interest in Prof. Benjamin's thesis including, in particular, his operational theory of meaning. It is to be hoped that his tentative solutions of these problems will inspire the criticism and discussion which he invites.

(3) Prof. J. B. Pratt is one of the seven American authors of the famous "Essays in Critical Realism" which appeared in 1920. The present book is the outcome of his further deliberations on the problems of epistemology which were the subject of the earlier work and, more particularly, on the metaphysical consequences to be drawn from them. So far as epistemology is concerned, Prof. Pratt is still a critical or—as he now prefers to term it—dualistic realist, inasmuch as he

maintains that at least three factors are necessary in the knowledge situation, namely, the conscious subject, the mental content and the object. It is in the metaphysical conclusions that he parts company with some of his erstwhile colleagues. For Prof. Pratt is of the opinion that in many cases the naturalistic consequences which were drawn were unjustified, and that the doctrine of knowledge espoused by the group led "to the conception of a partial independence and spontaneity of mind and of the reality of a substantial self"

While it is obvious that, in working out his conclusions, Prof. Pratt has studied with great care the latest developments in logical and philosophical doctrine, yet, to the reviewer at least, there is a distinct flavour of 'other days' in his writing which is reminiscent of the pre-symbolic epoch when 'metaphysics was metaphysics'. But he is consistently suggestive rather than dogmatic; and even in the final chapter where his "over-beliefs" take the form of a spiritual pantheism, he only claims for them, as for the rest of his conclusions, a "balance of probability". A. v. Z.

Musical Instruments and their Distribution

Origine des instruments de musique: introduction ethnologique à l'histoire de la musique instrumentale. Par André Schaeffner. (Bibliothèque musicale.) Pp. 406 + 32 plates. (Paris: Libr. Payot, 1936.) 50 francs.

A COMPREHENSIVE account of the musical instruments and their distribution has been wanted for a long time by ethnologists and others, so this work on the simpler musical instruments by M. Schaeffner is very welcome. The author admits that it is not exhaustive; it is evident that he has done his best to cover the ground, but as might be expected, specialists in certain areas are acquainted with instruments that are not alluded to by Schaeffner. For example, there are on the Sepik River, New Guinea, drums without a tympanum which are struck on the ground or on the surface of water. Fig. 2 is drawn from a photograph which shows a *sede* lying on the ground, so Schaeffner supposed that it was played while resting on the ground, but it is played only on vessels, *lakatoi*, while on the great trading expeditions, *hiri*, of the Motu peoples. The remarkable *temes naainggol* of Malekula, described by Deacon, have also been overlooked.

The author begins with "origines corporelles": singing and other sounds are produced by the mouth and its parts, but the mouth may also act as a resonator in playing the musical bow or the jew's harp. Hand-clapping, striking various parts of the body with the hands and tapping the Adam's apple to produce a tremolo, and stamping with feet are primitive methods for the production of music or rhythm, of which definite appliances may be regarded as extensions. These are innumerable, but the author has contrived to describe or refer to a very great number, and the variations and affinities of the main types are clearly stated. The author criticizes the groupings of Hornbostel and Curt Sachs and gives in an appendix an elaborate classification of his own. This recognizes: (1) Instruments with a solid vibrant body (*a*) not susceptible of tension, (*b*) flexible, (*c*) susceptible of tension, either a cord or a membrane. (2) Instruments directly dependent upon air vibration or wind instruments. There are also chapters on organology of the theatre; on instruments derived from, or associated with, work and play; instruments employed in religion and magic; the evolution of music; primitive polyphony; evolution and diffusion of instruments.

While admitting the provisional utility of the stratigraphy of Curt Sachs in which he reconstructs, layer by layer, the successive diffusion of instruments across the world, to which Hornbostel had made corrections in details so far as Africa is concerned, Schaeffner points out that there is a danger in linking material objects such as musical instruments with a chronology, itself hazardous, of phenomena of social organization which do not yet admit of a uniform interpretation. He agrees with R. H. Lowie who says, "In this department of culture, as in others, contacts with other groups are significant: African music excels because of the Negro contacts with Egypt, India and Indonesia. The Negro deserves credit for adapting and using his instruments, but not for creating them" ("An Introduction to Cultural Anthropology", 1934, p. 208).

Owing to the absence of an index, it is rather difficult to find an account of any particular instrument; also it would have been a help if the legends of the photographs had references to their respective pages, and if references to pages had been added to the classification in the appendix to this excellent book. A. C. HADDON.

Wild Nature's Day

By Frances Pitt. (The 'Greenjacket' Books.) Pp. 200+27 plates. (London: Sir Isaac Pitman and Sons, Ltd., 1936.) 3*s*. 6*d*. net.

MISS FRANCES PITT has done great service for her generation, in her endeavours to show the entrancing interest to be derived from the study of birds and beasts in their native wilds. There are very few who can compare with her in her ability to captivate those who have a kindly feeling for these creatures, but little or no time for first-hand observations of their ways. In this, her latest book, she has, we venture to think, surpassed all her previous efforts. Herein she presents the creatures of her choice as they are to be found during morn, noon and night. Even those who may claim to have more than a passing knowledge of the birds and beasts she describes will find something new that is worth knowing about their ways.

From a book as full of charm as this, it seems impossible to choose passages for special mention; for once the attempt was made whole pages would have to be quoted. Of the three parts into which the little volume is divided, perhaps the first and the last will be most enjoyed, since few of us are energetic enough to rise at daybreak, as Miss Pitt has a habit of doing, to note the gradual awakening of the birds; and the homeward journeys of creatures such as the badgers! Again, few of us are enthusiastic enough to stay out, when night has fallen, to watch the habits of bats and badgers, and others which hunt while the world sleeps; or to find out where the birds "go to bed"!

This is a book professedly written for boys and girls—we would add 'old, and young', for it is surely one of the best of its kind ever written. In a way that few other natural history books have ever done, it will arouse an interest that will last a lifetime.

W. P. P.

Index Generalis 1937:

the Year-Book of the Universities, Libraries, Astronomical Observatories, Scientific Institutes, Museums, Academies, Learned Societies. Issued under the direction of Dr. R. de Montessus de Ballore. Pp. vii+BE232+US232+F180+2500. (Paris: Masson et Cie., 1937.) 275 francs.

THE new edition of this annual handbook, indispensable to universities, research institutes, libraries, etc., maintains the high standard achieved by the previous edition. Nearly two thousand pages are devoted to the constitution of the universities, technical institutions and other educational establishments throughout the world. Such information contains the officers, professors (with their subjects), number of faculties and students, etc. This is followed by more than seven hundred pages describing the constitution, staffs, etc., of astronomical and other observatories, museums, academies, institutions and learned societies. Valuable information concerning the most important libraries is also included. Altogether there are 6,500 entries.

Appended is a useful list of men of science and others who wish to exchange their publications with other workers in the same field. This list has been extended. A list of publishers is given; but the section dealing with Great Britain, at any rate, is of little value, for several well-known publishers are omitted. A new feature in this edition is a list of Nobel laureates since the foundation of the prizes in 1901. The index of names contains 95,000 entries, which make reference an easy task.

This volume, as a book of reference, is invaluable to workers in all branches of academic life.

The Engineer's Year-Book of Formulæ, Rules, Tables, Data and Memoranda for 1937:

a Compendium of the Modern Practice of Civil, Mechanical, Electrical, Marine, Gas, Aero, Mine and Metallurgical Engineering. Originally compiled by H. R. Kempe and W. Hanneford-Smith. 43rd. Annual Issue, revised under the direction of L. St. L. Pendred. Pp. lxi+xiv+2676. (London: Morgan Bros. (Publishers), Ltd., 1937.) 31*s*. 6*d*. net.

WE welcome the forty-third edition of this annual. The editor has picked out the sections on machine tools, metallurgy, aeronautics, paints and varnishes for revision, and the names of the contributors are a surety for the accuracy of the information given. We are so familiar with this work that we have long ceased to consider its unwieldiness. But it is an outsize in handbooks, and so it is probable in the future that it will split into two or more volumes, suffering what physicists call atomic disintegration.

The editor tells us that the forty-second edition is sold out and that this is not due to the astuteness of the publisher in estimating the probable demand or because intensive sales methods are used. He infers that because it goes well it gives the kind of information the purchaser needs. A survey of the book shows that his deduction is probably correct. The descriptive sections, a useful feature of this year book, contain full particulars of various products of a number of engineering firms.

Leçons de zoologie

Par Prof. M. Prenant. Prochordés: Amphioxus, Tuniciers. (1. Ascidies). Pp. 71+3 plates. 15 francs. (2. Pyrosomes), (3. Doliolides), (4. Salpes), (5. Appendiculaires). Pp. 49. 12 francs. (Actualités scientifiques et industrielles, 379, 380.) (Paris: Hermann et Cie., 1936.)

THE Protochordates have been dealt with in a general way by Prof. M. Prenant in these two brochures. *Amphioxus* and the simple and compound Ascidians in one (No. 379) and *Pyrosoma*, the Salps and the Appendicularians in the other (No. 380). Each is a straightforward and well-illustrated account of the animals indicated in the title, prepared in the light of present-day knowledge. Both are well indexed and after each group is a select bibliography of most important monographs and recent memoirs relating to it. The numerous illustrations are all in the form of text figures and quite clear. The two publications constitute a useful addition to a well-known series.

Montserrat and the West Indian Volcanoes*

By Sir Gerald Lenox-Conyngham, F.R.S.

ABOUT the beginning of 1934, Montserrat began to be troubled by earthquakes and tremors. They became very severe and numerous in May and again in December. In 1935 they were worse still; much damage was done to buildings and naturally a great deal of anxiety was engendered in the minds of the inhabitants. In the autumn of 1935, the Governor received a petition from the leading members of the population praying that steps should be taken to determine, if possible, whether there was danger of a volcanic eruption.

This anxiety was very natural, for by the inhabitants of that region the terrible events of 1902 are well remembered. In that year on May 7 the Soufrière of St. Vincent burst into eruption and on the following day Mt. Pelé in Martinique did so too. From both of these volcanoes there poured what the French have called a *nuée ardente*, and what other observers have called the "Great Black Cloud". That from Mt. Pelé swept down upon the town of St. Pierre with such violence and such deadly effect that in a few minutes the whole town and its 30,000 inhabitants were destroyed. In St. Vincent the death roll was not so great because, fortunately, there was no large town in the area over which the cloud flowed.

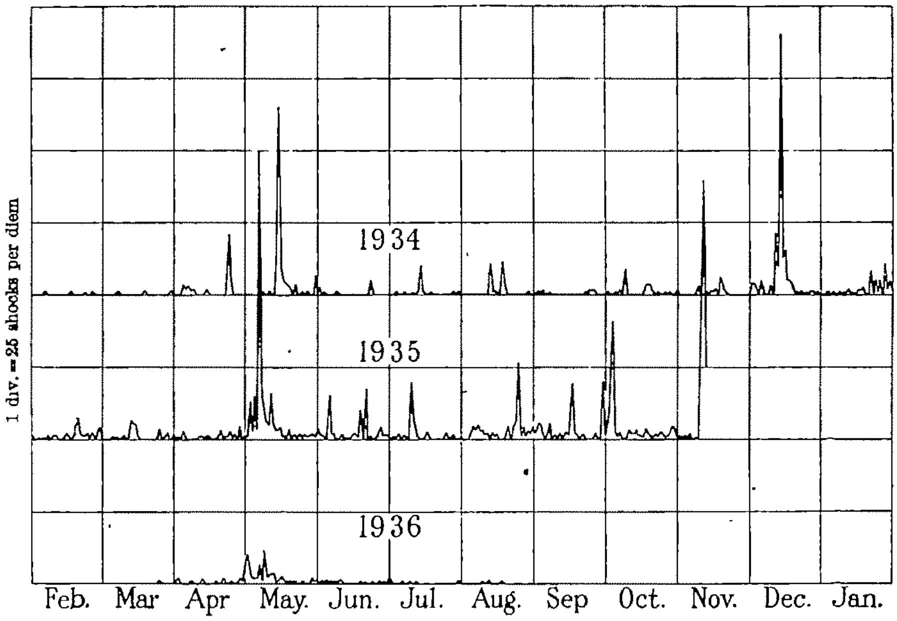

Fig. 1.

NUMBER OF SHOCKS PER DIEM.

The island of Montserrat is wholly volcanic. It contains no less than six volcanic cones; of these four lie more or less in a straight line running from north to south and give the island that serrated appearance which is the origin of its name.

The only map of the island is one made by the Hydrographic Department of the Navy in 1867. A recent geological survey of the island, made under great difficulties because of the absence of an accurate topographical map, shows that the most recent of the volcanic cones is the one called Soufrière Hills or Chance's Mountain, which dominates the town of Plymouth. The island was discovered by Columbus in 1493 and was first colonized by the British in 1632. We know that there has been no volcanic eruption in the island since it has been known to Europe, and from the evidence of the erosion that has taken place since the last eruption we may conjecture that that eruption belonged to a much earlier date. But the island has undoubtedly in the past been the scene of repeated volcanic outbursts, and as we know nothing at all of the causes which determine the time and place of an eruption, it would be extremely rash to assert that there will never be another, and certainly the experiences through which Montserrat had passed had been very alarming. Fig. 1 gives the daily number of tremors from February 1934 to November 1935 and again from March to August 1936. As many as 100 were recorded in one day in May 1935, and three other days were nearly as bad, so that the people of Montserrat had ample cause for apprehension.

The result of the petition mentioned above was that the Governor referred the matter to the Colonial Office and that the Colonial Office consulted the Council of the Royal Society. It was decided to send out an expedition consisting of a geologist and a physicist to see what they could find out. The geologist selected was Mr. A. G. MacGregor, of the Geological Survey, and the physicist was Dr. C. F. Powell, of the University of Bristol. An invitation was also sent to Dr. T. A. Jaggar of the Volcano Observatory of Hawaii asking him to visit Montserrat and give the members of the expedition the benefit of his great experience. This invitation he accepted. He paid his visit during the months of May and June and made a valuable report. The island was also visited several times by Mr. Perret. He is a volcanologist of long experience who has been spending a part of each year since 1929 in Martinique, observing the course of events since the eruption of September 16 of that year. Mr. Perret has made several very helpful reports.

---

* From a Friday evening discourse delivered at the Royal Institution on March 12.

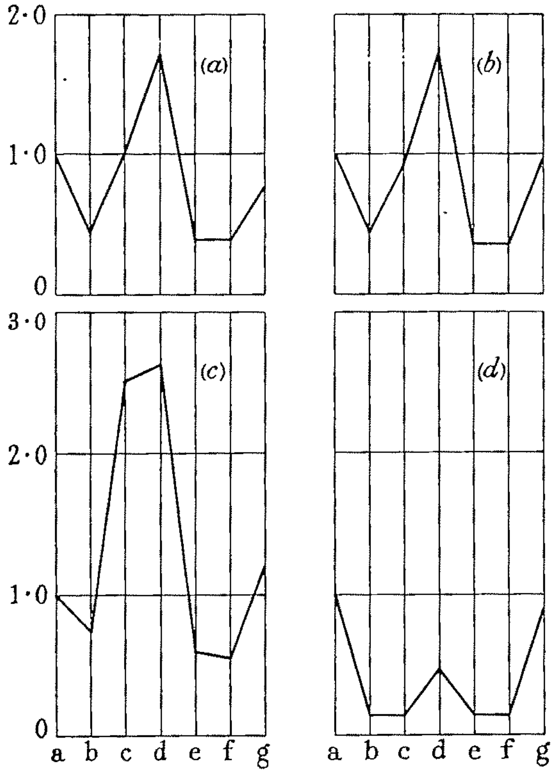

Fig. 2.

It is worth noting that there is a recurrence of activity in May of each of the years 1934, 1935 and 1936. This may be accidental, for three years do not constitute a long enough period for the establishment of a cycle, but it may be noted that the eruptions of 1902 also began in the month of May, so that there is some evidence of an annual crisis. Unless, however, one can connect a cycle which seems to be indicated by the observations with a physical cause, it is necessary to be careful, and only the most unimpeachable evidence derived from long periods of observation ought to be accepted.

Some careful and trustworthy observers are convinced that a lunar period, similar to that which is to be discerned in the tides, is to be observed in the behaviour of volcanoes, and the action of these tidal forces has sometimes been described as 'trigger action.' That seems an inappropriate term. The essence of a trigger action is that the application of a small force of one kind releases a large force of a different kind. But the action of tidal forces would be to produce a small increase —or diminution—of pressure of the same kind as that to which the crust of the earth is already subjected. There is no question of the release of a different kind of force. To call the effect of such a force as the tidal one a 'last straw' effect is legitimate. It is similar in action to the proverbial last straw. The character of the 'last straw' is its smallness. It does not have any effect unless the load which has already been imposed has very nearly overcome the strength of the 'camel's back'. These tidal forces are small; they will not produce any visible effect unless the pre-existing stresses are on the point of causing a fracture. If then it can be established that there is a cycle of earthquakes corresponding with the tidal period, it is strong evidence that at all times fracture is very nearly but not quite taking place. In the case of Montserrat, the evidence of an annual cycle is much too weak at present for it to be safe to venture on any inferences.

The Royal Society Expedition left England early in 1936 and was equipped with a number of Jaggar shock-recorders and a Wiechert seismograph. The shock-recorders were designed by Dr. Jaggar, mentioned above. They are simple, satisfactory instruments, not very sensitive but well adapted for recording the sharp, local shocks which were likely to occur. These instruments were in Dr. Powell's charge, and his plan was to erect the shock-recorders at a number of places well distributed over the island so as to obtain information as to the relative severity with which the shocks were felt in the several localities, and thence to deduce the whereabouts of the epicentres.

Dr. Powell made use of his instruments as follows: he noted first that the distribution of amplitude for shocks coming from the same focus should be constant and independent of the individuality of the recording instruments. Thus, taking the amplitude of the movement recorded at a selected station as unity, the amplitude at each of the other stations will be expressed by its ratio to this standard amplitude. If these ratios are plotted, as in Fig. 2, where the ordinates are the ratios and the letters represent the stations, they form a pattern, and it is reasonable to suppose that all shocks emanating from the same focus will produce the same pattern.

Then to determine the position of the focus which corresponds to a given pattern, we assume that the amplitude of the waves produced by an earthquake decreases inversely as the distance from the focus. We can estimate the position of the focus corresponding to each of the patterns. The results are shown in the map (Fig. 3). The open circles represent the positions of the epicentres and the shaded ones the positions of the instruments. The epicentres all lie on a belt which crosses the island from south-west to north-east and is rather less than four miles wide.

It is difficult to form any idea of what was going on during the long period of 30 months, during which these frequent tremors occurred. The nature of one of the great tectonic earthquakes, such as that in California in 1906, or in India in 1934, is in general outline clear enough. But these long-continued series of volcanic shocks, with their periods of greater and less activity, are manifestations for which it is hard to account.

Looking at the West Indian region as a whole, there is no apparent system in the way in which eruptions and earthquakes occur. Below is a list of the more important of such events since the beginning of the nineteenth century compiled for the most part by Dr. Jaggar.

1802	Eruption	Guadeloupe
1812–14	Eruptions	St. Vincent
1831	Submarine Eruptions	near Barbados
1837–38	Eruptions	Guadeloupe
1842	Greater Earthquake affecting many islands	
1843	Submarine Eruption	near Guadeloupe
1851	Eruption of Mont Pelé	Martinique
1867	Great sea wave after submarine earthquake. Felt in Grenada and elsewhere	
1880	Activity	St. Vincent & Dominica
1897–99	Earthquakes	Montserrat
1902–04	Eruptions	St. Vincent & Martinique
1906	Earthquakes	St. Lucia
1907	Earthquake	Jamaica
1918	Earthquake	Puerto Rico
1929–32	Eruptions Mont Pelé	Martinique
1930	Series of Earthquakes	Nevis
1934–36	Series of Earthquakes	Montserrat

No system or sequence is discernible in these events, but the records are not very complete and they are not based on instrumental observations. If each island were equipped with a recording instrument, there would be a fair prospect of movements being detected which might otherwise escape notice, and these movements might give some clue to the way in which the forces, whatever they are, traverse the region.

There is another line of approach to this problem. It seems to be generally agreed that the Lesser Antilles are oceanic islands which have grown as submarine volcanoes from the broad top of a tectonic arc. The islands are therefore only symptoms. The volcanoes have their origin in the tectonic arc, and it is its nature and origin that are of interest to us.

The West Indian island arc is by no means the only one of its kind, and no one who has made the comparison can fail to be struck by the general similarity between the West Indian and the East Indian island arcs. This similarity, however, would not be of much interest if it were not for one special circumstance. It is this. It was a Dutchman, Dr. Vening Meinesz of the Dutch Geodetic Commission, who invented the only successful method, so far, of making determinations of gravity at sea, and these East Indian islands are Dutch possessions. It was not unnatural, therefore, that Dr. Vening Meinesz should see, in the waters surrounding these islands, not only an interesting region for a gravity survey, but also a region in which he would be among his own people and where he could rely on being allowed to call where he liked. His method can only be carried out on a submerged submarine, and as a submarine is essentially a ship of war, foreign harbours cannot be visited without some preliminary negotiation.

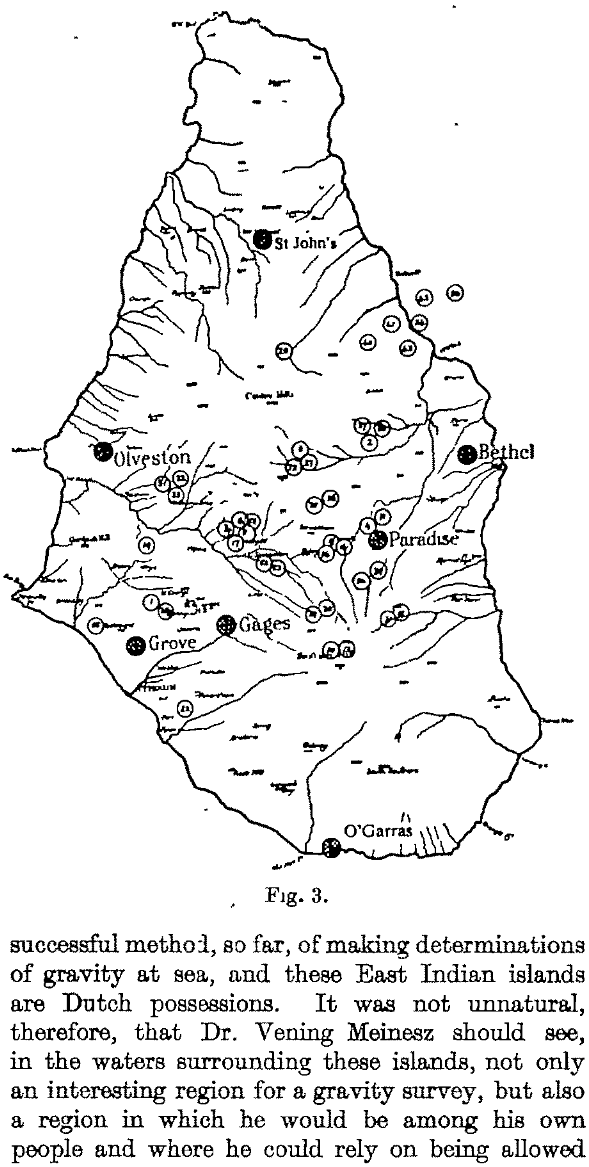

Fig. 3.

Dr. Meinesz made a number of cruises among these islands in the years 1929-30 and determined the value of gravity at more than two hundred places. He discovered, quite to his surprise, that there is a continuous belt of negative gravity anomaly on the convex or outer side of the island chain. This line of negatives tells us something about the structure. It shows that along that line the less dense outer layer of the crust has been pressed downwards and has displaced the denser rock below. Dr. Meinesz has drawn a diagram (Fig. 4) to illustrate his conception of the state of things. In the diagram the less dense material of the outer layer of the crust is displacing the denser magma, and it is only by the exertion of continuous pressure that this state of things can be made to persist. If the pressure were withdrawn, gravitational forces would push this root up until it was in floating equilibrium, and the gravity anomalies would disappear. The gravity anomaly then shows that there is a state of strain, that there is abnormal lateral pressure directed across the line of negative anomaly, which runs parallel to the island arc.

It is much to be desired that a similar gravity survey should be made of the West Indian region, and it is very satisfactory to learn that this has been undertaken by the United States Navy.

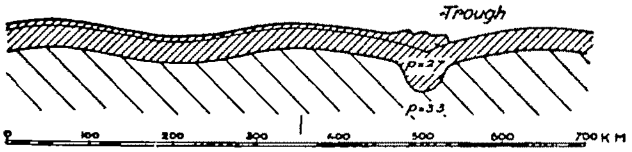

Fig. 4.

There is another feature of these island arcs which I think deserves attention, and that is their curvature. In July 1903 a paper by Mr. Philip Lake entitled "The Circular Form of Mountain Chains" appeared in the *Geological Magazine*. In it and subsequent papers by the same author, the cause and nature of these arcs were discussed, and what follows is largely derived from them.

Whenever we see an arc of a circle on the surface of a sphere we cannot fail to perceive that it is the intersection of a plane with that surface, and when the arc is marked by a mountain chain or by a festoon of islands—by marks, that is to say, of force of some kind—it is natural to think of the plane as a thrust plane and to imagine that forces acting in that plane have been the cause of the formation of the islands or mountains as the case may be. If this is so, then there must have been some slipping of the matter above the plane on the matter below it. There will be a fault, and the dip of the fault can easily be shown to be equal to the radius of the circular arc.

Mr. Lake examined the arc formed by the Himalayas and suggested that its form is due to the fact that there is a thrust plane at its base. It is easy on a globe to find the position of the centre, or, to speak more correctly, the pole of the arc, and then to measure the distance from the pole to the arc in degrees of great circle. Making this measurement, Mr. Lake found that the radius was 14°, and concluded that this must be the dip of the basal thrust plane. In 1919, Mr. C. S. Middlemiss made the first actual measurements of the dip of the Main Boundary fault of the Himalayas. He found it to be between 12° and 15°. This Main Boundary Fault is the principal line of separation of the older tertiary rocks of the Himalayas from the younger rocks that lie along the foot of the mountains.

One cannot doubt that the great earthquakes which from time to time cause so much devastation in the Gangetic plain are the result of movement of the newer rocks on the older or of fracture resulting from the pressure of the one upon the other, but we need not expect that those earthquakes will find expression in movement along the visible faults, for the movement is much deeper. Mr. Middlemiss, for example, writing of the great earthquake of April 5, 1905, says that the earthquake was due to "a sudden rupture or release of strain occurring . . . where the strain was specially great owing to resistances to the well established forward march of the over-thrusting foot of the Himalayan range".

It appears, then, that the mountain arc is due to the overthrusting of the advancing range: that the real seat of the thrust is deep down under the alluvium, that the form of the arc is determined by what is going on down in those depths and that therefore, since the radius of the arc is 14°, the dip of the plane along which the thrust is taking place should also be 14°. It is probable that there are a number of fault planes parallel to the fundamental one, and since at the place where we can examine the matter we find a dip of 14°, we may reasonably infer that the fundamental thrust plane has this inclination also, which corroborates the evidence given by the radius of the arc.

Until, however, we know the results of the gravity survey made by the U. S. submarine, further conjecture on the West Indian problem would be premature. If by gravity observations we can arrive at some idea of the position of the point at which the front of the overriding rock is in contact with the old overridden rock, and if we know the slope of the plane which divides the one from the other, and if also we can form some estimate of the amount of deformation of the dense magma below by the intrusion of the lighter material which has been forced down into it, we shall arrive at some kind of picture of the structure that lies below these volcanic arcs, and that will at any rate be a step in the right direction.

Recent Crystallography*

By Sir William Bragg, O.M., K.B.E., P.R.S.

ALTHOUGH some of the considerations already discussed are admittedly provisional, they show how the knowledge of protein structure is steadily increasing, how, in fact, the examination of the structure can be looked on as a branch of crystallography. The X-ray methods furnish measurements of distances and angles which suggest the possible forms of the proteins in space, forms which must obey certain geometrical conditions. Some of these are carried over from examinations of other organic molecules ; others are derived from direct X-ray measurements of the proteins themselves. It then becomes of great interest to connect the physical form with biological properties.

Quite recently a remarkable discovery by Dr. Stanley, of the Rockefeller Institute at Princeton, has shown that a certain virus, which causes disease in tobacco plants, is a protein. Its composition falls within the protein limits already quoted. Its molecular weight has been found by Svedberg to be of the order of 17 millions. It has reactions to polarized light which show that it is crystalline, and that the great molecule is needle-like in form. The conclusions follow from the fact that a solution of the virus shows when disturbed the effect known as 'streaming double refraction'. When minute crystals are suspended in a liquid medium they normally point in all directions. If the suspension is examined between crossed Nicol prisms, the field is dark. But if the suspension is so disturbed that the particles in any region are arranged to point in the same direction, or at least so that on the average they point more in one direction than another, the whole behaves like a single crystal, and illumination appears in the field. The very beautiful display of this effect by a suspension of the needle-like crystals of vanadium pentoxide has been known for some time.

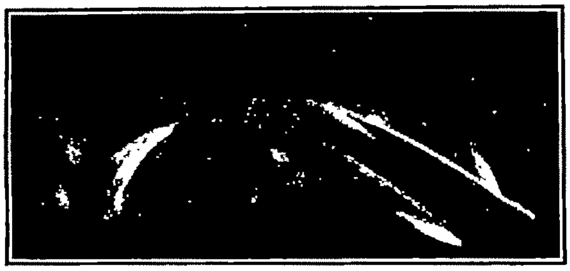

Fig. 3.

WAKE OF A GOLDFISH SWIMMING IN A DILUTE SOLUTION OF PROTEIN FROM A SAP INFECTED BY TOBACCO VIRUS, OBSERVED BETWEEN CROSSED NICOLS.

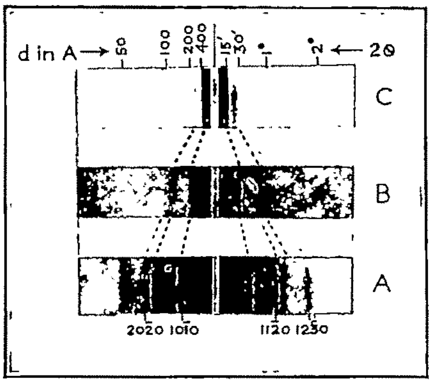

Fig. 4.

X-RAY PATTERNS OF DRY GEL (A), WET GEL (B), AND 13 PER CENT SOLUTION (C).
(By courtesy of J. D. Bernal.)

The disturbance of the liquid by stirring of any kind produces whirlpools in which layers of the liquid slide past one another in shearing motion. Any long rigid particle lying across the general direction of flow is moved forward more slowly at one end than at the other. In consequence it tends to set itself parallel to the stream. But the conditions are unstable. If it continues its rotatory motion past the position of parallelism, it undergoes a further rotation of 180°. On the whole, however, one may expect the periods of parallelism to be much longer than those in which the particle lies across the stream. This effect can be shown by allowing glycerine to move along a narrow glass tube, carrying with it short lengths of a fine fibre.

In a whirlpool, therefore, the rod-like crystalline particles tend to set themselves tangentially to the whirl. A beautiful illustration of this effect is given in Fig. 3, which is reproduced from a communication to NATURE[2], by Bernal and others. A small fish is moving in a virus suspension between crossed Nicols. The movements of the tail leave vortices behind them and the crystalline needles of the virus follow the movement of the liquid in spirals approximating to circles. The field shows bright spots arranged at the corners of a cross ; because the line of movement makes an angle of 45° with the planes of the crossed Nicols at four points.

---

* (*Continued from p.* 866.)

Bernal and his collaborators have been able to obtain X-ray diffraction photographs of the virus. These are shown in Fig. 4. The pure virus in a suspension stronger than 2 per cent separates into layers which are sharply distinguishable. One of these (*B*) is "an extremely soft gel well orientated and with much higher birefringence, 0·007, than the liquid.. The outer part of this wet gel shrinks by 50 per cent and forms a layer of higher refractive index, but lower birefringence, 0·003". These two layers give respectively the photographs *A* and *B* of Fig. 4. Photograph *C* is obtained from a 13 per cent solution in which the crystals are orientated by flow along a narrow tube. A similar set of lines is found in the three cases, indicating a hexagonal arrangement, such as would naturally be found in an arrangement of long rods put side by side. In *A* they are at a distance, rod to rod, of 152 A.; in *B*, 210 A. In *C* the distance is more vaguely defined, as one would expect, and ranges from about 300 A. to 470 A.

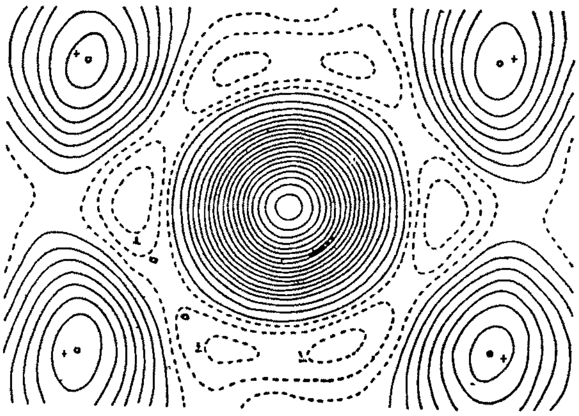

Fig. 5.

THE CENTRAL PORTION OF A MOLECULE OF NICKEL PHTHALOCYANINE, SHOWING THE ELECTRON DENSITY OF THE NICKEL ATOM, PROJECTED ON THE PLANE OF THE DIAGRAM.

(J. M. Robertson.)

Besides these evidences of regularity in the side to side placing of the molecules, there is evidence in other photographs of much narrower spacings, which do not vary with the condition of the material and the arrangement of the molecules side by side. They refer obviously to regularities within the molecule. The length of the spacing is given as $3 \times 22{\cdot}2 \pm 0{\cdot}2$ A., a result in close agreement with measurements of Wyckoff and Corey on the tobacco virus and on a variety of it known as the *aucuba* virus. It is very remarkable that this virus, though a crystalline protein, appears to be capable of multiplying itself and of generating an anti-body, and to be liable to mutation.

Brief reference may be made to a few other examples of the development of crystallography by means of the X-ray methods, supplemented now by the methods of electron diffraction.

Dr. J. M. Robertson has investigated in much detail the nickel phthalocyanine. The shadow picture contains a beautiful display of the electron distribution in the nickel atom, projected upon the plane of the diagram. The central part of the molecule containing this atom and its immediate surroundings is shown in Fig. 5. The contour lines of the nickel atom are drawn so that from line to line there is a difference of two electrons per square Angström unit. In the other part of the figure the difference is one electron per unit area. The accuracy is high, and the figure must give a fairly accurate representation of the distribution of the electrons in the nickel atom. It can be represented closely by an empirical formula of the form Ae^{-kr^2} where r is the distance from the centre of the atom.

Applications of the new crystallographic tools to the study of practical problems of metallurgy and engineering have been numerous and important. As an example may be taken the study of the effects of cyclic stress upon a mild steel, recently described by Gough and Wood[3]. It is well known that metal structures can in certain cases be fractured by a sufficient application of intermittent or cyclic stresses; that, to use the technical term, they become fatigued. Gough and Wood establish the important point that "the application of cycles of a safe range of stress (strain) is unable to cause *progressive* damage to the state

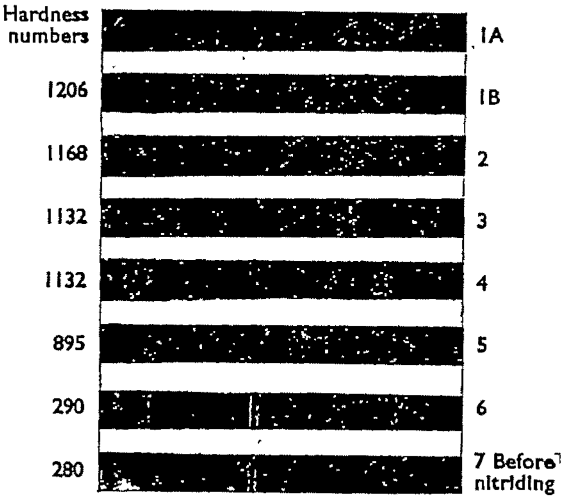

Fig. 6.

X-RAY PHOTOGRAPHS TAKEN AT DIFFERENT DEPTHS IN A NITRIDED STEEL: THE FIGURES ON THE LEFT REFER TO THE HARDNESS. THE TOP FIGURE SHOWS THAT AT THE VERY SURFACE IRON NITRIDES HAVE BEEN FORMED.

(From the Report of the National Physical Laboratory, 1933, by permission of the Controller, H.M. Stationery Office.)

of the structure". The X-ray powder photographs of a piece of mild steel show no change during the imposition of cyclic stresses of 9 tons to the square inch, up to 10^7 repetitions. This is just within the safe range of stress. But when the stress is increased to 9·7 tons, which lies outside the safe range, there is a gradual change. The X-ray photographs show that the crystal grains are being broken up into powder consisting of far smaller crystal portions, and the structure fractures after about half a million cycles or so. Thus the progressive deterioration of the specimen takes place only when a certain safe load has been exceeded.

In this case the appearance of the X-ray photograph indicates the condition of the material. In a number of instances the photographs are now used in this way; the spacings of the crystal planes which are determined by the positions of the lines are not in question. Thus the series of photographs of Fig. 6 shows the conditions of a steel at various depths below the surface when ammonia at 500° C. has been passed over it. The diffuse character of the lines shows that the crystallites have been broken up. Close to the surface the fragments are so small that the material is practically amorphous. At the surface itself iron nitrides have been formed. The physical effect is a very marked hardening, as indicated by the hardness numbers in the diagram. The whole effect is contained within a quarter of a millimetre from the surface. These photographs are due to Dr. G. Shearer, of the National Physical Laboratory.

Diffuseness in the photograph may also be caused by any distortion of the lattice, such as occurs when a specimen is severely strained. This is found to be the case, for example, in the operation of wire drawing.

One of the most remarkable developments of X-ray crystallography is the advance in our knowledge of the internal condition of an alloy. The 'order-disorder' theory, as it is termed, has been especially studied in the Manchester laboratories, and has been described by W. L. Bragg[4].

Obituary Notices

The Right Hon. Lord Conway

LORD CONWAY, whose death on April 18 at the age of eighty-one years will be widely regretted, was a many-sided man. He had very varied interests. He was a professor and lover of art; he was a collector of art treasures; he was a politician; and he was a mountaineer. In no one line did he achieve real greatness. But he always and everywhere derived keen enjoyment out of life and he had the knack of conveying his enjoyment to others. Everybody liked him.

Perhaps it was in mountaineering that Conway found his chief enjoyment. Among the mountains his love of beauty found an ample field. As he climbed not as an exercise in gymnastics but in order to get the real feel of the mountains from close contact with them, he was able to develop his true fundamental self among them. He climbed the Alps "from end to end". But not content with them, he ventured farther afield and travelled among the supreme mountains of the world. In the full maturity of his climbing powers, he set out for the Himalaya in search of a fairly accessible 25,000 ft. peak. He was not the first from Europe to attempt Himalayan peaks. Some forty years before him, the Schlagentweits had climbed to at least 22,000 ft. and more recently Graham had reached 23,000 ft. on Kabra. But Conway's expedition to the Karakoram Himalaya was the first to direct the attention of the world to the glory of the Himalaya. He chose as the scene of his operation what is perhaps the finest part of the whole range—the region of the Karakoram Himalaya. For sheer sublimity of natural beauty it is unsurpassed. It lies beyond the forest-class zone of lower altitudes. Here there is nothing but bare rock and ice and purest snow. All is of sternest grandeur. There are several peaks of 24,000 ft. and 25,000 ft. in height, four of 26,000 ft., one of 27,000 ft. and supreme over all, K_2—28,250 ft.—second only to Mount Everest itself in altitude but far nobler in aspect.

Here Conway was in his element. It was not in his nature to strive after records on climbing. Indeed, years after, he took no interest in attempts on Everest; to climb a mountain merely because it happened to be the highest in the world made no appeal to him. What really moved him in the Karakoram region was the glory of the mountains. There where even the valley bottom was higher than the summits of the Alps—there surrounded by peaks of towering grandeur—he felt his whole soul uplifted towards them. He entered into the spirit of the mountain. In his writings he tried to convey something of his own enjoyment; and he was successful. Others responded to the call. Since his time, German, Italians, and French, as well as other British have gone there too.

Conway was also a man of deep religious feeling. No such true lover of beauty, and especially of sublime mountain beauty, could help being religious. He could not help being in love with such beauty, which aroused in him such an ecstasy of delight.

FRANCIS YOUNGHUSBAND.

Sir George Hart, K.B.E., C.I.E.

WE regret to record the death, at Barberton, Transvaal, on April 16, of Sir George Hart, formerly inspector-general of forests to the Government of India. Born on April 14, 1866, he was educated at St. Paul's School and at the Royal Indian Engineering College, Coopers Hill. He joined the Indian Forest Service in 1887, and was posted as assistant conservator in the Punjab, where he served until 1906, when he was transferred to the Central Provinces as conservator of forests. Two years later, he went to Bengal as conservator, and in 1910 was re-transferred to the Central Provinces as chief conservator. In 1913 he was appointed inspector-general of forests, in which capacity he served until 1921, when he retired. He was made C.I.E. in 1911 and K.B.E. in 1919. On retiring from India he settled down at Coolmore, in the White River district, Transvaal, where he stayed until his death.

Hart's service covered an important and interesting period in the history of Indian forestry. Before his arrival, much pioneer work had been done in the way of saving the forests from destruction. Reservation and demarcation had made progress, and protective measures had been begun. Working-plans operations were being extended, and he took his full share in pushing on this important work. In the Punjab, large irrigated plantations, rendered necessary by the demand for timber and fuel in the canal colonies, were in process of creation and development.

At the time Hart assumed the duties of inspector-general of forests, forestry was more centralized under the control of the Government of India than it became some years later; and although the functions of the inspector-general were purely advisory, he was able to exercise considerable control in working-plans matters, and thus on the management of the forests in the different provinces. He also exercised direct administrative control over the Forest Research Institute and College at Dehra Dun. Hart's term of office as inspector-general covered the War period, when the forest department's energies were taxed to the utmost in supplying timber for military purposes.

Hart will be remembered as a sound practical administrator rather than as a scientific investigator, for although his interest in science was by no means negligible, his strong point was the confidence which his personality inspired both in his Government and in those serving under him.

Prof. A. W. Borthwick, O.B.E.

THE death on April 19 of Albert William Borthwick, in spite of the fact that he had been in ill-health for some time, came as a shock to his many friends and admirers, perhaps more especially in Scotland, where he played a not inconsiderable part in the progress of forestry; which cause had no more ardent or more enthusiastic supporter during the past quarter of a century.

Prof. Borthwick was born on October 16, 1872, the third son of the late Mr. W. H. Borthwick, of Crookston and Borthwick Castle, Midlothian, a descendant of ancient stock, dating back to the Scottish barony of 1452, now extinct or dormant. He was educated at Madras College, St. Andrews, and the University of St. Andrews, where he graduated B.Sc. in pure science, obtaining first-class honours in botany, physiology and mathematics. After graduation, he proceeded to Germany and passed four years in studying forestry and forest botany at Munich. On returning to Scotland he was appointed assistant to the professor of botany, the late Sir Isaac Bayley Balfour, and lecturer in plant physiology, at the University of Edinburgh. On the inauguration of the degree of B.Sc. in forestry at the University in 1910, Dr. Borthwick was appointed lecturer in forest botany. At the same time he lectured on forestry in the East of Scotland College of Agriculture and also gave the course in this subject at the Royal Botanic Gardens.

Dr. Borthwick did not remain at the University. In 1915 he was appointed chief advisory officer to the Board of Agriculture for Scotland. During the War, he served on the committee for the Supplies of Home Timber. From the Scottish Board, on the inauguration of the Forestry Commission in 1920, Dr. Borthwick was transferred to the Commission as chief research and education officer, and visited Canada as one of the representatives of the Commission at the meeting of the Empire Forestry Conference held in that Dominion. In May 1926, he was appointed to the new chair of forestry established in the University of Aberdeen, which he held to his death.

Borthwick's chief and best work was probably done in research. He was a first-class forest botanist, and this enabled him to play so great a part in advising private owners of woodlands, whose requirements at the time were chiefly on that border line where sylviculture and forest botany came into close affinity. He had another invaluable trait. He possessed in a high degree the power, at conferences of experts and others with varying interests in forestry, of assembling opposed points of view and placing them in a light which resulted in a general acceptance.

For some years Prof. Borthwick edited the *Journal* published by the Royal Scottish Arboricultural (now Forestry) Society, and was president for a period. He was unmarried. He was made an O.B.E. after the Great War.

E. P. STEBBING.

WE regret to announce the following deaths:

Mr. J. H. Field, C.S.I., formerly director of observatories in India, on May 19, aged sixty-four years.

Prof. Albert Griffiths, formerly professor of physics in Birkbeck College, University of London, on May 24.

Prof. S. H. Langdon, F.B.A., professor of Assyriology in the University of Oxford since 1919, on May 19, aged sixty-one years.

Mr. J. D. Rockefeller, senior, founder of the Rockefeller Institute for Medical Research and of the Rockefeller Foundation, on May 23, aged ninety-seven years.

News and Views

Prof. A. M. Carr-Saunders

As announced in NATURE of May 22, p. 896, Prof. A. M. Carr-Saunders, Charles Booth professor of social science in the University of Liverpool, has been appointed director of the London School of Economics and Political Science. The University of Liverpool showed remarkable discrimination fourteen years ago in selecting for the newly established chair of social science a trained scientific investigator with an alert and critical mind. Prof. Carr-Saunders had already earned a considerable reputation as a writer and scholar of distinction, and his books bore evidence of wide reading and culture. Before he went to the Liverpool School of Social Studies, it was a small and struggling department: he leaves it one of an important group which has become the School of Social Sciences and Administration, attracting students and visitors from all parts of the world. He has done more than any single man to arouse Government and people to the importance of the impending decline in population and to call for more serious investigation into its causes. He has also been a pioneer in the study of the professions: What standards should be required of those who enter them, and what ties should bind the members of a group together? In seeking answers to such questions, Prof. Carr-Saunders has shown himself to be no dilettante theorist. Under his inspiration, a new Division of Public Administration has been added to the Liverpool School, and it is turning out a steady stream of young men who in the future will occupy important administrative posts in the country. There is indeed scarcely any department of university life upon which he has not left an enduring mark. The secret of this amazing capacity to play a leading part in so many important affairs lies in a habit of steady and systematic application to everything he takes in hand.

Linnean Society: Awards and Elections

AT the anniversary meeting of the Linnean Society of London held on May 24, the president, Dr. W. T. Calman, delivered his presidential address entitled "James Eights, a Pioneer Antarctic Naturalist". The Linnean Gold Medal was presented to Dr. F. F. Blackman, formerly reader in botany in the University of Cambridge. In making the presentation, the president said that the modern period of research on some of the fundamental problems of plant physiology began with the medallist's "Experimental Researches in Vegetable Assimilation and Respiration" in 1896. These "Researches", carried on with the aid of students, now number twenty-one, and recently a new series, "Analytical Studies in Plant Respiration", has been added. In 1905 Dr. Blackman published a paper entitled "Optima and Limiting Factors", which is a landmark in the study of the influence of external factors on physiological processes. His work, characterized by the invention of accurate and ingenious experimental methods, has influenced, directly or indirectly, a great part of the research on plant physiology in Great Britain, and it has been given to few to have so deep an influence on a whole generation of workers. The Trail Award of the Society, "to encourage study that throws light on the substance known as Protoplasm, or the physical basis of life" was made to Dr. C. F. A. Pantin, Harding lecturer in zoology in the University of Cambridge, for his work on the mechanism of amœboid movement showing that the protoplasmic changes involved are fundamentally similar to the processes which go in cilia and in muscle. The following were elected officers of the Society for the year 1937–38: *President*, Mr. John Ramsbottom; *Treasurer*, Francis Druce; *Secretaries*, I. Henry Burkill and Martin A. C. Hinton; *New members of Council*, I. Henry Burkill, Miss M. L. Green, Dr. H. S. Holden and Prof. F. E. Weiss.

Foreign Members of the Linnean Society

THE following have been elected foreign members of the Linnean Society: Dr. Reinhard Dohrn, director of the Marine Biological Station, Naples. Dr. Dohrn is the son of the founder of the station, the reputation and popularity of which have steadily increased under his government. The Great War and the years which succeeded threatened its existence; its survival was entirely due to the self-sacrificing enthusiasm of Dr. Dohrn. Dr. Herman Augustus Spoehr, director of sciences at the Carnegie Institution's Division of Plant Biology, Stanford University, California. Dr. Spoehr's work has been mainly on the physiology of plants, his first researches being concerned with photosynthesis; his text-book on "Photosynthesis" published in 1926 is of high merit. His study of photosynthesis and the nutritive problems of cacti opened up several lines of research; he has published results on the colloid behaviour of plant protoplasm, the reduction of carbon dioxide by ultra-violet light, growth and imbibition, the chemistry of leaf pigments, together with a series of papers on respiration—some of them in collaboration with other workers. Prof. Erik Anderson Stensiö, director of the Riksmuseets Paleontologiska Avdeling, Stockholm, distinguished for his researches upon Old Red Sandstone fishes. His success has been largely due to his admirable fertility in inventing new methods for the development of these fossils: by such means he gained a great deal of information about the nervous system, blood supply and mucus circulation in these ancient organisms, all matters of great morphological significance.

Prof. Nils Everherd Svedelius, director of the University Institute at Uppsala, who has been associated with the University for more than forty years. He is well known for his contributions to the knowledge of the taxonomy, morphology and life-histories of marine algæ, the majority of these being written in German and English. As befits a successor of Linnæus in so old a University as Uppsala, he has written on the history of botany. His writings on the taxonomy and morphology of various flowering plants include studies on *Juncus*, Gentianaceæ and the so-called sea grasses. He has travelled extensively in pursuit of his special interests in geographical distribution, algæ and cytology. He is treasurer of the Swedish Linnæan Society. Dr. Richard Woltereck, for many years professor of zoology in the University of Leipzig, and until recently director of the Zoological Institute, Ankara, Turkey. Prof. Woltereck has a world-wide reputation as a limnologist. He organized and was the first director of the Freshwater Biological Station at Lunz in Austria, and by his editorship of the *Internationale Revue der Gesamtes Hydrobiologie und Hydrographie* since its commencement in 1908, has rendered invaluable service to all students of aquatic biology.

Royal Astronomical Society: New Associates

THE recent election of Dr. B. Lyot and Profs. J. H. Oort and Shajn as associates of the Royal Astronomical Society is significant not only as a recognition of their contributions to astronomy, but also as emphasizing the modern tendency of the Society to give this honour for research rather than for official position alone. Ever since Lockyer's and Janssen's successful detection of prominences without an eclipse, the possibility of the daylight photography of the solar corona has exercised astronomers. It has, however, been left to the young French astronomer Lyot, one of the new associates, working with exquisitely designed though inexpensive apparatus, to detect the corona on the Pic du Midi by its polarized light, then afterwards to photograph the inner bright part, and finally to obtain high dispersion spectra in the visible and infra-red of its characteristic emission lines of unknown origin. Fully as distinguished in another field is Prof. Oort of Leyden. In addition to his numerous contributions to stellar statistics, he is especially known for his quantitative formulation of Lindblad's hypothesis of galactic rotation, a formulation which in Oort's hands has greatly clarified our ideas on stellar motions and our knowledge of the structure of the galactic system. Prof. Shajn is a representative of the growing school of young Russian astronomers. His work has been characterized especially by its versatility; he has made contributions of outstanding merit in fields so wide apart as the disturbing action of the earth on meteoric orbits and the study of complex multiplets in stellar spectra.

Museums of India

THE report on the museums and art galleries of India issued by the Museums Association, of which an account appears in another column of this issue of NATURE (see p. 934) will stand in the eyes of future generations as a grave indictment of an administration which has failed to appreciate the cultural needs of the population at large, outside a narrow view of educational and social policy, and at the same time has neglected its opportunity, not to say its duty, to preserve permanently a fully representative record of the material culture of the past and present civilizations of India. To say this is not to ignore either the many difficulties, financial and other, which have confronted past administrators as obstacles in the way of formulating a coherent and comprehensive policy for the provision of museums, or the efforts towards more adequate provision, such as were made under Lord Curzon, or the valuable system of local museums instituted recently in connexion with the work of the Archæological Survey; but these, except in the instance of the last-named, are matters of past history.

IT is the absence of any sign of a progressive attitude towards the provision and utilization of the museum as an instrument in raising the general cultural level, admittedly low, of the population of India that constitutes the gravest element implicit in the indictment. The lack of adequate financial support, as well as of systematic allocation of the funds available, the inadequacy, in every sense, of staff, and the failure to formulate any general policy, which would conduce to efficiency of management within, and consultation and co-operation outside the four walls of the individual museum, grave defects as they may be, are no more than symptoms of apathy, no doubt an unconscious apathy, in the higher authorities responsible for direction and control. Now that attention has been directed forcibly to this far-reaching lapse in the public policy of India, it will be the duty—and a test—of the new regime to set about its remedy with all dispatch.

Antiquities from Essex at the British Museum

AN exhibition of exceptional interest of antiquities from Essex is now on view in the Prehistoric Gallery of the British Museum (Bloomsbury). The objects were found on a site between Rainham and Upminster, about fourteen miles from London Bridge, and are lent by Mr. G. T. Carter with the permission of the Newbury Park Gravel Pit Co., from the excavation works of which they were derived. In part, the great interest of the discovery lies in the fact that all periods of prehistoric and early historic culture in Britain are represented from palæolithic to Saxon times. The finds include palæolithic hand-axes, polished neolithic axes of a type common in the Thames area, pottery of the Early Bronze Age, the most noteworthy example being a small beaker, of reddish ware, decorated with bands of lines and dots, and pottery of the Late Bronze Age, the Early Iron Age and the period of Roman occupation. This succession in evidence of occupation on one and the same site on the estuary of the Thames is of peculiar interest to the archæologist; but the remarkable feature of the discovery is the occurrence of Saxon relics, and more especially of a cemetery, at this point. This is the first instance recorded of a Saxon settlement in the marsh and forest area of south Essex between London and Southend. The absence of cinerary urns and signs of cremation point to a probable date not prior to the sixth century B.C. Nor does there appear to be any ground for connecting this settlement with the East Saxons of the coastal area from Colchester to Ipswich. It is thought to belong to an estuarine Saxon group scarcely differing from that on the north coast of Kent. The finds, of which a selection is shown, include two remarkable curved drinking horns of olive green glass, both broken, but one of which it has been found possible to reconstruct, bronze brooches and rings, wooden buckets with bronze mounts, shield bosses, spearheads, a sword of iron and Roman coins, pierced for use as pendants. The levels of the pit in which the antiquities were found are shown in photographs. The finds will be on view for two months.

Tuberculosis in Wild Voles

TUBERCULOSIS among wild animals living in their natural state is almost unknown, and the announcement by Dr. A. Q. Wells of the Bureau of Animal Population, Oxford, of the discovery of this disease among wild voles is of great interest and, it may be, importance (*Lancet*, 1, No. 21, 1221, May 22, 1937). Since last February, Dr. Wells has found in 134 voles caseous lesions, like those of tuberculosis, in which bacilli having the peculiar and characteristic 'acid-fast' staining reaction of the tubercle bacillus were present. In addition, cultures made from the lesions yielded growths resembling those of the tubercle bacillus, and guinea pigs inoculated with the material developed tuberculosis. The voles had been sent from seven different stations in the British Isles, so that the disease seems to be wide-spread among these animals and not a chance occurrence in one locality, and the existence of tuberculosis among them may be of importance in the spread of this disease to domestic animals and to man. The wild vole (*Microtus agrestis*), known as the short-tailed field or grass 'mouse', is a common rodent in meadows, and several sub-species occur in the north. It is of interest in respect to ecology and distribution, for the animals are subject to wide fluctuations in population, increasing over a period of three to four years, and then suddenly decreasing to a low figure in one or two months, and it has been surmised that the decrease may be caused by the occurrence of some epidemic disease among them.

A New Ceramic

EXPERIMENTAL work extending over a period of years at the Mellon Institute of Industrial Research has resulted in the production of a new laboratory table top material made of a porous, non-warping ceramic body that is impregnated with bituminous substances and then heated under special conditions to form coke in the pores. Unusually high resistance to thermal shock is imparted to the material because artificial cordierite, a mineral that has a very low thermal expansion, is used in making up the ceramic body. The material can be polished to velvety smoothness, and possesses sufficient hardness to resist scratching and abrasion, ample structural and impact strength, denseness that prevents absorption of liquids, resistance to solvent action and chemical attack, and the ability to withstand perfectly the effect of rapid heating and cooling. Thus "Kemite", as it has been called, has none of the disadvantages of the commonly used table-top materials. While Kemite was developed primarily as a laboratory table-top material, it can be fabricated in complicated shapes of large size without joints. When high resistance to thermal shock is not required, cordierite is not used in the ceramic body, and ware made from the non-cordieritic body is called 'Karcite'. Kemite should prove useful for vats, tanks and other apparatus, because of its resistance to the action of chemicals and its low thermal expansion. In the electrical industry, the basic body, properly impregnated, can be employed for switchboard panels, specially moulded parts and complex shapes, and as an insulating material.

Broadcasting an Eclipse

THE National Geographic Society, Washington, claims that the broadcasting of a series of programmes before and during the eclipse of June 8–9 from one of the (normally) uninhabited islands of the Phœnix Group will be the first instance of broadcasting "from a desert island". It will not be the first eclipse which has been broadcast from an eclipse camp, as Dean Eve broadcast to Canada the total eclipse of 1932 from a camp at Magog, but it will probably be the first time when an announcer and two engineers of a national broadcasting company have formed part of an eclipse expedition to a foreign country. The scientific details of the eclipse expedition arranged by the National Geographic Society were published in NATURE of April 24, p. 698; but one or two points of general interest may be added here. The duration of totality at noon will be longer than at any other eclipse over a stretch of 1,238 years; unfortunately, it takes place at a point 1,500 miles from the nearest land. A special self-bailing boat will be used to take the equipment ashore, and the U.S. naval seaplane tender will stand by the island during the expedition's stay ashore. A complete black and white motion picture record of the eclipse will be made and colour 'movies' may also be taken.

Development in the Arctic

RECENT economic developments in the Siberian Arctic lands bear some testimony to Mr. V. Stefansson's contention of a 'friendly arctic'. A paper in the *Geographical Journal* of April by Mr. H. P. Smolka describes some of the recent Soviet schemes on the Yenisei, Khatanga and other rivers, where a few years ago a little native fishing and hunting were the sole interests. Igarka, 600 miles up the Yenisei, and some distance north of the Arctic Circle, is now a city of 14,000 inhabitants with well-built timber houses and timber roads. There are schools, theatres and other amenities, and the whole town is flood-lit in winter. The one interest is timber, which is exported by the river in late summer. Work goes on all the year round, and the inhabitants rarely suffer from cold even with temperatures of − 35° C. A modern port is being built. Norilsk, farther north than Igarka, is being built for new coal mines on the Pyasina River and is being connected by a 70-mile railway to its port of Dudinka, another new growth 400 miles up the Yenisei River. Nordvik, at the mouth of the Khatanga River, in nearly lat. 70° N., is an even more amazing growth. It was started last year as a town for the new salt mines. With these urban growths there are developing also experiments in arctic agriculture. In lat. 68° N., onions, radishes and cabbages have been grown in the open, and tomatoes, cucumbers and asparagus in hothouses. Experiments are being made in growing vegetables in electrically heated and lighted subterranean chambers, the current being provided by windmills.

Central Water Advisory Committee

THE Minister of Health has appointed a Central Water Advisory Committee under the chairmanship of Lord Milne. The following have been appointed to serve on the Committee: Sir Albert Atkey, Mr. E. T. L. Baker, Mr. H. K. Beale, Mr. R. Beddington, Mr. John Chaston, Lieut.-Colonel E. J. Clarke, Mr. A. E. Cornewall-Walker, Sir Robert Doncaster, Lieut.-Colonel A. P. Heneage, Capt. R. T. Hinckes, Mr. S. R. Hobday, Mr. J. E. James, Mr. E. W. Cemlyn Jones, Sir David Owen and Mr. D. Verity. The Committee's terms of reference are to advise the Government Departments on questions relating to the conservation and allocation of water resources; on any questions which may be referred by the Departments with respect to matters arising in connexion with the execution of, or any proposed amendment of, the enactments relating to water; and to consider the operation of the enactments relating to water and to make to the Government Departments such representations with respect to matters of general concern arising in connexion with the execution of those enactments, and with respect to further measures required, as the Committee thinks desirable. Any communications concerning the work of the Committee should be addressed to the Secretary, Mr. A. Titherley, at the Ministry of Health.

American Tour of British Research Organizations

BETWEEN twenty and thirty American executives and bankers are making a rapid tour of Great Britain, France and Germany to study European research organization at first hand lasting from May 24 until June 30. The tour is being arranged under the auspices of the American National Research Council by Mr. Maurice Holland, the director of the Division of Engineering and Industrial Research of the Council. The tour in Great Britain has been arranged in co-operation with the Department of Scientific and Industrial Research, and visits will be made to the National Physical Laboratory, the Building Research Station and the Fuel Research Station. The party will also spend a day at the Shirley Institute, the headquarters of the Cotton Research Association at Didsbury, and will be able to visit the laboratories of the Leather, the Boot and Shoe and the Rubber Research Associations. The party is visiting the research laboratories of several large firms. A visit is also being paid to the Cavendish Laboratory at Cambridge. During the tour, about thirty-five laboratories will have been visited, covering eighteen different fields of industrial research.

Scottish Science and the Industrial Revolution

FOR his inaugural address as regius professor of natural history in the University of Aberdeen, delivered on April 21, Prof. L. Hogben took for his subject "The Theoretical Leadership of Scottish Science in the English Industrial Revolution". In this he showed how eminent men trained in the biological sciences stimulated the progress of chemistry and physics, and thereby influenced the growth of various industries at the end of the eighteenth and the beginning of the nineteenth centuries. The Industrial Revolution was, of course, bound up with the development of the textile, iron and coal industries, but more especially with the introduction of the steam engine and to a lesser extent with the rise of the chemical industry. The part played by Watt and Murdock in the improvement of the steam engine is well known, but Prof. Hogben showed how to men such as Joseph Black, James Keir, John Roebuck and Francis Horne—all graduates of medicine—can be traced some of the advances in industry. Black's connexion with Watt is familiar to all, while Roebuck not only endeavoured to assist Watt, but also had a principal share in establishing the Carron Iron Works, and was a pioneer in the manufacture of sulphuric acid. The address contains some interesting notes on the early members of the Royal Society of Edinburgh when James Hutton and John Playfair were leaders of Scottish science, and it recalls that Hutton, though generally regarded as one of the fathers of modern geology, yet is also remembered as the founder of a manufactory for sal ammoniac. In concluding his review of the subject, Prof. Hogben said that "The restricted class basis of English education could not supply the theoretical leadership which its industrial expansion demanded. It had to rely largely on a fund of personnel from Scotland".

Flood-lighting and Broadcasting during the Paris Exhibition

DURING the Paris Exhibition, it has been arranged that some four hundred monuments and buildings in the smaller villages of France and in the open country will be flood-lighted by five mobile units carrying flood-lighting equipment. Each of the lorries will carry generating plant, and will be manned by three men. It will carry ten spotlights of 3 kilowatts each and ten floodlights of 1½ kilowatts.

There will also be apparatus for the production of chemical smoke, as well as an amplifier and a loud speaker installation permitting lectures or music, which will be broadcast during the displays. According to the *Electrician* of May 21, all the services of the Government broadcasting system will be transferred to the radio pavilion at the Paris Exhibition. For this purpose, three large studios with mixing desks and control room, two smaller studios for speakers and announcers, and a television studio are being installed. There will also be an installation for the registering and rebroadcasting of records. The installations will be entirely enclosed in glass so that the public can see all the equipment in operation and yet all risk of noise or crowds interfering with the operations will be prevented. As the stations are broadcasting all day, it will be possible for the public to see at least some part of the installation in operation at all hours of the day. The lighting tour has been organized to extend until the end of October. The general control of the whole system will be centred in a room near the entrance to the pavilion. It will have connexions with both French and foreign stations. In many places, the local authorities are being asked to provide flood-lighting for other buildings of interest.

Modern Applications of Psychology

DR. C. S. MYERS, in a paper before the Royal Society of Arts on March 10 on "Industrial Psychology and the Modern World", began by showing the indebtedness of this most recent application of psychology to the educational and medical applications that had preceded it. The field covered by it is very wide, since it is concerned with all grades of occupational life, with industrial relations, personnel management and with all the environmental conditions that can hinder or further the happiness, health and efficiency of those engaged in industry. Already the pioneer work done in England is being developed and adapted by many other countries. By a scientific study of individual differences and of the requirements for success in particular occupations, the industrial psychologist has been able to develop a technique which enables him to direct an entrant into the occupation for which he seems most fitted, and also to help the employer to select from a number of applicants those with the fundamental requirements. The young person is thereby saved from much futile groping and the attendant sense of failure. When, however, the right selection has been made, it becomes necessary to train the beginner in the right methods, instead of letting him pick up for himself methods that might be good or might be bad. In this field, the industrial psychologist has made a special study of the best movements and methods of work that should be taught, and of the suitable methods of teaching the required movements. He has also much to offer to management, and could prevent the unnecessary friction resulting from those in authority having more knowledge of the machinery and of the materials involved than of the human beings for whom they are responsible.

British Speleological Society

ALTHOUGH the British Speleological Society has been in existence for a brief period only, having been formed at Derby two years ago, there is evidence that the organization has fulfilled its purpose and indeed has prospered exceedingly under the presidency of Sir Arthur Keith in the announcement that it proposes to institute a museum of its own. The object of the Society is to co-ordinate the exploration and excavation of caves and potholes, and as was evident from the very successful first conference held at Buxton last year, much useful work on these lines has already been done. The Society now proposes to take over Cragdale, Settle, as its headquarters, and a museum will be formed to house photographs of underworld scenery, geological specimens, human and animal remains as well as other relics of cave man. A speleological library will also be formed and housed in the new headquarters. The second Speleological Conference and exhibition of photographs, surveys, prehistoric remains, geological specimens, etc., from British and foreign caves will be held in the University of Bristol on July 23–26. Further information can be obtained from the deputy secretary of the British Speleological Association, University College, Hull. On July 27–August 8, there will be a conducted tour to some of the more important caves in Germany, Austria and Czechoslovakia. Further information can be obtained from Mr. C. R. Hewer, Tallin, Kiriku Poik 4, Estonia.

Charles Darwin and the Modern Theory of Tropisms

PROF. BOYSEN JENSEN's new book upon "Growth Hormones in Plants" directs attention to the conclusion drawn by Charles Darwin "that when seedlings are freely exposed to a lateral light, some influence is transmitted from the upper to the lower part, causing the latter to bend". Prof. N. Cholodny writes to the Editor from Kiev pointing out that a passage from "The Power of Movement in Plants" (1880) refers to the localization of phototropic sensibility in the tip of the coleoptile of *Phalaris* in these terms: "These results seem to imply the presence of some matter in the upper part which is acted on by light, and which transmits its effects to the lower part". Prof. Cholodny points out that this passage might be interpreted as foreshadowing modern theoretical interpretations of the same tropic phenomenon as due to the movement of growth-regulating substances or hormones.

Health Resorts of Britain and the Empire

THE British Health Resorts Association has issued its official handbook for the current year ("British Health Resorts: Spa, Seaside, Inland". Edited by Dr. R. Fortescue Fox. With a Foreword by Sir Kingsley Wood, Minister of Health. London: J. and A. Churchill, Ltd. 2*s*. 6*d*. net). The handbook follows the lines of previous editions, but the whole of the material has been carefully revised, and new information is given in a condensed form as regards the sunshine and rainfall in many resorts. A valuable chapter on climatology has been contributed by

Mr. L. C. W. Bonacina. A synopsis of the attractions offered by British resorts during the 'invalid's winter' is included, and the principal spas and climatic resorts of the British Commonwealth overseas are also mentioned.

Fauna of the North Sea

LIEF. 30 of "Die Tierwelt der Nord- und Ostsee" contains a mixed bag of monographs, dealing with nemertine worms (Hermann Friedrich), halophile and halobionic Hemiptera (Håkon Lindberg), and the Anthozoa included in the sea anemones and Alcyonaria (F. Pax). Short diagnoses of the characters of species and of their distribution are supplemented by accounts of the morphology, physiology, development, variation and biology in general of larger groups. Parts of this ambitious and very useful work have been appearing at the rate of slightly less than three a year since 1925, and there are still many to follow.

A Forestry Herbarium

THE forestry herbarium collected by the late Prof. A. H. Henry, formerly professor of forestry at University College, Dublin, has now been made available for inspection and reference at the Botanic Gardens, Glasnevin, Dublin. The collection comprises more than nine thousand specimens and was presented to the nation by Mrs. Henry on the death of her husband. Since then, Mrs. Henry has devoted much time to the work of classification and arrangement so as to make the collection readily accessible for reference purposes. This unique collection is a tribute to the memory of a distinguished scholar, and the admirable arrangement accomplished by Mrs. Henry enhances that tribute.

The Cerne Giant: A Correction

It would appear that the announcement of the impending sale of the Cerne Giant (see NATURE, May 22, p. 876) was due to a misunderstanding. The sale of Cerne Abbas property, which will take place on June 16, will include the remains of the famous Abbey and an Elizabethan farm-house; but the well-known hill 'carving' is not for sale. The Cerne Giant, we are reminded by the secretary of the National Trust, was presented to the National Trust in 1920 by Mr. A. E. Fox Pitt-Rivers and an endowment provided for its upkeep by Sir Henry Hoare.

The Night Sky in June

ON June 21 at 20^h, the sun enters the sign Cancer (the summer solstice). In the latitude of London, the length of night from sunset to sunrise is then only $7^h\ 26^m$. The moon is new on June $8^d\ 20{\cdot}7^h$ and full on June $23^d\ 23{\cdot}0^h$. On June 8, a total eclipse of the sun takes place and is visible in equatorial regions of the Pacific, but although the path of totality (of maximum breadth 153 miles) extends over nearly one hundred degrees of terrestrial longitude, there are very few possible land sites to which expeditions can be sent. The duration of totality at the noon point is $7^m\ 4^s$, making this eclipse the longest that has occurred for more than a thousand years. Of the planets visible during June, both Mercury and Venus are morning stars. On June 6, Mercury is at greatest elongation 24° west, and Venus at greatest western elongation (46°) on June 27. Venus is in conjunction with Uranus on June 18 at 11^h, when the two planets are separated by 2·7°. Mars is conspicuous low in the south as the sky darkens. The planet decreases in brightness from magnitude $-1{\cdot}7$ to $-1{\cdot}2$ during the month. On June 20 at 10^h, Mars is in conjunction with the moon and is then only 0·1° northwards of the latter (geocentric positions). The circumstances produce an occultation of Mars by the moon, the phenomenon not, however, being visible from the northern hemisphere. Jupiter rises in the evening twilight and souths about 2^h in the middle of the month; on June 25 at 21^h it is in conjunction with the moon. Saturn rises soon after midnight in mid-June; on June 4 at 2^h conjunction occurs with the moon. The apparent breadth of the minor axis of the ring system is $3''$–$4''$. At 22^h in mid-June, the bright star Regulus is nearing the western horizon; Arcturus has passed the meridian, Spica and Antares are low down in the south, while Vega, Altair and Deneb are conspicuous eastwards of the meridian. The maximum of the Scorpiid meteors is due about June 4, the radiant point being nearly midway between α Scorpii (Antares) and η Ophiuchi. An ephemeris for the comet Grigg-Skjellerup, is given in the *B.A.A. Handbook* as follows:

	R.A.	Dec (N.)
June 4	$9^h\ 36{\cdot}3^m$	23° 36′
„ 8	10 04·5	25 53
„ 12	10 36 0	28 02
„ 16	11 10 3	29 51
„ 20	11 46·8	31 10
„ 28	13 01·2	31 50

Commonwealth Fund Fellowships

THE following appointments, among others, to Commonwealth Fund fellowships tenable by British graduates in American universities for the two years beginning September, 1937, have been made: Dr. J. B. Bateman, King's College, London, and University of Cambridge, to the University of Pennsylvania, in biophysics; D. M. Douglas, University of St. Andrews, to the University of Minnesota, in medicine; J. A. Downes, Imperial College of Science and Technology, London, to the University of California, in zoology; Dr. R. N. Jones, University of Manchester, to Harvard University, in chemistry; N. F. McGrath, University College, Oxford, to the University of Chicago, in political science; Wilfred Merchant, Corpus Christi College, Oxford, to the Massachusetts Institute of Technology, in engineering; Dr. Arthur Porter, University of Manchester, to the Massachusetts Institute of Technology, in physics; H. O. Puls, University of Reading, to the Massachusetts Institute of Technology, in physics; Dr. F. D. Richardson, University College, London, to Princeton University, in chemistry; Dr. B. V. Rollin, Wadham College, Oxford, to the University of California, in physics; J. D. Spillane, University of Wales, to Columbia University, in medicine; B. D. White, Queen's College, Oxford, to the University of Minnesota, in economics; D. M. de R. Winser, Corpus Christi College, Oxford, to Yale University, in physiology.

THE following has been appointed to a fellowship tenable by candidates from the British Dominions: I. F. G. Milner, University of New Zealand, and New College, Oxford, to the University of California, in international relations. The following have been appointed to fellowships tenable by candidates holding appointments in Government service overseas: W. I. B. Beveridge, University of Sydney, of the Council for Scientific and Industrial Research, Australia, to the Rockefeller Institute, Princeton, in veterinary science; W. J. Blackie, University of New Zealand, of the Department of Agriculture, Fiji, to Yale University, in biochemistry; E. T. A. Edwards, University of Sydney, of the Department of Agriculture, New South Wales, to the University of Wisconsin, in agriculture; Robert Galetti, Balliol College, Oxford, of the Indian Civil Service, Madras, to Stanford University, in agriculture; B. W. Wilson, University of Cape Town, of the Railways and Harbours Administration, South Africa, to the University of Illinois, in engineering. The following have been appointed to fellowships tenable by candidates holding appointments in the Home Civil Service; J. L. Blake, University College, University of London, of the Patent Office; R. N. Quirk, King's College, Cambridge, of the Mines Department.

Announcements

SIR FREDERICK GOWLAND HOPKINS has been elected president of the Association of Scientific Workers in succession to Dr. W. H. Eccles.

WE regret the omission from the Coronation Honours list printed in NATURE of May 15 of the name of Mr. C. S. Wright, director of scientific research at the Admiralty, who was appointed C.B.

DR. SYDNEY SMITH has been appointed works manager at the Wellcome Chemical Works, Dartford, the chief works of Messrs. Burroughs Wellcome and Co. It will be recalled that the previous holder of this post was Dr. H. A. D. Jowett, who met his death in a motor-car accident last August (see NATURE, Aug. 29, 1936). Dr. Smith has been associated with Messrs. Burroughs Wellcome and Co. for twenty-three years, and during that time has made highly important contributions to the study of the alkaloids of ergot and the glucosides of *Digitalis*.

IT is announced in *Science* that at the dinner of the U.S. National Academy of Sciences held on April 27, the following medals were awarded: James Craig Watson Medal to Prof. E. W. Broun, emeritus professor of mathematics in Yale University, for his work on lunar theory; Henry Draper Medal to Dr. C. E. Kenneth Mees, director of the Research Laboratory of the Eastman Kodak Company, for his work on the theory and perfection of photographic processes and materials; Agassiz Medal to Prof. Martin Knudsen, professor of physics in the University of Copenhagen, for his work on physical oceanography; Mary Clark Thompson Medal to Prof. A. W. Grabau, professor of palæontology in the National University of China and chief palæontologist to the Chinese Geological Survey, for his work on Chinese palæontology.

THE centenary of the Liverpool Medical Institution will be celebrated on May 30–June 1, when Prof. R. E. Kelly will deliver a presidential address on surgery a hundred years ago, and the Hugh Owen Thomas and Robert Jones memorial library of orthopædic surgery will be opened.

A SESSIONAL meeting of the Royal Sanitary Institute will be held at Newcastle-upon-Tyne on May 28, when a discussion on the difficulties of nutritional assessment will be opened by Dr. H. E. Magee of the Ministry of Health, Dr. G. C. M. M'Gonigle, medical officer of health of Stockton-on-Tees, and Dr. J. C. Spence, honorary assistant physician to the Royal Victoria Infirmary, Newcastle-upon-Tyne.

AN International Congress of Medicine applied to Physical Education and Sport will be held in Paris on July 11–17 under the presidency of Profs. Carnot and Latarjet. The subjects for discussion will be physical education in and after the school period, education and control of sport, and incidents and accidents of sport. Further information can be obtained from Dr. Collet, 45 rue de Clichy, Paris.

AN International Congress on Occupational Diseases and Industrial Welfare will be held in Paris on June 1–6 under the presidency of Dr. V. Balthazard, professor of forensic medicine in the University of Paris. Further information can be obtained from the Secretary-General of the Congress, Dr. G. Haussen, Institut Médico-Légal, Place Mazas, Paris, XII^e.

THE seventh English-Speaking Conference on Maternity and Child Welfare will be held at the British Medical Association House on June 1–3 under the presidency of the Minister of Health, and will be attended by 600 delegates. Further information can be obtained from the Honorary Secretary, Miss J. Halford, Carnegie House, 117 Piccadilly, W.1.

PROF. LOWELL J. REED, professor of biostatistics in the Johns Hopkins School of Hygiene and Public Health, has been appointed dean of the school in succession to Dr. Allen W. Freeman.

THE headmaster of a boys' secondary school in London desires to obtain issues of NATURE regularly two or three weeks after publication, for use by his senior students. We shall be glad to know the name and address of any reader or subscriber who would be willing to supply such copies at a reduced rate.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 931.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Isotopic Weight of ^{12}C

IN my last letter[1] I directed attention to the uncertainty in the value of this constant, which is particularly unfortunate as it is the most important sub-standard in the determination of isotopic weights by the mass-spectrograph. Since then I have been to great pains to make further measurements of it by as many independent methods as possible. The following is a summary of all my results in the order in which they were obtained.

(*a*) The doublet $O—CH_4$ was measured using a cylindrical discharge tube and varying the position of the doublet on the spectrum to minimize the effect of any local disturbances in the fields of the instrument. The results were used in fixing the fundamental isotopic weights[2].

(*b*) These measurements were repeated using a large spherical discharge tube[1].

The objections to the use of the $O—CH_4$ doublet to determine the isotopic weight of carbon are: (1) It is so wide (more than 22 units of packing fraction) that the effect of uncertainty in the absolute value of the dispersion coefficient may be serious. (2) The value obtained is dependent to the extent of about one third on the isotopic weight of ^1H. (3) The fact that one line is atomic and the other molecular may possibly cause asymmetry.

(*c*) The analogous doublet $CO—C_2H_4$ was measured. This is not so easy or accurate, but eliminates objection (3).

(*d*) The fortunate occurrence on one plate of a particularly well-matched doublet $^{40}A—C_3H_4$ gave a useful check, for the values of the isotopic weight of ^{40}A show no serious discrepancy.

(*e*) The mass of ^{12}C was compared directly with that of ^{16}O by means of the close ratios $O{+}{+} : C \sim C : OH_2$ by artificial doublets made by applying electric fields in the ratio $3 \sim 2$. This is the method by which the packing fraction of ^{12}C was originally measured[3]. It reduces errors due to (1) and (2) each to about a third, but unfortunately the technical difficulty of controlling the intensity of the OH_2 line makes it somewhat unreliable.

(*f*) The ratio $O{+}{+} : C$ was now measured against $A{+}{+}{+} : A{+}{+}$. These artificial doublets were easier to produce, and gave very consistent results. The particles concerned are all atomic, the results are independent of hydrogen and of any reasonable error in the absolute dispersion coefficient as the ultimate difference is only 3 units of packing fraction.

(*g*) By long running with dry gases containing argon, the OH_2 line had been reduced to such an extent that three well-matched natural doublets $^{36}A{+}{+}—OH_2$ were obtained. In each of these the very faint intermediate line due to ^{18}O was clearly visible, enabling a provisional value for it to be found as given below. ^{36}A had already been paired with C_3, so that the packing fraction of C could be calculated from that of OH_2.

(*h*) As a further check, the ratios $^4He : C{+}{+} \sim A{+}{+}{+} : A{+}{+}$ were compared, there being no serious disagreement in the isotopic weight of He.

The accompanying table gives the mean values of the packing fraction of ^{12}C deduced from these experiments in estimated order of their reliability. My figures for the isotopic weights of hydrogen, helium and argon have been used in the calculations, and the appropriate small corrections for the mass of the electron have been applied in the case of artificial doublets.

	Method	Number of independent observations	Packing fraction of ^{12}C deduced
(*a*)	$O—CH_4$	14	2·96
(*b*)	$O—CH_4$	13	2·97
(*c*)	$CO—C_2H_4$	18	2·91
(*f*)	$O{+}{+} : C \sim A{+}{+}{+} : A{+}{+}$	15	2·91
(*g*)	$^{36}A{+}{+}—OH_2$, $^{36}A—C_3$	3,6	2·99
(*e*)	$O{+}{+} : C \sim C : OH_2$	18	3·11
(*h*)	$He : C{+}{+} \sim A{+}{+}{+} : A{+}{+}$	5	3·00
(*d*)	$^{40}A—C_3H_4$	1	3·0

These results justify the value 2·96 which I have been using, and enable its probable error to be reduced. The following are the values deduced:

Symbol	Packing fraction	Isotopic weight
^{12}C	2·96	12·00355 ± 0·00015
^{18}O	3·2	18·0057 ± 0·0002
^{36}A	−6·10	35·9780 ± 0·0010

Temperature Equilibrium of C-Neutrons

THE slow neutrons leaving a block of paraffin wax, containing a source of fast neutrons, mostly possess thermal energies. The existence of such thermal neutrons has been established by the discovery[1] that the temperature *T* of the paraffin has an influence on the activities induced in various elements. Since the neutrons penetrating a screen of cadmium do not show this effect[2], cadmium may be used to discriminate between the slowest neutrons (C-neutrons[3]) and the faster ones.

The dependence on temperature of the absorption of C-neutrons has been studied by a number of investigators[4]. If the C-neutrons are in thermal equilibrium with the paraffin, their absorption in boron, lithium and silver should be proportional to $1/\sqrt{T}$ because the capture cross-section for slow neutrons of these elements should be inversely proportional to neutron velocity (the $1/v$ law[5,6]). (In the case of silver the $1/v$ law has been checked experimentally[7].) While the results of Preiswerk and v. Halban[2] were not in direct disagreement with the $1/\sqrt{T}$ law, other investigators obtained definitely smaller variations with temperature than this law predicted.

TABLE 1

T	80°	195°	290°	415°
μ_T/μ_{290}	1·50±0·05	1·25±0·04	1	0·89±0·04
$\sqrt{(290/T)}$	1·9	1·22	1	0·84
μ_T/μ_{290} calc.	1·71	1·21	1	0·84

In an investigation of this question, we have obtained the relative values, given in the accompanying table, of the absorption coefficient μ of silver for C-neutrons emerging from a paraffin block at different temperatures. The neutrons were counted by a boron-lined ionization chamber connected to an amplifier and mechanical counter. At the three higher temperatures, the $1/\sqrt{T}$ law is seen to be nearly fulfilled; μ^{80}, however, is distinctly too small. For boron and lithium absorbers the values of μ^{80}/μ^{290} were found to be the same as for silver.

In discussing these results, the following points must be considered:

(1) The energy spectrum of C-neutrons includes—apart from the thermal neutrons—a tail of faster neutrons (tail neutrons) extending to the absorption limit of the cadmium screen ($\sim$ 1 eV.[4]).

(2) The H nuclei in the paraffin are very inefficient in slowing down neutrons below the lowest hydrogen oscillation energy, that is, below 0·1 eV. On account of this, the neutrons are crowded in the region below 0·1 eV. We may try to estimate this effect by treating the neutrons as if they were colliding with free particles of mass 14 (CH_2-nuclei).

(3) The number of collisions required to bring a neutron from 0·1 eV. down to room temperature is about ten (estimated according to ref. 2), and as many as ten more collisions are needed to bring it down to 80° K. On the other hand, the mean number of collisions suffered by a slow neutron before emerging from a paraffin block is about 100. (We obtained this figure by studying the influence of small amounts of boric acid on the intensity of neutrons slowed down in water under similar geometrical conditions to those in our temperature experiments.) It follows that neutrons spend a considerable part of their life between the cadmium absorption limit and thermal energy; correspondingly, a considerable fraction of the neutrons leaving a paraffin block have energies in this region. Therefore the C-group is inhomogeneous, especially at low temperatures.

(4) The mean life of neutrons in paraffin, if limited only by capture in the paraffin, is independent of temperature; it is not affected by the zero point oscillations of the protons.

Taking these points into account, we have calculated quite roughly the relative mean absorption coefficients of C-neutrons. While the exact theory of slowing down must consider collisions with bound protons, the present treatment using the idea of 'CH_2-nuclei' can at least be taken as illustrative of the trend of the results to be expected. Since the experimental results deviate from the $1/\sqrt{T}$-law in roughly the same way as the calculated ones (see Table 1.), we believe that our explanation is correct in principle and that there is no reason whatever to doubt the $1/v$ law as a result of such experiments.

The experiments are being continued and a detailed account is to appear soon.

Structure Types of Protein 'Crystals' from Virus-infected Plants

FURTHER work on preparations of proteins from virus-infected plants tends to confirm and extend the conclusions expressed in our previous letter[1]. We had there shown that both concentrated solutions of these proteins and the material prepared from them by drying gave orientated paracrystals. We have now succeeded in preparing the 'crystals' of Stanley and Wyckoff in an orientated form, after trying unsuccessfully a number of methods, such as flow orientation. The method finally used was that of forcing mother liquor out of the 'crystals' by centrifuging in an unglazed porcelain tube, in a saturated atmosphere. The resulting mush was orientated by rolling between glass slides, at 0° to avoid evaporation, becoming completely transparent in the process. It was mounted in a sealed brass case with bubble thin lindeman glass windows and examined by X-ray and optical methods without loss of water. It proved to be practically indistinguishable—in water content (50 per cent), optics and X-ray pattern at low and high angles—from the preparation previously called wet gel. On being allowed to dry, it likewise turns into a horny mass giving similar X-ray photographs to 'dry gel', though fainter and with slightly larger spacings, probably due to internal strain. The X-ray pattern obtained from the unorientated crystals shows all the main lines given by Wyckoff and Corey[2] for their crystals, and we have been able to assign all but four very weak lines on these photographs to definite spots given by the orientated gel. There can therefore remain little doubt that their 'crystals' are substantially identical with ours and with our previously described paracrystals.

As many deductions have already been drawn from the crystalline nature of these proteins, it is important to state precisely in what sense the word 'crystalline' should be used in respect of them on the basis of interpretation of X-ray photographs. Normally, crystallinity presupposes an indefinite repetition of identical units in three-dimensional space. These proteins appear not to possess this degree of regularity. The degree of regularity which seems to be the only one consistent with the X-ray evidence has thus far not been described, though it has been predicted theoretically as one of the types of liquid crystal. The long molecules of the protein are packed with a perfect hexagonal two-dimensional regularity at right angles to their length, but there is no evidence of regularity of molecular arrangement in the direction of their length. None of the reflections in directions other than at right angles to the molecular length is due to the packing of the molecules, but rather to regularities within them, as shown by the fact that such reflections persist unchanged when the molecules are in dilute solution. Lines observed by Wyckoff refer not to the regular packing of equivalent molecules but to regularities within the molecule. They can only be said to be evidence for crystallinity if by that it is understood that each molecule is itself a crystal. The relatively small lateral dimensions of the molecules, 150 A., can only permit of imperfect diffraction effects in these directions as shown by the diffuseness of the spots, while the great length of the molecule is indicated by the extreme sharpness of the reflections from planes perpendicular to its length. A complete interpretation of this intramolecular pattern has not yet been possible; but a rough survey indicates that the molecule is made of piles of submolecules of dimensions 22 A. × 20 A. × 20 A., somewhat smaller than the normal protein molecule, and themselves divided into nearly identical units with half these dimensions.

RELATIVE INTENSITIES OF INTERMOLECULAR REFLECTIONS OBTAINED FROM VARIOUS VIRUS STRAINS.

$h^2 + k^2 + hk$	$hkil$	Tobacco mosaic	Enation	Aucuba	Cucumber 3	Cucumber 4
1	$10\bar{1}0$	*s*+	*w*–*m*	*m*	*m*	*w*
3	$11\bar{2}0$	*s*	*s*	*s*	*m*	*w*–*m*
4	$20\bar{2}0$	*m*	*m*	*w*–*m*	*w*	*vw*
7	$21\bar{3}0$	*m*–*s*	*m*–*s*	*m*–*s*	*s*	*s*
9	$30\bar{3}0$	*vvw*	0	0	0	0
12	$22\bar{4}0$	0	*vvw*	0	*m*–*s*	*m*
13	$31\bar{4}0$					

The microscopic appearance of the Stanley 'crystals' is quite consistent with their liquid crystal character, for although fairly long, about 40 μ, they are extremely thin, about 0·4 μ thick, and have gently tapering ends. This is quite different from the prismatic or pyramidal forms of true protein crystals and more like the 'micro tactoids' observed in colloidal solutions of the fibrous type. On pressing they readily fuse together into a homogeneous mass, emphasizing their partially liquid nature. Their most probable internal arrangement is that shown in Fig. 1. This arrangement would also serve very well to explain the observations of R. J. Best[3] on the formation of mesomorphic fibres from infected sap. A further consequence of this picture of the internal structure of these 'crystals' is that their formation furnishes even less evidence than is provided by ordinary crystallization as to the homogeneity of the material.

Further light on the structure of the protein may be given by comparative study of similar materials. We have so far examined three strains of tobacco virus: mosaic, enation and aucuba, as well as two varieties of cucumber virus prepared by Bawden and Pirie[4]. The intramolecular patterns resemble one another very closely, but interesting and significant differences appear in the intermolecular patterns. All three varieties of tobacco virus show the same intermolecular distance in dry gels prepared in the same way, but show consistent differences of relative intensity of the different lines (see Table). The cucumber virus protein shows even more marked intensity differences and also a different intermolecular distance, 146 A., 4 per cent smaller than that of tobacco virus. There was no marked difference in spacing between the two cucumber strains.

The significance of these observations is that all the protein molecules have substantially the same general shape and size and are made of similar sub-units, but that these are arranged somewhat differently in the various tobacco virus strains and more markedly so in the cucumber virus. These results indicate the possibility of deriving a system of classification of viruses on the basis of their X-ray patterns.

Acquired Immunity against the 'Y' Potato Virus

Two years ago, thanks to Messrs. Sutton and Sons, Ltd., I obtained a couple of plants of *Schizanthus retusus*. At the base of each grew a mass of axillary shoots, forming a sort of 'witch's broom'. The plants were otherwise healthy, vigorous and in full bloom.

Sap inoculations were made from these axillary shoots to young schizanthus plants, tobaccos, and daturas, as well as grafts to older schizanthus plants. The daturas remained unaffected; the tobaccos developed a dull vein clearing, followed by a faint mottle and a weakly-developed vein-banding on the older leaves, all characters of Kenneth Smith's 'Y' virus in a weakened form. Such a variant I had long sought as a basis for protective inoculation of the potato. *Passage* through schizanthus induced a further weakening of the virus, as judged by its reaction on tobacco, in such manner that if the normal reaction were valued at 10, the weaker might be assessed so low as 3, though it was more often recorded as between 4 and 6. It was shown[1] that this new strain protected tobaccos against further infection with the normal 'Y' virus.

As the new strain of the virus was insufficiently attenuated to serve as a protective inoculation for potatoes, further attempts at reduction were made. Root fibres of tobacco plants, infected with the weak and strong forms of 'Y' respectively, were set up under sterile conditions in Erlenmeyer flasks, containing nutrient fluid, and incubated at room temperature, 22° C., 35° C., and 40° C. After about a week the virus extracted from the cultures was generally reduced, and it made little difference whether the cultured root had come from a plant infected with the common or the weak strain of 'Y', nor did the temperature greatly affect the process, though on the whole the best results were obtained at the higher ones. Nearly a hundred such strains have been obtained, most of which, when compared on tobaccos with the full 'Y', were valued at figures so low as 1 and 0·5; they have remained unaltered for three months.

In every single case it has been shown that the weak form affords complete protection against later inoculation with the normal 'Y' in tobacco. In the potato, variety "President" and "Up-to-Date", the weak strains produce a much reduced reaction—a mottle in the upper leaves, and in some cases a few fine streaks of necrosis on the under surface of some of the veins, whilst two or three lower leaves may drop. Second year symptoms in the glasshouse may be so slight as almost to escape observation. It has not been sufficiently established as yet, though it appears most probable, that the weak form protects in the potato, as in the tobacco, against subsequent infection with the strong virus.

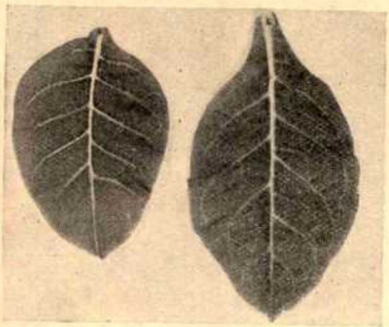

Fig. 1.

LEAVES FROM TOBACCO PLANT OF SAME AGE AND SIZE, AT THE VEIN-CLEARING STAGE; INOCULATED WITH THE COMMON 'Y' VIRUS (LEFT); A MUTANT FORM (RIGHT).

The possibility of inducing an immunity against one of the most destructive viruses met with in the potato field, is thus brought appreciably nearer.

Köhler[2,3] described what he thought to be weak forms of 'Y', but found that they did not protect against the common 'Y'. They were in fact infectious with the 'A' virus. In a communication just received[4] he reports that he has found a form of 'Y' which does protect; it is obvious from its reaction on tobacco, that it is of considerably higher virulence than the strains described above.

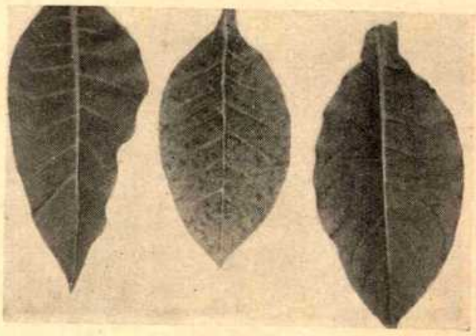

Fig. 2.

LEAVES FROM TOBACCO PLANTS OF SAME AGE AND SIZE, AT THE VEIN-BANDING STAGE; UNINOCULATED (LEFT); INFECTED WITH THE COMMON 'Y' VIRUS (CENTRE); AND A MUTANT FORM (RIGHT).

It should be stated that the weak 'Y' virus here described was not responsible for the 'witch's broom'.

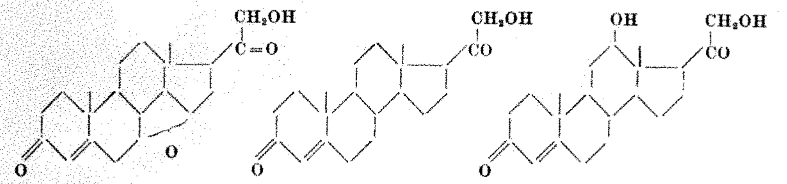
Partial Synthesis of a Crystallized Compound with the Biological Activity of the Adrenal-cortical Hormone

IN a letter to NATURE, Laqueur, Reichstein *et al.*[1] reported the isolation of a new crystallized compound in pure form which they named corticosterone (m.p. 180°–182° corr.) and which possesses the biological activity of the adrenal cortical hormone.

The empirical formula of corticosterone is $C_{21}H_{28-30}O_4$ and the structure which suggested itself is given in formula (I)[2]. This structure is chiefly based upon analogy with five pure compounds of the C_{21}-O_5-series (*A*, *C*, *D*, *E* and *Fa*) isolated from adrenals, the structures of which were definitely proved by degradations which furnished androstane as an end product. Only the function and position of one oxygen was left open. In consideration of the fact that corticosterone has a reducing group, gives the cholestenone band ultra-violet absorption spectrum and by chromic acid oxidation yields not a ketone of the C_{19}-series like the above mentioned compounds but an acid with 20 carbon atoms, no other formula was possible if the analogy were to be maintained. Function and position of the last (inert) oxygen is again left open.

Meanwhile, it seemed of more practical interest to check this assumption by synthetic models rather than by degradation experiments. Starting with stigmasterol and following a series of degradations and synthetic reactions, 21-oxy-progesterone (II) was prepared. The details will be given later. If formula (I) is correct, this compound differs from corticosterone only by the absence of the fourth oxygen, and can therefore also be called 'desox-corticosterone'. It shows striking resemblance with corticosterone. Its reducing capacity and the cholestenone-like ultraviolet absorption spectrum are in accordance with the function of the three oxygen atoms. But the chief point is that it has definite cortical hormone activity on adrenalectomized dogs and rats as shown by Prof. E. Laqueur in Amsterdam*. The minimal necessary daily dose is not yet exactly established, but it is certain that the activity is not less than one third of that of corticosterone. The crystals have m.p. 136°–138°, which possibly may be raised a few degrees when greater amounts are prepared. The important fact, however, is that this compound represents the first substance with high cortical hormone activity prepared from inactive material.



(I) (II) (III)

In a paper which arrived here a few days ago, Kendall *et al.*[3] state that corticosterone is identical with their compound *B* [4]. They now give the m.p. of the latter as 177°–179° (uncorr.) which is in excellent agreement with our value for corticosterone. Also the biological activity is quite of the same order as that reported by us. Kendall states that this substance has a higher cortical hormone activity than that of any other pure compound so far isolated. The empirical composition is given as $C_{21}H_{30}O_4$ and the structure is expressed in formula (III). While Kendall is thus the first to have published an appropriate structure for corticosterone, it must be pointed out that in his original paper[4], Kendall stated that compound *B* had a melting point 135°–139°, which is more than 40° lower than that now given, and an empirical composition of $C_{24}H_{34}O_5$. Nothing was said of its biological activity, while activity for compound *E* was claimed[5]. It is therefore scarcely possible that his original compound *B* is identical with corticosterone; it may have been a mixture.

On the other hand, we agree with Kendall, that his new results bring considerable evidence for his suggestion that the unknown fourth oxygen is contained in a secondary hydroxy group. If this suggestion can be proved conclusively, there will remain very few positions in which this hydroxy group can be placed. In the meantime, there exists evidence which would suggest its presence at position 11, rather than at position 12.

Variation of Wind with Height

IN the Professional Note of the Meteorological Office, Air Ministry, referred to in NATURE of April 24 in a Research Item (p. 721) on the "Variation of Wind with Height" at Wadi Halfa, Mr. J. Durward remarks upon an apparent discrepancy of nearly 70° between observation and theory when the results of observations of the winds by means of pilot balloons between 10,000 ft. and 13,000 ft. are compared with the run of the isobars at 4,000 metres as shown on Teisserenc de Bort's map.

I should like to remark that the discrepancy really emphasizes the necessity for further investigation of the meteorology of the equatorial region. Our general ideas of the relation of wind to the distribution of pressure, initiated by Buys Ballot's law, are based on the experience of temperate latitudes. As the equator is approached, the term in the equation depending on the earth's rotation gradually loses its significance and at the equator itself is altogether inoperative. In that region, if air 'comes to rest', it is by, somehow, acquiring a velocity of 1,000 miles an hour in order to keep pace with the ground on which it 'rests', a velocity which in temperate or arctic latitudes would be intolerable.

The equatorial region, therefore, cannot be regarded as amenable to the ideas of the relation of air-motion to the gradient of pressure which are illustrated by our weather-maps. Special investigation is needed to put the meteorologists of the equatorial zone in a corresponding position of advantage.

Special maps are certainly required; but what form the maps should take also requires consideration. Monthly means are not likely to be of much service where the geostrophic effect is negligible. Years ago, Mr. Lempfert and I got a good deal of insight into the working of that effect in the temperate zone by the construction of hourly maps compiled from the available records, and now that records of pressure are required for other purposes besides weather-maps, I have been wondering whether there are enough records in existence of pressure over land and sea to make hourly maps of the equatorial regions, if the records for a single week, for example, could be collected. The demonstration of the diurnal variation of pressure might be a test of the reality of the representation, and incidentally the local divergencies from the smooth curve would no doubt be expressed as weather. I have already an offer from Colombo of any information that is available there, and with the aid of ships and sealing-wax the walrus's idea of talking about many things might be realized!

Aldehyde Mutase

WITH reference to the note by M. Dixon and C. Lutwak-Mann, published in NATURE of March 27, p. 548, on the non-identity of aldehyde mutase with the aldehyde oxidase, I would point out that this fact was first established so far back as 1931 by Michlin and Severin and published in *Biochemische*

Zeitschrift, **237**, 339 (1931) under the title "Über die Nichtidentität der pflanzlichen Aldehydrase und Mutase".

We used the enzyme preparations of peas and potatoes. No traces of mutase was to be discovered in the purified preparations of potato-aldehydrase.

D. MICHLIN.

Biochemical Institute,
Academy of Sciences,
Moscow.
April 15.

WE cannot admit Dr. Michlin's claim to have been the first to show the non-identity of aldehyde mutase with aldehyde oxidase. It is well known from the work of Bernheim and others that the aldehydrase of the potato is a completely different enzyme from the aldehyde oxidase of animal tissues and milk (Schardinger enzyme). The fact that the potato aldehydrase has no mutase activity obviously does not show that the mutase and the Schardinger oxidase are distinct enzymes. Dr. Michlin indeed says in the paper referred to: "It has not yet been possible, as far as we know, to separate the mutase from the aldehydrase or Schardinger enzyme, either in milk or in animal tissues or yeasts. Wieland's supposition, based on kinetic considerations, that the mutase and aldehydrase of milk are identical, has once again been established by Wieland and Macrae." Dr. Michlin himself therefore evidently accepted the identification of the mutase with the Schardinger aldehyde oxidase. We have now separated these two enzymes and proved their non-identity.

Two-Dimensional Crystals of Silicon Pentoxide (Si_2O_5)

IT has been shown recently by me that vitreous silica and pumice, which have been considered up to the present as non-crystalline bodies, yield electron diagrams with surprisingly well-defined rings[1].

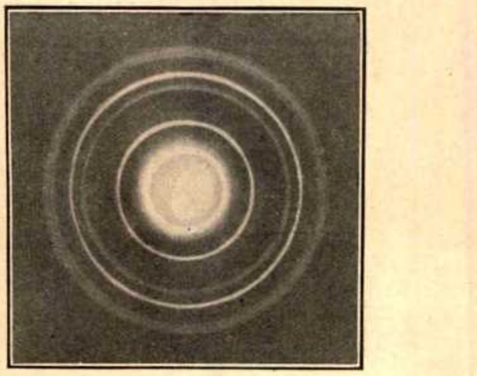

Fig. 1.

Further experiments, which were carried out last year in the Cement Institute, have shown that many other pozzolanic materials yield the same diffraction patterns, the only difference being that the latter did not contain certain rings, which were observed with vitreous silica and pumice. The most striking observation was that exactly the same diffraction pattern was given by every clay, in spite of the low order of symmetry of clay minerals. Such a typical diagram without 'extra' rings is shown in Fig. 1. The following table shows the corresponding Bragg spacings which were found from electron diagrams of some clays and pozzolanes with added pure sodium chloride as a standard substance ($a = 5 \cdot 626$ A.).

Intensities	d	a	hkl
20	4·450	5·138	(100)
15	2·561	5·122	(110)
0·5	2·235	5·162	(200)
5	1·688	5·157	(210)
9	1·491	5·165	(300)
3	1·291	5·164	(220)
3	1·240	5·162	(310)
1	1·120	5·173	(400)
0·5	1·028	5·174	(320)
0·5	0·974	5·154	(410)
0·5	0·895	5·167	(500)
0·25	0·858	5·148	(330)
0·25	0·842	5·145	(420)
Traces	0·808	5·195	(510)
,,	0·720	5·195	(520)

It follows from this table that the constant a, which was found by assuming that the lattice is hexagonal, is closely the same for all reflections and that the third index is zero throughout. This last condition indicates that the crystals in question are two-dimensional. The fact that such reflections are all observed also in the case of pure silica glass, suggests that the crystals are constituted only of silica. It follows from this that the bonds between tetrahedra of SiO_4 are here the same as in silicates of mica type and clay minerals, that is, the crystals have the form of endless firm sheets of composition Si_2O_5. This is confirmed by the close agreement of their parameters taken in orthohexagonal co-ordinates: $a = 5 \cdot 161$ A. and $b = a\sqrt{3} = 8 \cdot 939$ A. with that of some micas and clay minerals. We have, thus, for muscovite, $a = 5 \cdot 17$ A. and $b = 8 \cdot 94$ A.; for kaolinite $a = 5 \cdot 14$ A. and $b = 8 \cdot 90$ A.; and for metahalloysite $a = 5 \cdot 15$ A. and $b = 8 \cdot 90$ A.

The presence of only a few prominent rings in the case of clay minerals, instead of many weak reflections expected by reason of their low symmetry, is readily explained if one remembers that they are unstable at temperatures of 400°–500° C. The effect of cathode rays, which are, of course, partly absorbed by the specimen, would be similar. As to alumina, which is set free at such decomposition, it is probable that it is amorphous, and its influence on the diffraction pattern from Si_2O_5 crystals is as negligible as is that of a celluloid film.

The full account of this work will be published elsewhere.

Abnormally High Magnetic Permeability of Nickel Wire obtained by Surface Treatment

A LENGTH of 0·125 in. diameter pure nickel wire was heated to a temperature of 1,150° C. in a steady stream of hydrogen gas by means of an electric resistance furnace, and the maximum value of the permeability was measured periodically when cold. The results so obtained are plotted as Curve I in Fig. 1. It will be seen that the maximum permeability attains a value of 2,100 after about 7 hours. The greatest value for the permeability of nickel previously recorded[1] is 1,400.

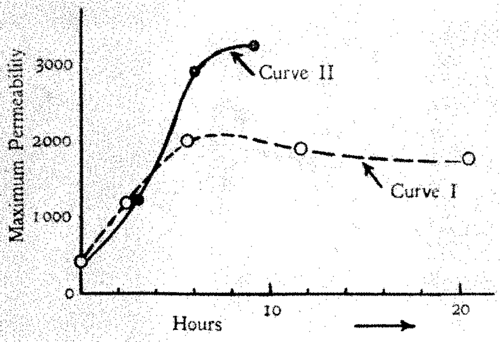

Fig. 1.

A length of nickel wire from the same coil was then electro-plated with copper to a thickness of about 0·003 in. and heated to a temperature of 1,030° C. in a steady stream of hydrogen, and the value of the maximum permeability was again measured at intervals when cold. The results are given in Curve II, Fig. 1. It will be seen that the maximum permeability now reaches the value 3,250. The value of the coercive force when the wire was demagnetized from an induction density of 5,150 gauss was found to be 0·24 oersted and the remanent induction density was 1,270 gauss.

The investigations are being extended to examine the effects of thin coatings of other metals such as aluminium, iron, cobalt.

Rotational Analysis of the '$3A$' Bands of CO

THE so-called '$3A$' bands of CO in the region 2200–2600 A. have been excited with high intensity in a discharge through neon in a Geissler tube with carbon electrodes, and the (0,1), (0,2) and (0,3) bands at 2389, 2489 and 2596 A. have been photographed in the first order of a large 'Hochheimized' concave grating (dispersion 1·3 A./mm.). By fine-structure analysis twelve branches have been detected in each band, the others being weak and overlapped. Of these twelve branches, six form heads, namely, O_3, O_2, P_3, P_2, P_1, Q_1 in order of diminishing wavelengths, and six do not form heads, namely, R_3, R_2, R_1, Q_3, Q_2, S_1. This shows the upper state to be a $^3\Sigma$ state, the rotational constant of which is found to be 1·9563 cm.$^{-1}$ from the average of three times six double combinations for the upper state.

The lines of the (0,1) '$3A$' band extend to the red-degraded (9,18) Fourth Positive band, the upper state for which predissociates[1] at 9·57 V. above the ground state of CO. The rotational analysis of the '$3A$' bands shows that the apparent increases of intensity of some of the Fourth Positive band lines (shown in plate I of the paper cited) behind the point of predissociation are caused by the superposition of certain '$3A$' band lines.

Structure of $BrSiCl_3$ studied by means of Electron Diffraction

USING a de Laszlo apparatus similar to that used for the study of $HSiCl_3$[1] and $HSiBr_3$[2], we have been able to measure the distances between the atoms of $BrSiCl_3$. These appear to be: Br-Cl = 3·41 ± 0·03 A.; Cl-Cl = 3·39 ± 0·01 A.; Si-Cl = 2·05 ± 0·05 A.; Br-Si = 2·19 ± 0·05 A.

In our work on $HSiBr_3$[2], we mentioned that the accuracy of the distance measurements of atoms in a molecule of this kind is very different for the different atoms involved. The distances between the halogens may be considered as measured with considerable accuracy, but on the other hand the distance between the halogens and the silicon atom is not so accurate. This is due to the fact that small variations of the Cl-Cl or Br-Cl distances affect greatly the positions of the different maxima of the curve giving relative intensity as a function of half diffraction angle; variations of Si-Cl and Si-Br distances have very little effect on this angle.

At the end of our earlier letter, "Geometrical Constitution of Silicichloroform"[1], we gave the following dimensions for angle and height of the pyramid $SiCl_3$: height, 0·65 A.; angle, 113° 30′. These should read: height, 0·62 ± 0·20 A.; angle, 111° ± 4°; as can be calculated from the distances Si-Cl and Cl-Cl given in that letter.

Fire-Walking

I SHALL be glad to be permitted to supplement the report in NATURE of April 17 on the fire-walking experiments which I organized for the University of London Council for Psychical Investigation. The article records the results of two tests (at Carshalton, on April 7 and 9), but does not mention the third—and final—demonstration with the Indian professional.

This was staged in the grounds of Alexandra Palace on April 20. The trench was 12 ft. long, 4 ft. wide, and 9 in. deep. Some four tons of oak logs were used in preparing the fire. At the time of 'walking', the surface temperature (measured by a representative of the Cambridge Instrument Co., Ltd.) was 800° C. This high temperature (the hottest fire we have managed to produce at any test) was due to the exposed position of the trench, and to the fact that a stiff breeze was blowing.

The first to walk was Ahmed Hussain (weighing 126 pounds), who took four steps in 1·6 sec. His feet were uninjured. Then Mr. Reginald Adcock (weighing 160 pounds), a young Cambridge graduate, walked the trench in 1·8 sec., taking three steps. His feet were not blistered or injured in any way. This was the third occasion on which he has done the fire-walk for us. Both walkers started off with the right foot. The slow-motion film I took of the demonstrators reveals no apparent superiority in walking technique on the part of the professional.

In the report in NATURE of our last fire-walking experiments, it is stated that "two steps with the same foot could only be done without injury by the practised professional". But Mr. Adcock demonstrated to us at Alexandra Palace that he, too, can take two steps with the same foot on a very hot fire without the slightest injury. Although he took three steps against the Indian's four, the time taken was 0·2 sec. longer; and the Englishman weighed 34 pounds more than the Indian. The times were taken by Dr. E. J. Dingwall, and Prof. J. C. Flugel, and I washed and examined the feet of the walkers both before and after the walks.

It is interesting to compare Mr. Adcock's feat with that of Kuda Bux's when the latter gave us his performance at Carshalton on September 17, 1935[1]. Bux walked on a trench 11 ft. long, with a surface temperature of 430° C. He weighed 120 pounds. Each foot was in contact with the embers twice. Adcock's performance surpassed that of the Indian's because the surface of the fire was nearly twice as hot, he walked farther, and the Englishman weighed 40 pounds more—the extra weight being a great disadvantage in fire-walking.

Instructional Tours for Students of Forestry

THE review of the future policy of the Imperial Forestry Institute in NATURE of May 1 contains a criticism of the proposal to replace tours of instruction in Germany, France and Switzerland by tours in the Scandinavian countries where forestry has not reached such an advanced or specialized stage. It is pointed out that whereas students in British forestry schools probably receive sufficient grounding in European forestry, those officers whose training has been outside Europe should be given an opportunity of seeing the best examples of organized forestry in countries like Germany, France and Switzerland, where the ecological, economic and sociological foundations have been most fully worked out.

On this point everyone who has kept in close touch with the developments of European forestry in recent times will, I think, be in agreement with the writer. Broadly speaking, it is possible to divide practical instruction in Continental forestry into two parts; (1) the essential grounding in well-established systems, to be obtained in France, Germany and certain other countries, (2) 'extension tours' to countries where forestry is in a less advanced stage. Without a good grounding in the methods covered by (1), extension tours must lose much of their value, and this would apply to the projected tour in Finland, however interesting and instructive it may prove to be on its own account.

In effect, the future policy of the Institute aims at substituting tours of the second category for those of the first, and the fear expressed in the article in NATURE that this may prejudice the chances of giving the essential grounding referred to above to those who have not already received it, is a very natural one. Fortunately, the machinery exists for meeting this difficulty. A good grounding in the fundamental principles of Continental forestry has always been a tradition of the Oxford School of Forestry, and, in order that these principles may be demonstrated on the spot, annual instructional tours have been organized by the School for many years past in France, Switzerland, Germany and occasionally in Austria and Czechoslovakia. Apart from undergraduate members of the School, it has been the regular custom in the past to include on these tours forest officers on leave and others who may wish to take advantage of them. Similar facilities will continue to be afforded in the future, and it is hoped, therefore, that the new policy of the Imperial Forestry Institute will in no way prevent those who desire to do so from obtaining a grounding in, or refreshing their knowledge of, the essential principles of European forestry.

The principal reason for selecting France, Switzerland and Germany for these School tours is that there is probably no region in the world, of similar size, which can show so great a variety of conditions, ideas and methods, whether from the point of view of administration and policy, economic conditions, sylviculture and forest management, extraction and utilization of timber, or any other branch of forestry. Practically all the standardized sylvicultural systems are to be seen, with various modifications to suit different species and conditions. These systems have formed the basis of scientific forestry in India, and their application is being extended to other parts of the Empire; it is therefore important that those entrusted with the management of our vast forest estate should be well grounded in the fundamentals of the subject.

R. S. TROUP.

School of Forestry,
Oxford.
May 3.

THOUGH the study tours of the Oxford Forestry School, and perhaps also those of other schools, offer opportunities to forest officers who have had their training outside Europe to obtain a first-hand acquaintance with some of the standard systems of forestry in France, Germany and Switzerland, the fact remains that the officers in question have to go outside the Institute for these facilities. The disturbing thing is that there is nothing in the declared policy of the Institute to encourage them to do so; rather are such tours criticized on the ground that "the highly specialized forms of forestry seen have little application to average conditions overseas". Prof. Troup says "it is hoped . . . that the new policy of the Imperial Forestry Institute will in no way prevent those who may desire to do so from obtaining a grounding in, or refreshing their knowledge of, the essential principles of European forestry". It is felt that this is not sufficient and that something more positive is required. It was because of the fear that the value of a sound training in European forestry as an equipment for tackling the special forestry problems of the various parts of the Empire is being minimized, that adverse comment was passed upon the policy of the Institute in this particular.

THE WRITER OF THE ARTICLE.

The University of Göttingen

MAY an English university teacher, who is at present enjoying the hospitality of a scientific institute in Göttingen, protest against the article in NATURE of April 24? It is undeniable that the University of Göttingen has suffered serious losses under the Nazi regime, and many features of the present university administration are entirely deplorable. On the other hand, there still remain in Gottingen men of considerable distinction (to mention only four outstanding names: Eucken, physical chemist; Windaus, organic chemist and Nobel prizeman; Prandtl, hydrodynamics; Rein, physiologist), who are continuing in the face of difficulties to maintain a high standard of scientific research and teaching. They are in no way responsible for the present administration; the statement that "Gottingen ceased in 1933 to be a scientific centre" is an unjustified insult and a discouragement which they feel most bitterly. The removal of the Jews from German universities, much as we may deplore it, is now complete and irrevocable. We have already indicated our disapproval with more than sufficient force, and a continuation of the campaign of abuse and boycott serves no conceivable purpose except to irritate the extremists to still further excesses and hurt the feelings of those moderates whose efforts to maintain the standard of academic learning need and deserve all the encouragement we can give.

"Any stick will do to beat a dog with." The anti-Semitic and anti-Catholic literature in circulation here illustrates how pathetically easy it is to make up a plausible case from odd statistics and excerpts, and it is regrettable that English attacks on Germany are beginning to show signs of the same fanaticism and lack of taste. Your anonymous correspondent is perhaps unaware that the speech which he quotes resulted in disciplinary measures being taken by the ministry of Education against Dr. Kahrstedt. The quotation about duelling is scarcely even relevant to the point at issue: an equally distorted view of English academic learning would be gained by a foreigner reading our Press at the time of the Oxford and Cambridge Boat Race. My present colleagues, mostly appointed since 1933, are men of high scientific ability in spite of the "complex apparatus" which apparently should have "prevented them from joining the junior teaching staff", and we do not find ourselves in any way hindered or disturbed in scientific work. Is it too late to make a plea to English universities and periodicals for that dignified tolerance and restraint which we like to regard as a national virtue and which is the only effective counter to political hysteria? Nothing will be gained and much lost by cutting off all contact with an academic society which, in spite of all that can be justly said against it, is still producing, and will continue to produce, positive scientific work of real value.

J. D. LAMBERT.
(Lecturer of Trinity College, Oxford.)

Physikalisch-chemisches Institut,
Gottingen.
May 10.

MR. LAMBERT points out, what has never been doubted, that there are distinguished men of science at Gottingen who are not responsible for the present administration. It cannot be to their advantage that representatives from English universities should fraternize with precisely those officials who are most closely associated with the features which he tells us that he (and implies that his German friends) most deplore.

The figures quoted in the article on Gottingen are not "odd statistics and excerpts"; they are figures carefully gathered by competent, trained and impartial observers who have spent several months on this particular task. The inquiry shows that the careers of approximately one fifth of the scholars and men of science in Germany have been ruined and the scientific opportunities and intellectual integrity of the remaining four fifths have been gravely injured. It must take generations for the profession of learning in Germany to recover the dignity and esteem which it has lost.

The Minister of Education, Herr Rust, has spoken in terms as extreme as Dr. Kahrstedt, so that the disciplinary measures to which Mr. Lambert refers can be intended only for external consumption. Mr. Lambert should read the address given by Herr Rust at the "jubilee" of the University of Heidelberg last year.

Mr. Lambert and certain of his colleagues "do not find themselves disturbed . . . in scientific work". Others are less fortunate. Dismissals continue, and at Gottingen itself a professor of long service and high standing was dismissed a few days before Mr. Lambert wrote.

Mr. Lambert makes no mention of the choice of June 30 for the celebrations both at Heidelberg and Göttingen, or of the association of that day, in every German mind, with the greatest political massacre of modern times. He does not mention the entire failure of the appearance of any *Göttinger Sieben* to protest against the assaults on learning and liberty. He does not mention that more than a fifth of the staff of the University was dismissed with scarcely a word of protest or sympathy.

The difficulty of recruiting staffs for the German universities is as well known in Germany as in England. A special decree was recently issued by the Ministry of Education, and circulated in a confidential leaflet to university teachers expressly forbidding public discussion of this subject.

Mr. Lambert states that "the quotation about duelling is scarcely even relevant to the point at issue". If duelling be compulsory in the German universities, it must effect the recruitment of the staff in very many ways. To mention one only, it must exclude practising Catholics, to whom duelling is forbidden. Nearly one third of the population of Germany is Catholic.

THE WRITER OF THE ARTICLE.

Boltzmann's *H*-Theorem

WHEN Boltzmann first published the celebrated theorem now generally known as the *H*-theorem, he used the symbol *E* (presumably as the first letter of *entropy*), not *H*. It has been suggested that when *H* was first used for this theorem it was intended to be the capital Greek letter *eta*: but the first paper known to me in which *H* is used for Boltzmann's entropy function is one by Burbury[1], who seems to have changed Boltzmann's symbol *E* to *H* for no special reason; later Burbury used *B* for an almost identical function, which he called Boltzmann's minimum function[2]. Boltzmann himself wrote *E* so late as 1893[3], but in 1895[4] he used the letter *H*. This use of *H* must have seemed mysterious to many generations of students, and it would be interesting to know whether any reader can account for its use or give an earlier instance of it.

S. CHAPMAN.

Imperial College,
South Kensington.

Points from Foregoing Letters

FROM mass-spectrographic measurements of several doublets (atoms and groups of atoms having the same mass/charge ratio), Dr. F. W. Aston has deduced with a greater degree of accuracy the 'packing fractions' and isotopic weights of the atoms of carbon, ^{12}C, oxygen, ^{16}O, and argon, ^{36}A.

The absorption by silver of 'thermal neutrons' (which at a given temperature have energy corresponding to that of thermal agitation of atoms in the surrounding medium) has been determined by Drs. O. R. Frisch, H. von Halban, jun. and Jorgen Koch at several temperatures up to 415°. The authors point out that there is a discrepancy between the observed values and those deduced on the assumption that the absorption is inversely proportional to the velocity of the neutrons. This discrepancy, they consider, may be due to the inhomogeneity of the thermal neutrons, due on one hand to the presence of a certain number with energy greater than the thermal range, and on the other hand to an excess of thermal neutrons of energy less than 0·1 eV.

Drs. J. D. Bernal and I. Fankuchen submit diagrams indicating the structure of the so-called crystalline virus protein prepared by the method of Stanley and Wyckoff. There is a two-dimensional hexagonal regularity at right angles to the long protein molecules, but none in the direction of their length. The molecule is made up of piles of submolecules of dimensions 20 A. × 20 A. × 20 A., somewhat smaller than the normal protein molecule. The structure of the 'crystals' is somewhat like that of the colloidal 'micro tactoids'. The authors also give a table of the inter-molecular distances in several tobacco and cucumber viruses, and suggest that viruses may eventually be classified on the basis of their X-ray patterns.

Methods of preparing an attenuated form of the 'Y' potato virus which affords complete protection to tobacco plants, and partial protection to potato plants against the more virulent form, are described by Dr. R. N. Salaman. To obtain this immunizing preparation, the virus is either passed through a schizanthus plant or is first inoculated into root fibres of tobacco plants, under controlled conditions.

The synthesis of a compound (21-oxy-progesterone) which has activity similar to that of the adrenal-cortical hormone (corticosterone) is announced by M. Steiger and Dr. T. Reichstein. This, the authors state, is the first instance of a substance with high biological activity (tested on dogs and mice from which the adrenal glands have been removed) and brings nearer the final elucidation of the molecular structure of corticosterone.

Sir Napier Shaw directs attention to the fact that our knowledge of the relation between wind and pressure distribution is based on experience in temperate latitudes and is not applicable to equatorial regions. He appeals for further data to enable meteorologists to deal with the latter conditions.

Two-dimensional crystallinity is deduced by N. A. Shishacow in the case of vitreous silica and pumice, from their electron-diffraction patterns, which show well-defined rings. The author gives a table of intensities and Bragg spacings, as deduced from the electron diagrams of some clays and pozzolanes.

When pure nickel wire of diameter $\frac{1}{8}$ in. has been plated with a thin skin of copper and heated to a temperature of 1,030° C. in hydrogen, Dr. T. F. Wall finds that a maximum permeability of 3,250 is attained. When demagnetized from an induction density of 5,150, the coercive force is 0·24 and the remanent induction density is 1,270.

The fine structure of the so-called '3*A*' bands of the carbon monoxide spectrum in the ultra-violet (2200–2600 A. region) obtained by means of a high-intensity discharge between carbon electrodes in neon gas is described by Dr. R. Schmid and Dr. L. Gerö.

The distances between various atoms in the molecule of bromsilicichloroform BrSiCl$_3$, as obtained by means of electron-diffraction measurements, are given by Prof. M. de Hemptinne and J. Wouters. From the nature of the experiments, the accuracy of the determinations is not the same for all atoms, being greater for the distances between chlorine and bromine than between these and silicon atoms.

Details of comparative experiments on fire-walking, under controlled conditions, carried out by an Indian professional and an English amateur are given by Harry Price. Neither suffered injury. Though the professional took four steps to the amateur's three, the slow motion film shows no superiority in walking technique on the part of the professional.

Prof. S. Chapman, referring to the use of the letter *H* by Burbury to designate, in 1890, Boltzmann's entropy function (for which Boltzmann himself had used the symbol *E*), inquires if any reader can account for the use of the letter *H* in this context at an earlier date.

Research Items

Anthropometry of Beaver and other Indians of Canada

In the third of a series of reports on the physical characters of Canadian Indians of Athapascan stock, Mr. J. C. Boileau Grant analyses observations of Beaver Indians made by himself in 1929, and compares them with measurements of Sekani and Carrier Indians made by Mr. Diamond Jenness in 1923 (*Nat. Mus. Canada, Bull.* 81, Anthrop. Series, 18). Out of 185 individuals measured by Mr. Grant only pure Beaver, 35 men and 13 women, are considered. The Sekani and Carrier number 35 men and 31 women. Taken as a whole in one group, these people are short in stature, broad-headed with very high cephalo-facial index, ranging by tribes from 96·2 to 98·4 for the men, and from 95·5 to 96·4 for the women. A notable feature is the high percentage of eyes of a lighter shade among the Carrier and Sekani Indians. The principal measurements and indices (men) are as follows: Beaver—stature, 168·3; cephalic index, 80·5; cephalo-facial index, 96·8; facial index, 82·9; nasal index, 70·6. Carrier and Sekani—stature, 169·7; cephalic index, 81·4; cephalo-facial index, 96·2; facial index, 84·5; nasal index, 70·5. Compared with measurements of Chippewayan, they show that the Chippewayan are shorter in stature, have a lower cephalic index, a longer head, and a greater cephalo-facial index. A further notable feature in the observations of the Beaver is the high percentage of the *A* group in the blood group observations, which is remarkable in view of the stress laid on their racial purity. Of forty observations, twenty-one were *O* and nineteen *A*, which is quite at variance with observations made among the Chippewayan in 1928 (80 per cent, 10 per cent, 10 per cent and 0 per cent), and observations by Ruggles Gates on the Mackenzie River (85 per cent, 15 per cent, 0 per cent and 0 per cent). The blood of sixty-one various other Indians and mixed breeds in the Peace River area, from which the Beaver were taken, showed a similar distribution to the Beaver. There is evidently an unusually high distribution of the *A* group in the Peace River area.

Influence of Recreation on Sedentary Workers

An interesting account is given in the January-February issue of the Polish journal, *Przeglad Fizjologii Ruchu* (Review of the Physiology of Movement), by Dr. W. Missiuro of an investigation on the effect of active recreation upon the output of female sedentary workers. These were between twenty-two and twenty-nine years of age, engaged (seated) in teams of eleven in making shoes. A daily ten minutes interval for physical exercise was introduced, and produced favourable results upon the health and the output of the workers. Dr. Missiuro made a comprehensive physiological study of the effect of this active recreation upon the individual's intake of oxygen and output of carbon dioxide, rise in energy consumption, pulse frequency, 'hæmoglobin value', urea, chloride and sugar content of blood and urine, etc. Among the results observed were a definite diminution of diuresis during work. No case of increase in acidity or albumen in urine was recorded. Perhaps the improvement was most marked in its psychological effects.

Studies of the Grasshopper's Egg

The formation of the membranes of the acridian (grasshopper) egg has been re-investigated by Eleanor H. Slifer (*Quart. J. Micro. Sci.*, 79. Pt. 3, March 1937, p. 493). She finds that in four species of different genera, the eggs possess a delicate vitelline membrane, as described by earlier, but overlooked by recent, investigators. In eggs of *Melanoplus differentialis*, the yellow cuticle is deposited by the serosa at 25° C. during the sixth and seventh days after laying. As soon as this layer is completed, the serosa begins to deposit a second layer, which is white, very tough, and though fibrous in appearance is chitinous in composition. So tough is this membrane that it would prove an obstacle to the emergence of the young grasshopper, but three days before hatching it begins to be dissolved by an enzyme, so that finally the merest trace of it remains. It has been supposed that this enzyme is secreted from the embryo's mouth, but Miss Slifer shows that this is not the case. She applied ligatures at various levels to a series of eggs due to hatch seven or eight days later, so as to isolate the digestive fluid in different regions, if present. The enzyme was finally located in the region of the pleuropodia (appendages of the first abdominal segment), and its formation by these structures was confirmed by removing them. After this operation, the white cuticle remained undissolved, and the embryos in the eggs, though working vigorously to free themselves, were unable to do so. The pleuropodia of *M. differentialis* are trilobed stalked bodies about ⅛ mm. in diameter, and are made up of a single layer of very large cells. Similar structures occur in other insects, and their function has long been a puzzle; possibly, it is the same as in the grasshopper.

Snakes of Maryland

The Natural History Society of Maryland is credited by the publication of a well-printed and illustrated pamphlet on the snakes of Maryland (pp. 103+10 plates) by Dr. Howard A. Kelly, A. W. Davis and H. C. Robertson (Baltimore: Natural History Society of Maryland). The Maryland snake fauna comprises 26 non-venomous and 2 venomous snakes, the copperhead and timber rattlesnake. The identification of the species is simplified by keys to the salient characters of adult and young individuals, by short descriptions of form, coloration and habits, and by excellent plates in colour and photographs. A general introduction and a chapter on the treatment of snake bites completes the work. One cannot but admire the presence of mind of the individual who, being breathed upon by the dreaded blowsnake (a harmless puff-adder), immediately "took a pint of whisky to quiet his heart, and couldn't work again for two years".

Mole Crickets and their Allies

The attention of students of insect morphology is directed to an elaborate paper by F. Carpentier on the structure of the thorax in mole crickets and their allies (*Mém. Mus. Roy. d'Hist. Nat. Belgique*, Fasc. 4; 1936). For a long time past, true mole crickets have been grouped with the series Gryllotalpides, while certain other forms or false 'mole crickets' constituted the Tridactylides. The author examines the detailed structure of the thorax, wings and legs and, on the basis of the morphological criteria thus afforded, assesses the mutual affinities of *Gryllotalpa*, *Tridactylus* and *Cylindroryctes*.

Care of Ornamental Trees

THE contribution which certain trees and shrubs can make to garden beauty is so great that the gardener naturally desires to prolong their good growth as much as possible. Mr. A. D. C. Le Sueur lectured to the Royal Horticultural Society in January of this year on "The Care of Ornamental Trees", and the text of his lecture appears in the Society's *Journal* of April (62, Pt. 4, 141–152). Many factors of disease, of damage by birds, and of the interaction of urban conditions, are discussed. The beech disease, caused by the insect *Cryptococcus fagi*, is deemed to be only a secondary infestation which masks some previous weakness of nutrition, or prior attack by a virulent fungus. Slimy fluxes from wounds of various trees sometimes prevent their healing, but a thick application of hot tar will provide effective treatment. The action of lightning, and damage by electrical transmission lines, may cause wounds upon desirable trees. It is interesting to find the statement that groups of trees may be killed as a result of electric discharge when the earth acts as a positive potential during thunderstorms. Poisoning of trees by coal gas escaping from defective mains, or by sewage leaking from pipes or cesspools, are two factors which may damage trees growing in an urban environment. The paper deals with the practical treatment of these, and other maladies which might diminish arboreal splendour.

Distribution of Destructive Earthquakes

IN the recent issue of the *Matériaux pour l'Étude des Calamités* (No. 37, 3; 1936), Ugo Vanni deals in great detail with the distribution of destructive earthquakes. His work is based on Milne's well-known catalogue and on its extension from 1900 to 1921. From the year 1850 onwards, he notices that Milne's catalogue becomes stable in the annual number of earthquakes, while, in the preceding half-century, the number gradually increases, the average annual numbers for the two half-centuries being 11·6 and 30·7. During the years 1850–99, Milne records 955 earthquakes of his intensity I, 366 of intensity II and 217 of intensity III. In considering the relative frequency of earthquakes in different countries, Vanni takes no account of their area. Including only shocks of the two higher degrees, he gives the following order: Philippines with 78 earthquakes, Asia Minor with 42, Italy 29 and Greece 26, while Chile occupies the eleventh place with 15, and New Zealand the thirty-fourth with 5. Or, again, dividing Milne's degree III into two grades and taking only those of the higher (corresponding to public catastrophes), he finds for the years 1850–1921 the following order: Asia Minor, China, Japan, Italy, with Chile in the eighth place and Greece in the eleventh. In the same issue of the *Materiaux* (p. 64), C. Bois continues his valuable catalogue of destructive earthquakes for the first half of 1936, during which the number fell so low as 12, including five in China and Japan, three in the Balkan peninsula and two in South America.

Correlation of Ozone with Atmospheric Phenomena

AT a meeting of the Royal Meteorological Society held on April 21, A. R. Meetham read a paper dealing with the upper atmosphere. The author described a statistical investigation that he had made with the view of finding an explanation of the observed connexion between the total amount of ozone in the atmosphere and various other geophysical phenomena, including the distribution of barometric pressure at sea-level—which last has for some time past been known to be correlated in some way with the total amount of ozone. The author obtained correlation coefficients between the daily values of the ozone, after these last had been corrected for their known annual variation (maximum in April), and a number of variables in the upper air such as the height of the tropopause and pressure and temperature at various points in the troposphere and the stratosphere. He found that the ozone was more closely connected with entropy and potential temperature in the stratosphere than with any other function of pressure and temperature, or with any other geophysical phenomenon yet investigated. The last part of his paper is occupied with a very speculative attempt to arrive at an explanation of the statistical results, and in it the author is obliged to assume that there is an appreciable amount of vertical circulation of the air in the stratosphere, notwithstanding the very stable distribution of temperature in that region, an assumption that will not readily be acceptable to meteorologists in general.

Photosensitized Reactions involving Deuterium

DURING the past two years, Prof. H. S. Taylor and his collaborators have studied the mercury photosensitized reactions between methane and deuterium, tetradeuteromethane (CD_4) and hydrogen, and methane and CD_4. Of the processes which occur, some yield deuteromethanes of varying deuterium content whilst others give condensation products of the hydrocarbon (*J. Chem. Phys.*, **5**, 212; 1937). The composition of the deuteromethanes in the reaction products is estimated quantitatively by comparing the relative intensity of absorption of a particular mixture at various characteristic wave-lengths in the infra-red with the values for 'standard' compounds of definite deuterium content (*ibid.*, **5**, 1; 1937). From a study of the influence of temperature and light intensity on the reaction, it has been shown that the reaction processes must be interpreted by a chain mechanism. The rates of exchange in the reactions CH_4+D_2 and CD_4+H_2 are practically identical and much more rapid than in the reaction CH_4+CD_4. The products of the condensation reactions are saturated hydrocarbons at all temperatures, except 490° C., where small traces of unsaturated hydrocarbons were identifiable. It was also found that methane condensed to a greater extent in the presence of deuterium than in the presence of hydrogen. Below 200° C., the recombination of methyl radicals and atomic deuterium, both produced in primary processes, probably predominates; at 200° C. there is mostly exchange between methyl radicals and deuterium molecules yielding CH_3D and D; whilst around 300° C. the exchange is effected most probably by $CH_4+D \rightarrow CH_3+HD$. The condensation process is thought to take place by recombination of alkyl radicals. On the basis of these processes, the experimental data have been satisfactorily interpreted.

The Museums of India*

THE report of the Museums Association on the museums and art galleries of India completes a series of reports, which not only comprises a full directory of the museums of the British Empire, but also contains critical commentaries on every phase of their activities. In the course of six or seven years, nearly two thousand museums in all parts of the Empire have been visited. The funds for this survey were provided by the generosity of the Carnegie Corporation of New York, excepting the grant for the British survey of 1926–27, for the expenses of which the Carnegie United Kingdom Trust was responsible.

The survey of the museums of India began in October 1935. It was carried out by Mr. S. F. Markham, M.P., Empire secretary of the Museums Association, and Mr. H. Hargreaves, formerly director-general of archæology in India. Personal visits were made to the greater number of the museums of India, and for purposes of comparison Ceylon, Malaya and the Dutch East Indies were visited. The funds, as already mentioned, were provided by the Carnegie Corporation of New York, to fill the gap in the Empire survey, but on the distinct understanding that assistance could not be provided for the Indian museums, such as had been made available for the museums of the Empire.

In a brief historical survey the report points out that the institution of museums in India began so long ago as 1796, when the Asiatic Society of Bengal decided that the many curiosities it had accumulated should be suitably housed in Calcutta. Donations were invited; but the plan proved premature, and it was not until 1814 that the Society was able to establish a proper museum. The scope of the museum was defined as "the illustration of Oriental manners and history and to elucidate the peculiarities of art and nature in the East". After persistent pressure, official financial assistance was received from the Court of Directors of the Honourable East India Company in 1839, a grant being made for the salary of a curator, and the Government of India was authorized to make grants for special purposes. Four years previously the Government itself, being anxious to develop the country's mineral resources, had decided to found a Museum of Economic Geology in Calcutta. This was opened in 1840. The Central Museum of Madras was opened in 1851 as the result of a decision of the East India Company, "impressed with the advantage of storing up in some one place the knowledge and the material which had been acquired by the investigators working in different parts of the Peninsula, and with the object of fostering scientific enquiries and pursuits". This was due to the activity of the Madras Literary Society, a branch of the Royal Asiatic Society, but the proposal was mooted so long before as 1819. By 1857 there were twelve museums in India. Further growth was checked by the Mutiny of 1857, and thereafter was slow until the jubilee of Queen Victoria in 1887. This was responsible for the foundation of a number of museums; and a further stimulus was provided, especially in the foundation of archæological museums, during the viceroyalty of Lord Curzon of Keddlestone, 1899–1907, whose personal interest and munificent benefactions did much to encourage study of Indian art and culture. The most recent development, commendable though not without its drawbacks, is the institution of museums on the sites of archæological excavation, in which the local finds are housed, while in some instances excavated buildings are preserved so far as possible intact.

It is, however, significant that notwithstanding activity since 1914, and especially in the last decade, a number of museums formerly in existence have closed, the most recent being Quetta, which has not been reopened since the earthquake of 1935. The Phayre Museum in Rangoon has been closed for thirty-three years, though the collections are reported to be still in existence.

There are now a hundred and five museums in India. These have a quadruple origin: first, the scientific museums at the great centres of government established by the Governments and their European servants; secondly, the museums established by the Indian States, which have followed this example; thirdly, the local museums established by the Archæological Survey; and fourthly, the museums created by the teaching institutions and learned societies for their own requirements. The great majority of the museums are under Government, municipal or provincial control. It is noted, however, that there are fifteen towns with populations of more than 100,000 which have no public museums. Nowhere, except in China, it is pointed out, are there so many large towns without a public museum. Burma, with a population of more than fourteen millions, has no Provincial Government museum which is now open. Yet 35,000 visitors annually pass through the small Palace Museum at Mandalay.

Neither in British India nor in the Indian States, the report points out, have museums been distributed in a rational manner—some of the smaller towns, such as Dehra Dun, have museums of which any great city could be proud, while populous centres, such as Ahmedabad or Amritsar, have no museum at all. There is not a single province or Indian State that does not compare poorly with the leading countries of Europe, the British Commonwealth or the United States. In fact, with the exception of the most backward countries of the world, there is not an area where museums count for so little, are so meagrely supported, or are so few and far between.

Finance repeats the same story in another idiom. The financial provision for the museums is absurdly inadequate. The total amount spent on the one hundred and five museums is no more than £58,000 per annum, and out of this the largest five museums have an income larger than the remaining hundred put together. The total amount, in fact, is less than is spent on a single great museum in the capital cities of Europe or America.

It is not difficult to diagnose the causes that lie at the root of most of the defects in the provision of museums in India. A general apathy and neglect, combined with and in part the cause of an inadequate provision of funds, is responsible for failures in maintenance, an insufficiently high standard in staffing, both as to numbers and qualification, and a lack of energy in administration, which has failed to keep abreast of museum development in other countries, while allowing exhibits to deteriorate and perish through neglect of proper care and attention. Unless immediate steps are taken, the report says, proof of India's cultural greatness in past time, of her technical and artistic skill in perishable materials, will vanish for ever from India itself and will only be found in the vast repositories of Europe and elsewhere.

---

* The Museums of India By S. F. Markham and H. Hargreaves. Pp. v+229+25 plates. (London: The Museums Association, 1936) 5s. net.

Notwithstanding the illiteracy of the population, generally estimated at ninety per cent, the inadequacy of the museum cannot be excused on the ground of the lack of interest of its public. It is stated that during a recent festival in Madras, no less than 130,000 individuals passed through the Museum in one day, while the Mysore Government Museum, Bangalore, has 260,000 visitors annually.

As is indicated by the directory of Indian museums, which forms Part 2 of the report, the character of the Indian collections on the whole is sufficiently varied. The predominant place is taken by exhibits illustrating the archæology, history and art of India whether in specialized institutions or as part of a larger institution. The variety and extent of the fauna of India are well shown in the famous collections of the Indian Museum, in the Prince of Wales Museum, Bombay, and the museums at Madras, Nagpur and Darjeeling. The Geological Survey has four galleries in the Indian Museum, which are fully representative of the geology of India. One deficiency to which attention is directed is the inadequacy of the ethnological collections illustrating the culture of the varied peoples of India, although the collections demonstrating the culture of the aboriginal tribes at Lucknow, Calcutta, Nagpur, Madras and Trivandrum are noted. The importance of agriculture and forestry in India is responsible for the efficiency of the Forest Research Institute at Dehra Dun, with its world-famed collections devoted to botany, sylviculture, entomology, timber and other forest products, while systematic botany is covered by the Herbarium of the Royal Botanic Gardens, Sibpur, where there are more than 2,000,000 specimens There are also agricultural museums at Coimbatore and Lyallpur. The Indianization of the staffs is now virtually complete.

Of the recommendations appended to the report, the most important is that the Government should appoint immediately an Inspector General of Museums with European experience, and an assistant to be trained overseas. Further, that the constitution of the Indian Museum should be reorganized to permit the appointment of a director with full powers and freed from other duties. In view of the criticisms of the standard of staffing and of the lack of general appreciation in museum administration of advance in technique and development of museums as centres of cultural organization, special emphasis should be laid on the recommendation that the Standing Committee on Museums and Museum Conferences should be revived, and funds provided to meet the cost of Committee, travelling allowances and printing; while the provinces and municipalities are advised to provide more funds for maintenance and also adequate and competent staffs.

The Service of Unified Knowledge

MR. H. G. WELLS'S recent discourse* on the disastrous inco-ordination and waste of modern knowledge and thought concluded with a warning that "without a World Encyclopædia to hold men's minds together in something like a common interpretation of reality, there is no hope whatever of anything but an accidental and transitory alleviation to any of our world's troubles".

To Mr. Wells's appeal to the learned world to set its house in order comes an answer from Prof. A. B. Dobrowolski, director of the Meteorological Service of Poland, president of the Warsaw Geophysical Society and professor of pedagogic sciences in the Free University of Warsaw. Prof. Dobrowolski, while recognizing the potential value of Mr. Wells's project, suggests that it does not go deep enough. If men's minds are to be held together in something like a common interpretation of reality, it is essential that they should have sufficient general culture for an insight into and appraisal of the rich and complicated life of the civilized world of to-day.

This means that there must be a revival of the ideal of a liberal education and efficacious means for realizing it at a level higher than that of the secondary school. A boy or girl leaves school with a certain capacity for self-education. This capacity ought to be cherished and utilized as a means towards higher general education; but encouragement and support are needed. Society ignores the need. The universities are concerned to form, not cultivated men and women, but specialists. Such general culture as is acquired after school-days are over is derived from no systematic cultivation of the arts of observing and thinking, with study to understand and appraise the observations and thoughts of others; but from a purely haphazard succession of experiences, chance readings, conversations, attendances at exhibitions, public meetings, concerts. So, in the vast majority of cases, the intellectual worker's conception of the civilized world, his philosophy of life, if such it may be called, which will determine his reactions to circumstances throughout his life, is the haphazard product of a series of accidents, a thing of shreds and patches.

Prof. Dobrowolski suggests that the remedy lies in creating, in every university, a new 'faculty of general knowledge', the function of which would be to arouse, especially among the young, a lively sense of the value of higher general culture and to stimulate and guide efforts to attain to it through self-education. The mere existence of such an institution would be, already, a most effective piece of propaganda. Among its activities would be, in addition to classes, discussions, exercises, seminars and individual counsel and advice; also publication of specially prepared handbooks for aspirants to self-culture, since the popular manuals now on the market do not meet the case.

---

* Delivered at the Royal Institution on November 20 and published as a Supplement to NATURE of November 28, 1936, under the title "The Idea of a World Encyclopaedia".

Prof. Dobrowolski has won for his ideas the support of a group of some fifteen of his colleagues, and a working model of the suggested university faculty has been brought into being under the significant name "Universitas Rediviva". For eight months, thirty students of varying ages and professions have taken part in this experiment. The work is organized in two stages: first, evening classes and exercises extending over four semesters (two years) and occupying eight hours a week; secondly, tutorial counsel given, orally or by correspondence, by various specialists, and group discussions.

The subject-matters of the course range over the widest fields: the art of thinking, general history of ideas, science and technology, art, literature, psychological sciences, economics and sociology, education, the use of leisure, ideologies and criteria of values. In practice, they are divided into six groups: (1) physics, chemistry and astronomy, with mathematics; (2) natural and geographical sciences; (3) psychological sciences; (4) social sciences; (5) pedagogic sciences, and, in relation thereto, the technique of intellectual work, conceptions of the world, philosophies, etc.; (6) art and literature.

Embracing, though it does, the whole of civilization, the programme is intended to be taken in its entirety by every student, and, in order to ensure unity of treatment the professors keep ever before themselves their common aim: the acquisition by the student of the capacity to judge, to appraise, to estimate.

Association of Teachers in Technical Institutions

THE twenty-eighth annual conference of the Association of Teachers in Technical Institutions was held in Coventry during Whitsuntide. On May 17, the president for 1937–38, Mr. W. E. Park, principal of the Technical School, Luton, was installed by Mr. W. T. Maccall, of Sunderland Technical College, who had filled the presidential office during 1936–37. A civic welcome to the Association was accorded by the Deputy Mayor of Coventry, the chairman of the Education Committee and the chairman of the Technical Schools Sub-Committee of Coventry.

"In no town more than Coventry," said Mr. Park in his presidential address, "can we see so well exemplified the changes which are so rapidly taking place. Its industries, built up on the tradition of skilled craftsmanship, are being adapted to the means of the defence of our realm, and as the adaptation proceeds the serious shortage of skilled workers and trained technicians is being realized". It is the business of technical educationists to solve such problems as these, Mr Park continued. But it must be remembered that, whatever the needs of the immediate present, the fundamental business of technical education is to serve the industrial and commercial civilization which is ours. To that end, the system must be carefully and scientifically planned. For this reason, he emphasized the value of a report on "Co-operation in Technical Education" recently prepared by a conference of representatives of the associations of local education authorities and the London County Council and issued by the Board of Education. Mr. Park directed special attention to the passages of that report which recommended consultation between authorities in regard to the provision and planning of new buildings, and the need for co-operation in connexion with the distribution and delimitation of different stages or types of instruction. Association between authorities to deal with problems of industrial regions as a whole facilitates negotiations with industrial and commercial organizations for the region, and will enable possibilities in connexion with the utilization of teachers, particularly with those possessing high qualifications of a specialized character, to be examined much more carefully than has hitherto been the case.

Mr. Park insisted that technical education will fail its ultimate purpose if it neglects training for citizenship. Merely to train technicians either for the purposes of re-armament or for the bare needs of industry and commerce would lead to the creation of a nation of robots. Hence the Association's activity in conjunction with its sister associations in producing a "Report on Education for Citizenship" which was discussed and accepted during the Conference. Whether 'citizenship' be taught directly or indirectly in technical colleges, the question of "bringing politics into the college" must be faced. It is important in this connexion to remember three things: First, that in the initial stages the social sciences are mainly descriptive and non-controversial; second, that the average teacher is conscientious and knows that he can and must distinguish between facts and his own opinions; and third, that if a scientific approach to social and political problems is not taught in the class room, young people will be left completely unprotected against propaganda in later life

Among the resolutions passed by the Conference was one which urged the release of technical teachers, after seven years' teaching service, for further periods of industrial service without loss of salary or superannuation rights. Another resolution urged the advisability of increasing facilities for the attendance of young persons at part-time day technical classes in preference to evening classes. This arrangement the Conference held to be in the best interests of students, physically and mentally, and ultimately to be most beneficial to the nation and to industry. In a resolution dealing with the Factory Act, the Conference expressed the view that no overtime should be worked by young persons less than eighteen years of age.

Science News a Century Ago

General Registration of Diseases

IN connexion with the Act for registering births, deaths and marriages in England, the issues of the *Lancet* and *London Medical Gazette* of May 27, 1837, contained the following letter signed by Henry Halford, Astley Cooper and J. Hingston: "We, the undersigned, President of the Royal College of Physicians, President of the Royal College of Surgeons and Master of the Worshipful Society of Apothecaries, having authority from the several bodies whom we represent, do resolve to fulfil the intentions of the legislature in procuring a better registration of the causes of death, being convinced that such an improved report cannot fail to lead to a more accurate statistical account of the prevalence of particular diseases from time to time.

"We pledge ourselves, therefore, to give in every instance which may fall under our care an authentic name of the fatal disease. And we entreat all authorized practitioners throughout the country to follow our example and adopt the same practice, and so assist in establishing a better registration in future throughout England."

Ventilation of Mines

ON May 30, 1837, Mr. Horne contributed to the Institution of Civil Engineers a paper dealing with a method which had been successfully adopted for the ventilation of mines by means of air forced under pressure through pipes. The pipes were 5 inches in diameter and extended a mile, and the ventilation produced, it was said, was complete. A discussion took place on the friction of air and gases passing through pipes of different lengths and diameters. It was stated that the loss on forcing gas through 1,000 feet of pipe amounted to 75 per cent; that is, if 100 cubic feet of gas were delivered through an aperture under a given pressure, only 25 cubic feet under the same pressure would be delivered through a pipe 1,000 feet long. At the same meeting, the Institution was presented with a model of one of the ribs of the centring employed in the construction of Waterloo Bridge.

Darwin on Coral Formations

AT a meeting of the Geological Society, held on May 31, 1837, Rev. W. Whewell, president, being in the chair, Darwin read a paper "On certain areas of elevation and of subsidence in the Pacific and Indian Oceans as deduced from the study of coral formations". After noticing the structure of lagoon islands, encircling reefs and barrier reefs, Darwin went on to give his views on their formation. "The theory which Mr. Darwin then offered," said the *Athenæum*, "so as to include every kind of structure is simply that as the land with the attached reefs subsides very gradually from the action of subterranean causes, the coral-building polypi soon again raise their solid masses to the level of the water, but not so with the land. Every inch lost is irreclaimably gone; as the whole gradually sinks, the water gains foot by foot on the shore, till the last and highest peak is finally submerged. The author then proceeded to offer some considerations on the probability of general subsidences in the Pacific, where many causes tend to its production, and the difficulty of explaining the existence of a vast number of reefs on one level, unless we suppose one mountain top after another becomes submerged, the zoophytes always bringing up their stony masses to the surface of the water. Subsidence being granted, it was shown that a fringing reef would be converted by the upward growth of the coral, into one of the encircling order; and thus by the disappearance of the central land into a lagoon island."

The Restoration of Condamine's Pyramid at Quito

WHEN in 1735 the Paris Academy of Sciences sent an expedition to South America to measure a degree of meridian near the equator, work was begun in a valley of the Cordilleras running about two hundred miles south of Quito. On June 3, 1837, the *Athenæum* contained a note stating that the pyramid erected in 1736 by the celebrated mathematician Condamine and his associates Bouguer and Godin, to commemorate their labours in that part of the world, having been soon after thrown down by the order of the Court of Madrid, was being restored by direction of the President Rocafuerte. The foundation stone was relaid in November 1836, on which occasion an address was given by our countryman General Miller, the Minister Plenipotentiary from Peru. In the course of his remarks, General Miller said: "I cannot pass this opportunity without recalling to mind the names of Juan Jorge and Ulloa—companions of the illustrious Frenchmen—Spaniards who prove that men most distinguished for their love of the sciences are precisely those who most endeavour to promote the welfare of humanity. The report which these two learned men made to the King of Spain, lately published under the title of 'Noticias Secretas' is a production which ought to immortalize them. It is an exact account of the abject and cruel servitude under which the unhappy aboriginal race then groaned, and, I am sorry to say still groan . . . it is to be hoped that the present enlightened President will better the conditions of these unfortunates, and that while he fosters the arts and sciences, he will as efficaciously employ his zeal in abolishing a system of tyranny a thousand times worse than slavery itself." General Miller, who was born in 1795 and died in 1864, served in the Peninsula and North America, was long associated with Chile and Peru, and from 1843 was British consul-general in the Pacific.

Chemistry and the Art of Painting in Enamel

THE June 1837 number of the *Philosophical Magazine* contained an interesting article entitled "Some Account of the Art of Painting in Enamel", by Alfred Essex, the son of William Essex (1784?–1869), enamel-painter to Queen Victoria. In the course of his article, Essex wrote: "To obtain the richness of the master-colourists it is obviously necessary that the painter in enamel should be in possession of colours capable of emulating those of painters in oil. In this, however, the artists of former times were sadly deficient. But, fortunately for this durable and beautiful art the discoveries of modern chemistry have afforded the materials to supply this long-sought desideratum. From three of the metals which till lately were known but to chemists, and which were regarded as curiosities only, namely platinum, uranium and chromium, are already produced four of the richest and most useful of the colours on the palette of the painter in enamel. And doubtless we may look to this source for the means of further improvements."

University Events

Cambridge.—Dr. J. A. Todd, of Trinity College, has been appointed University lecturer in mathematics, Dr. D. Stockdale, of King's College, and Dr. F. B. Kipping, of Trinity College, University lecturers in chemistry and Dr. P. Tate, of Christ's College, University lecturer in parasitology.

It is proposed that Prof. O. T. Jones and Prof. C. E. Tilley be appointed to represent the University at the International Geological Congress to be held in Moscow on July 21–29.

The electors to the Isaac Newton studentships give notice that an election to a studentship will be held early in the Michaelmas Term 1937. These studentships are for the furtherance of advanced study and research in astronomy (especially gravitational astronomy, but also including the other branches of astronomy and astronomical physics) and physical optics. The studentship will be tenable for three years from October 1937. The emolument of the student is £250 a year. Candidates are invited to send in their applications to the Registrary between October 8 and October 14.

The Michael Perkins Prize of £25 is awarded biennially for the best essay, on a subject to be chosen by the candidate, involving original investigation or interpretation of the natural history of animals. Candidates should send their essays to the Professor of Zoology by September 30.

London.—Mr. John Kirk has been appointed, as from October 1, to the S. A. Courtauld chair of anatomy tenable at the Middlesex Hospital Medical School. Since 1930, he has been senior demonstrator of anatomy at University College.

The title of professor of morbid anatomy in the University has been conferred on Dr. W. D. Newcomb, in respect of the post held by him at St. Mary's Hospital Medical School.

The following doctorates have been conferred: D.Sc. in mathematics on B. R. Seth (University College); D.Sc. in zoology on C. H. N. Jackson (University College); D.Sc. (Engineering) on H. J. Nichols (Northampton Polytechnic Institute).

The Petrie Medal for distinguished work in archæology has been awarded for 1937 to Prof. J. D. Beazley, professor of classical archæology in the University of Oxford.

The Dunn Exhibitions in Anatomy and Physiology for 1937 have been awarded to J. W. Paulley (of Middlesex Hospital Medical School) and Philip Harvey (of Guy's Hospital Medical School) respectively.

Oxford.—Dr. A. G. Gibson (Christ Church) has been appointed Nuffield reader in morbid anatomy while holding the office of honorary pathologist at the Radcliffe Infirmary.

Prof. H. J. Paton (Queen's College) of the University of Glasgow, has been appointed White's professor of moral philosophy as from October 1.

M. L. Jacks (Wadham College), headmaster of Mill Hill School, has been appointed to succeed Mr. George Smith as director of the Department of Education as from January 1, 1938.

Societies and Academies

Paris

Academy of Sciences, April 19 (*C.R.*, 204, 1145–1224).

Charles Achard and Maurice Piettre: The plasma of the smooth muscular fibres studied by means of the acetone method at low temperatures.

André Mercier: The equation $\nabla \rightarrow C = \alpha C$.

Paul Delens: The figures of Lemoine and of Brocard in the tetrahedron.

Louis Pasqualini: The conditions of convexity of a variety V_{p-1} of $p - 1$ dimensions plunged in Euclidian space R_p of p dimensions.

Théodore Anghelutza: A property which characterizes conformal transformation.

Paul Lévy: Integral series representing exponentials of polynomials.

Carlos Biggeri: A theorem on the singularities of analytical functions.

Léon Beschkine: A particular solution relating to rings (plane problems).

Rémy Bourgeat, Denis Cahuzac and Jacques Deullin: The phenomena presented by the calibration of velocity meters in calm water.

Pierre Chevenard and Xavier Wache: The intercrystalline corrosion of chrome nickel steels, cold hardened after tempering.

Léon Auger: The frequencies of the sounds given by a cylindrical pipe with beating reed.

Mme. Irène Mihul and Constantin Mihul: The ionization of the upper part of the atmosphere. The varying heights and discontinuities in the reflecting layer are explained as being due to the variation of the electronic density gradient of the ionosphere with height with the position of the sun.

Frantz Perrier: The ionization of air by electrified dielectrics. G. Reboul explains the inversions of current produced by a dielectric discharging in an ionization chamber as the effect of the ionization of the air surrounding the dielectric, but W. Eichenberger considers that the air does not take part in this phenomenon. The author's experiments agree with Reboul's conclusions.

O. Dony-Hénault and A. de Jaer: Electrolysis with a mercury cathode. Study of the effect of stirring the mercury cathode in the preparation of sodium and potassium amalgams by the electrolysis of solutions of sodium and potassium chlorides. A new form of anode was devised (tantalum wrapped up with platinum gauze). This was found preferable to graphite for the high current densities employed.

Albert Grumbach and Félix Taboury: A new phenomenon observed in batteries with one polished electrode. The rôle of the Beilby layer.

Hannes Alfvén: The origin of the cosmic radiation. It is known that the earth and the sun are surrounded with magnetic fields, and if this is the case with the stars the rotation could set up very high electromotive forces. Charged particles accelerated by such voltages could possess the same energy as the cosmic rays. Some of the consequences of this theory are discussed (see also Nature, 138, 761 (1936); 139, 245 (1937)).

Vitomir H. Pavlović: Tesla currents applied to stroboscopy.

Ernst Olsson: The induced predissociation of the tellurium molecule submitted to intense magnetic fields. Study of the changes produced in the absorption spectrum of tellurium vapour by the Bellevue magnet, field 45,000 gauss.

Pierre Barchewitz : The (OH) and (CH$=$) bands of phenol and its derivatives between 6000 A. and 9500 A.

Jean Lecomte : The infra-red absorption spectra of some mono- and disubstituted derivatives of benzene. The symmetry of benzene.

Pierre Jolibois and Robert Bossuet : The quantitative analysis of metallic solutions by means of the spectrograph. The spark spectrum is obtained with direct current (5000 volt circuit), and an apparatus is figured securing a constantly renewed surface of cooled solution.

Jean Roulleau : The influence of the luminous intensity on the sensibility of photo-electric meters.

René Audubert : The activation energy of the photogenic reactions accompanying the thermolysis of hydrazoates. Measurements of the ultra-violet radiation emitted during the thermal decomposition of NaN_3, AgN_3 and $Pb(N_3)_2$.

Jules Guéron : The wall effect in the evolution of aqueous solutions of ferric chloride.

François Olmer : The study by photographic recording of the reduction of oxides of iron in the presence of their natural impurities.

Osias Binder : The green basic copper carbonates.

Roger Pajeau : The bromination of some aromatic compounds in the presence of beryllium and ethyl ether.

André Meyer and Paul Heimann : A new method of synthesis of derivatives of 2,4-dihydroxyquinoline (4-hydroxycarbostyril) starting from malonic esters and aromatic amines.

Antonio de Medeiros Gouvêa and Georges-Zbyszewski : New observations on the Quaternary of the coast of southern Portugal between Cap Sagres and the mouth of the River Odesseixe.

Constantin T. Popesco : The prolongation of the duration of life in the aubergine grafted on the sweet almond.

Pierre Chouard and René Castau : The tuberization of stems and hypocotyls by longitudinal diffusion of hetero-auxine.

Basile Luyet : The mechanism of cell death by high pressures. The intensity and duration of the lethal pressures for yeast. The yeast cells do not all die at a given pressure : the lethal pressure commences at about 4,000 atmospheres, under which some cells die in some minutes ; at 7,000 atmospheres all are killed in some seconds.

Jean Louis Perrot : The impregnation chamber of *Helix pomatia* and the presence of spermatozoids at this level.

Léon Képinov : The synergy of adrenaline and of the pituitary hormone. The role of the pituitary hormone in the mechanism of the glycogenolytic action of adrenaline.

R. Jonnard : The magnetic susceptibility of normal and pathological blood serum.

Marcel Lévy Bruhl, Georges Ungar and Mlle. Alberte Levillain : The production by means of bacteria, starting with urea, of a substance identifiable physiologically with histamine.

Moscow

Academy of Sciences, (*C.R.*, 14, No. 3, 1937).

M. Kravčuk : Some approximations in the generalized problem of moments.

J. Geronimus : The problem of coefficients for limited functions.

B. A. Wenkov : The automorphic group of an indefinite quadratic form.

P. A. Čerenkov : (1) Visible luminosity of pure fluids under the influence of hard β-rays. The luminosity is caused mainly by the electrons with β greater than 0·8. (2) Angular distribution of the intensity of the luminosity caused in pure fluids by γ-rays.

I. Frank and Ig. Tamm : Coherent visible radiation due to fast electrons passing through matter. A theory is put forward and supported by calculations that an electron moving in a medium radiates light even if it is moving uniformly, provided that its velocity is greater than the velocity of light in the same medium.

F. M. Šemiakin : Colour reactions of rare earths with alkaloids (3). New colour reactions with morphine and brucine are proposed. The brucine reaction may be used for colorimetric determination of cerium.

A. A. Grünberg and D. I. Riabčikov: Application of oxidometric titration for the determination of the constitution of complex compounds.

K. K. Matveiev : Occurrence of nickel in the biotite shales of the Ural emerald mines and of other emerald deposits.

A. Lebedev : Lead-bearing tourmaline from the Maly Khingan.

P. A. Kosminskij and N. P. Eršova : A new eighth linkage group in *Bombyx mori* L.

P. A. Kosminskij and N. A. Mordovkina : Inheritance of yellow colour in cocoons of *Bombyx mori* L.

Z. F. Fedorova : An investigation of inversions in the third chromosome of *Drosophila melanogaster*, and the production of new inversions which completely suppress crossing over along its whole length.

S. O. Grebinskij : Accumulation of citric acid in makhorka (*Nicotiana rustica* L.).

E. D. Bouslova and V. N. Lubimenko : Influence of luminous induction on the development of *Perilla ocymoides* (1).

V. N. Lubimenko and E. D. Bouslova : Contribution to the theory of photo-periodicity (2).

Vienna

Academy of Sciences, February 25.

E. Abel and J. Proisl : Mechanism of the lead chamber reaction. The reaction between nitric and sulphuric acids under various conditions.

Karl Vanek : Radius of curvature of plane curves.

K. W. F. Kohlrausch, A. Pongratz and R. Seka : Studies of the Raman effect (65). Various organic substances.

K. W. F. Kohlrausch and A. Pongratz : Studies of the Raman effect (66). Nitrogenous substances.

Karl Krammer : Reflection of α-rays of radium C' by heavy nuclei.

Otto Pesta : Ponds in the East Alps.

Rudolf Zimara : Observations on mammals from New Guinea.

Otto Koller : Report of a second zoological expedition to Asia Minor in 1936.

March 4.

M. Pestemer and E. Mayer-Pitsch : Influence of substituents on the ultra-violet absorption of two conjugated benzene chromophores.

O. Fruhwirth : Study of the association of water by measurements of dielectric polarization.

M. Pestemer and O. Fruhwirth : Ultra-violet absorption and orientation polarization of the binary systems acetone-benzene and nitromethane-carbon tetrachloride.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Lecturer in Mechanical Engineering in Armstrong College, Newcastle-upon-Tyne, 2—The Registrar (May 31).

Demonstrator in Mathematics in the City and Guilds College—The Secretary, Imperial College of Science and Technology, Prince Consort Road, South Kensington, S.W 7 (May 31).

Museum Assistant for the Woolwich Borough Museum—The Town Clerk, Town Hall, Woolwich (June 4).

Assistant in Biology and Pharmacy in Dundee Technical College—The Clerk and Treasurer, Bell Street, Dundee (June 5).

Editor of *Science Abstracts* (Electrical Engineering Section)—The Secretary, Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2 (June 7).

Curator in the Horniman Museum, Forest Hill, S E.23—The Education Officer (G.P /M), County Hall, S.E 1 (June 10).

Assistant Lecturer in Physics in the University of Manchester—The Registrar (June 12).

Assistant Lecturer in Geography in the University of Bristol—The Registrar (June 14).

Forest Officer in the Forest Service of Burma—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (June 18)

Research Engineer for the Institution of Automobile Engineers, Great West Road, Brentford, Middlesex—The Secretary

Chemists for the War Department Chemist—The Under-Secretary of State (C.5), The War Office, S.W.1 (quote Appts./30).

Assistant Secretary of the Council for the Preservation of Rural England—The Secretary, C.P.R.E., 4 Hobart Place, S.W.1.

Assistant Civil Engineers in the Air Ministry—The Secretary (W.9), Room 712, Air Ministry, Adastral House, Kingsway, London, W C.2.

Instructor Lieutenant (mathematics, chemistry, physics or engineering) in the Royal Navy—The Director, Education Department, Admiralty, S.W.1.

Assistant Divisional Engineer in the Sudan Irrigation Department—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S.W.1.

Assistant Teacher of Electrical Engineering and Assistant Teacher of Mathematics in the Acton Technical College, High Street, W.3—The Principal (June 4).

Demonstrator in Mathematics in the University of Cambridge—Dr. H. M. Taylor, Clare College, Cambridge (June 5)

Lecturer in Mechanical Engineering in the Chesterfield Technical College—The Clerk to the Governors (June 7).

Assistant Lecturer in Chemistry and Botany or Zoology or Physics in the Studley Horticultural and Agricultural College for Women, Warwickshire—The Secretary (June 7).

Demonstrator in Geology in the University of Cambridge—Dr. F. C. Phillips, Department of Mineralogy and Petrology, Downing Street, Cambridge (June 8).

Lecturer in Chemistry and Lecturer in Mechanical Engineering in the Northampton Polytechnic, St. John Street, London, E.C 1—The Secretary (June 14)

Head of the Department of Electrical Engineering and Physics in the Royal Technical College, Salford—The Director of Education, Education Office, Salford, 3.

Lecturer in Engineering in the Shrewsbury Technical College—The Clerk to the Governors, County Buildings, Shrewsbury.

Part-time Evening Instructors in Engineering, Physics and Mathematics in the Northampton Polytechnic, St. John Street, London, E C.1—The Secretary.

Freedom of the Mind

OUR civilization is clearly separated from all that have gone before by its reliance upon science. Science makes certain demands on social environment, and among the chief of these is surely freedom of the mind. Without such freedom, our scientific system could not exist or progress : without it, representative institutions cannot be maintained. Milton saw these things very clearly, and it was in the early days of the Royal Society that he wrote :

> ". . . True Liberty
> . . . always with right Reason dwells
> Twinn'd, and from her hath no dividual being.
> Reason in Man obscured or not obeyed
> Immediately inordinate desires
> And upstart passions catch the Government
> From Reason, and to servitude reduce
> Men, till then free."
> "Paradise Lost", Book XII, 83-90.

We are witnesses of the simultaneous destruction in several parts of the world of the twins—liberty and reason—and the consequent deterioration of science. We see reason not only obscured and disobeyed but even ousted by unreal creatures of the imagination—'racial consciousness', 'national self-sufficiency', 'the leadership principle'—or one or other of the chimæras of the totalitarian States. Some peoples have been caught thereby from reason, so that the desires and passions of their Governments have already reduced men to servitude, and are on their way to reduce science to nothingness. We have seen a great country, until of late rightly proud of its universities and its scientific achievements, abandoning its belief in reason, destroying the careers of a fifth of its scholars and, by rendering the position of all insecure, humiliating the profession of learning itself and lowering the whole standard of its civilization.

For, let it be remembered, civilization must depend upon a small minority. Our present civilization is upheld by the critical and creative efforts of a few, whose judgment and knowledge ultimately determine the values of the rest. Only in an atmosphere of freedom can such men make their contribution to their own communities and to the world. The need for the Society for the Protection of Science and Learning to save for the freer parts of the world the learning rejected by these slave States, is the measure of the destruction of freedom.

It is an experience, gathered from history, that the great periods of intellectual activity follow the coincidence of the discovery of important new facts with the wide extension of a sense of personal liberty. Of this relation a fortunate illustration is provided by the seventeenth century, which saw both the foundation of English ideas of liberty and the establishment in England of the scientific disciplines. On these two foundations have been built most of the good things that make up our national life. The other democracies—and it is among democracies only that science seems now to flourish—have had a comparable experience.

The rise in the social valuation of freedom of the mind has, therefore, been of incalculable importance for science. Unfortunately, this great movement has had its own vicissitudes and has brought with it its own dangers. In the eighteenth century, science was still confined to a very small class, within which free opinions passed as common intellectual currency. With the emergence of the liberating influences of the French Revolution, such opinions came to be greatly feared. Active measures were taken to stifle them when expressed freely, though if buried in expensively printed works the Governments of their day could afford to treat them with contempt. When the 'atheist' William Godwin brought out his "Enquiry concerning Political Justice and its Influence on Morals and Happiness" in 1793, it escaped prosecution only because the authorities supposed that little harm could be done by a three-guinea publication! Soon, however, the technical and industrial triumphs of science won it new prestige, so that during the later Victorian age, freedom of the mind came to be less feared. Gradually there came another change. With compulsory State education, the proportion of literates increased enormously. Moreover, new channels were found for the passage of ideas. Cheap printing, a new technique of daily journalism, and then the cinema and the wireless, have increased again the danger of ideas to those who fear them. Inordinate desires and upstart passions have now again caught Governments from reason, and man has again been reduced to servitude. The very products of science have been used to suppress the spirit of science.

Of all forms of checks on reason, that on the universities is the most dangerous and destructive, for it strikes many of those best equipped to determine social values. The totalitarian States have not failed to perceive this. National Socialism is the form of totalitarianism that has been most destructive of science, and National Socialism is, as its exponents never tire of explaining, an attempt to exalt instinct at the expense of reason. Last year, at the celebration of the so-called 'jubilee' of the University of Heidelberg, which was timed to coincide with June 30, the day of the great political massacre of 1934 in Germany, the Minister of Education, Herr Rust, delivered a speech in which he exalted the so-called 'racial instinct' over the disinterested pursuit of scientific truth. The day of the supremacy of the intellect, he assured us, is over. Under National Socialism, through its agent, Herr Rust, who has no sympathy with the great tradition of free thought, the universities have been regimented and those who do not share national socialist views have been eliminated. Science has thereby been degraded and German men of science have been made subservient to the engineers of a ruthless political machine.

In Germany, science has always been essentially a product of university officials, and the amateur has played a minor part in its intellectual life. But now, not only are its university officials spied upon and kept under a strict rule, but even private workers dare no longer express their opinions. The printing press is as much under control as are universities. What may and what may not be published is determined by men who have repeatedly and publicly expressed their opposition to freedom of the mind. The result has been a general deterioration in the quality of scientific publications in every department from mathematics to anthropology.

Apart from this, what can be said of the scientific literature that has been discouraged or suppressed? What of all that great output of the German intellect that we might have expected during the last four years? Some of it has appeared in foreign countries as the work of men whose continued activity has been rendered possible by foreign hospitality, and what Germany has lost other countries have gained, but much of the potential output of German men of science has been altogether lost. Nor must we forget the great episode of the 'Burning of the Books' which swept as an epidemic over the university towns of Germany. That event will be long held in memory as a sign of what may happen to men by whom reason is disobeyed and the desire for liberty is lost. It is three centuries since Milton wrote words that are as vivid now as then:

> "Books are not dead things but do contain a potency of life in them to be as active as that soul was whose progeny they are. Who kills a man, kills a reasonable creature; but he who destroys a book kills reason itself, kills the image of God. We should be wary therefore what persecution we raise against the living labours of public men, how we spill that seasoned life of man, preserved and stored up in books; since a kind of homicide may be thus committed, sometimes a martyrdom; and if it extend to the whole impression, a massacre, whereof the execution ends not in the slaying of an elemental life but strikes at the breath of Reason itself; slays an Immortality rather than a Life."

Milton saw that freedom of thought is possible only under free social conditions. Many British men of science appear to be indifferent to the application of this essential principle of progress. They hold aloof from the great social questions of the day and seem to disregard the activities of forces destructive to the very world of science. We would not wish men of science to become politicians, but surely they should indicate with no uncertain voice their determination to resist those dark forces of unreason implicit in the regimes that would destroy scientific ideals.

Mathematical Biology

Biologie mathématique
Par Prof. V. A. Kostitzin. (Collection Armand Colin: Section de biologie, No. 200.) Pp. 223. (Paris: Armand Colin, 1937.) 13 francs.

THIS is an admirable little book. It does not pretend to teach a biologist mathematics: it does not deal with the ready-made mathematics (so to speak) of the snail-shell, the fir-cone or the honeycomb: it opens our eyes to a variety of biological problems which lie remote from elementary or conventional mathematics, but may nevertheless be brought under mathematical treatment with great advantage. To learn, *ad hoc*, this or that chapter of mathematics, does a biologist little good; all he wants—and what a deal it is—is to lap up something of the spirit of mathematics, to learn how the mathematician economizes thought by his symbols, simplifies argument by his equations, starts from unequivocal postulates, uses an ancient and traditional logic, and has his own unmistakable ways of saying what he knows and what he wants to know. These are the advantages, or some of them, which bring one science after another under the spell and dominion of mathematics.

The first-found alliance between mathematics and biology came by way of 'statistics', when Quetelet, prompted by Malthus, studied the growth of a population, and dealt with the stature and proportions not of men but of mankind. From Quetelet's right hand Raymond Pearl, after rediscovering Verhulst's 'logistic law', raised up the new science of demography; from his other hand Karl Pearson, valiantly helped by Weldon to begin with, took the new art and science of biometrics. The study of the growth of a population, or of the mean growth of an individual, is in neither case an easy thing. What population, higher than a cluster of yeast-cells, can be deemed simple and homogeneous? By what graph or formula can we hope to represent a creature's growth, which begins in its mother's womb, is fed by its mother's milk, bends under the sexual hormones, has its spell of untrammelled vigour, and lingers on under the burden and the disabilities of age? We must start afresh, with easier and simpler things. Imagine a population not even approximately homogeneous, but definitely heterogeneous, where half is at war with the other half, and one half is the other's inevitable and helpless prey; or again, imagine a population consisting of host and parasite. In either case, the 'growth of the population'—of the mixed or heterogeneous population—is a theme for the mathematician. Here and round about, in a class by themselves, to be dealt with after a fashion of their own, lie many curious problems; and Dr. A. J. Lotka on one side of the Atlantic, and Prof. Vito Volterra on the other, were the first to see their mathematical bearing and to devise the differential equations to which they lead. This, then, is the main but not the only theme of Dr. Kostitzin's little book, which is the first to deal in a general way with this class of problems. To the mathematician the book looks like a useful collection of examples of differential equations; to the naturalist it is obviously a well-chosen set of problems in evolutionary biology. When we realize that it is both of these rolled into one, we begin to see what an eye-opening book it is.

When we study a 'mixed population', it must be no vast and complicated 'fauna'; we may be well content if we can deal with some local association of two or three species whose lives are plainly interlinked together. Even so, their complex and changing interrelations might seem beyond the scope of mathematics, and the fact that they are not so is nothing short of a great discovery. We begin by learning to symbolize the conditions of existence by coefficients of vitality and mortality; we must be prepared for critical changes when one constituent of a population has greatly dwindled or preponderantly increased; we cannot fail to recognize a tendency towards equilibrium—but we end by discovering that equilibrium is never to be attained! An everlasting ebb and flow, a mean level and a tide, is our nearest approach to equilibrium. A typical illustration, the very one which led to what we call Volterra's law, is that of two associated fishes, one feeding on the other—call them shark and cod. While the shark are few the cod multiply; when cod are plentiful the sharks wax fat and multiply in turn; the predaceous horde plays havoc with the shoals of cod, and at length the poor sharks go short of food and their numbers dwindle. We find analogous cases everywhere. The whalers equip fleet after fleet while whales are plentiful; sooner or later the whales are reduced to vanishing point, the trade ceases to pay, and the few whales left have time to breathe and breed again; and so on, and so on, in a long, slow cycle of trade. But so simple a differential equation is soon complicated, the worse for the whale. The older whale-fishery was so eked out by seals, narwhals, walrus, bottlenose and beluga, that it went on long after the whales had grown too scarce to pay the cost of a voyage. The modern whale-fishery, again, is or was based on the great blue whale ; but increasing scarcity confers no respite or immunity on this poor monster, for less valuable species live alongside, and serve to keep the industry in being and prolong the epoch of destruction.

The lack of permanent equilibrium, the inevitable flux and reflux, may be seen everywhere : in the battles of the bulls and bears, the alternation of slump and boom, the vicissitudes of party politics and the hopeless dream of a world where there shall be no more war. From Volterra's first equation, Dr. Kostitzin (following M. E. Fischer-Piette) takes us to a sea-shore abounding in mussels, but starfish came in from every side (just as they do on oyster-beds), and the mussels soon grew few ; in the mixed population were also dog-whelks (*P. lapillus*), which feed on mussels and on barnacles, by choice the latter. In a good mussel-year mussel-spat covers everything, the rocks, the barnacles and the old mussel-shells ; the whelks turn, perforce, to a diet of mussels, and flourish exceedingly. The mussels diminish, and leave the rocks bare for a new invasion of barnacles ; and in a year or two, as these grow up, the whelks forsake the now scanty mussels, and come back to barnacles as their proper food. All these facts and phases can be easily symbolized If p_1, p_2, p_3 be the population of barnacles, mussels, whelks, then (for example) to begin with, p_1^1 (the initial population of barnacles) $= \varepsilon_1 p_1$ (where ε is a coefficient of vitality) $- h_{13} p_1 p_3$ (where h_{13} is a coefficient of interrelation, and symbolizes the effect of p_3 on p_1) $- h_{12} p_1 p_2 - h_{11} p_1^2$ (this last being the fight among the barnacles themselves for food and foothold). For each phase, for each scene of the drama so to speak, we have a new set of such equations as these ; and these several groups of differential equations combine, pass from equilibrium to inequilibrium, and show the ups and downs of one species after another. After this simple fashion, without talking over our heads, Dr. Kostitzin shows us how his differential equations are built up. It is not his fault if their solution, even their qualitative solution, turns out to be a harder matter.

The wolf, the goat and the cabbage : the great carnivorous lizards, the little herbivorous mammals and the normal vegetation of Komodo : the little mite-populations which survive when both are few, but of which one goes under when the other multiplies : the various associations of infusoria, *Paramœcium, Bursaria, Didinium* : these are a few of the cases to which Dr. Kostitzin fits his protean differentials. From vague and transitory associations we pass on to more stable relations of symbiosis and of parasitism. One of these—we never dreamed of old of its being open to mathematical analysis—is that of *Adamsia* and *Eupagurus*, the sea-anemone and the hermit-crab. The larvæ of these are free and independent, and each lives in its own country ; but we must not suppose that mere chance, apart from any pre-adaptation or predisposition, brings them together. The partnership brings its recognizable advantages, all the greater the earlier it is formed ; and while other hermits and anemones may associate temporarily and fortuitously, in this particular case they so draw together as to be at last inseparable.

The growth of a population prepares us for that of an individual organism, which is indeed a population in itself, a cluster of organs or a multitude of cells. These, *mutatis mutandis*, are alike to a first approximation ; but, to take only one of many differences, reproduction, which should be a function of all the individuals of a population, is by no means common to all the cells of a multicellular individual. The author points out, in passing, that the growth of man, from youth to age, is singularly complete and unusually instructive ; for we follow it even into extreme old age, all through the phase of senility which wild Nature cuts away, but in man alone is permitted and assisted to endure.

A short chapter follows, on the forms of living things—a somewhat trivial chapter, below the level of the rest of the book ; and the book closes with a chapter on evolution, a short one but long enough to let the author's originality appear. He points out the cardinal distinction between local and general evolution. In the world at large things really tend towards equilibrium, dropping down into their most probable state : entropy goes on increasing, and all the wheels are slowly, slowly, running down. But this does not hold for all the local, isolated cases ; the less probable gets its chance now and then. We must on no account suppose, as some did in early Darwinian days, that evolution is going on here, there and everywhere, that organisms are everywhere and evermore growing better, finer and more beautiful ; in the vast duration of geologic time and the vast range of the living, a notable step in organic evolution is always a rare and most unlikely thing. This being so, life is no negation of the law of entropy ; it only illustrates and confirms it. What, then, lies at the root of evolution ? To begin with, there is the principle of selection, the struggle for existence, through any or all of those things that in our various equations add ever so little to the coefficients of mortality. Every grade of advantage and disadvantage, every stage of disqualification up to extinction itself, may be symbolized and analysed mathematically; of selection as a factor in evolution there can be no doubt at all. Next comes the occurrence of mutations. As Jachin and Boaz, so are mutation and selection the two pillars of the house:— Given these two, the origin of species is so far explained. But when all is said and done, then ignorance lays hold of us again. Our author assumes, apparently, that the origin of species is an unlimited process and that species (or 'phenotypes') vary all but continuously and without end: but the fact is we begin by marvelling at the wealth of species in the world, and end by realizing that, in contrast to an infinite variety, they are astonishingly few. Mutation has its narrow limits, so far as ever we see: and the science of genetics does not explain the mechanism of evolution. Again, when mutations do occur, what leads to them? What chromosomes look like we know well; But what are they, and what do they really do? Biology will have come at last into its kingdom when we shall have found a simple answer to these and a few other simple questions.

D'ARCY W. THOMPSON.

Britain's Scenic Beauty

The Scenic Heritage of England and Wales
By O. J. R. Howarth. Pp. xxv+190+48 plates. (London: Sir Isaac Pitman and Sons, Ltd., 1937.) 8*s*. 6*d*. net.

THE Councils for the Preservation of Rural England and of Rural Wales have rightly judged that their efforts may be strengthened by interesting senior pupils of our schools in that beauty which is such a feature of Great Britain in spite of the disfigurements that have been multiplied so disastrously since industrialism classed our cities under Dr. Jacks's general name of 'Smokover', and 'bungalitis' spread along so much of our coast. To the appreciation of scenic beauty our minds, variously stored with early memories and the results of study of many kinds, may bring diverse contributions, but these associations are beyond standardization and it is difficult to communicate them far and wide, so Dr. Howarth has in the main focused this book upon sheer physical characteristics, while appropriately bringing in man-made features in many connexions. Dr. Vaughan Cornish, with the artist's eye, sees that our venerable trees that have been allowed to grow in their own way, instead of being lopped as are so many on the Continent, are a splendid part of our heritage and essentially a British feature, and he has striven in an introduction to suggest the changes of the scene around the year.

Dr. Howarth bases his study upon the geology of our country, which is to such a remarkable, almost a unique, extent an epitome, in miniature, of the story of the rocks of the world; but his chapter on historical aspects exhibits a wise perspective, illustrated as it is by "Long Meg and her Daughters", for the prehistoric; Fountains Abbey and Salisbury for the ecclesiastical; and Charles Darwin's garden at Downe for the scientific phase of our social evolution. There is a very soberly written tribute to London that may be more effective than the more enthusiastic account of our incomparable capital that some of us would have composed. It is good to see that the author has learned from Lethaby. The Weald, the Chalk, the East, the Hampshire Basin, the Secondary Limestones, the Midlands, the Western Marches, the South West, Wales, the Pennines, the North-east and the Lake District are treated successively, and there are forty-eight full-page illustrations from well-chosen photographs. One hopes that the book may spread both among the general public, and, in particular, the motoring and the hiking sections of the community, as well as in the schools, and that second and third editions may soon be called for. If that is the case, the promoters of the book will be well advised if they increase still further the number of good illustrations. It is probable that we can do most in the desired direction by educating the eye, and one looks forward to such a development of this book, without increase of price, as will make pictures its mainstay, though our appreciation of the thoughtful character of the text is likely to grow.

The low and dissected plateau of newer rocks was the basis of our English nationalism and of the Puritan tradition, now become essentially conservative. Its quiet scenery, its picturesque villages, too often still needing better sanitation, its trees still shading the parish churches that are such a feature of England, all help to give it a character of its own that John Constable expressed as few others could. The wilder areas of older rocks, the south-west, Wales and the north, all with stronger infusions of the Celtic heritage that is nowhere entirely wanting, were of old the basis of warlike vigour and regionalism, of the Cavalier tradition and the associations of John Peel. But it has been their strange fate to be transformed, in patches here and there, into the industrial slums that sprawl over the West Riding, South Lancashire, the Black Country, and what were once gems of beauty like the Rhondda Valley in South Wales. So it comes about that nests of ancient survivals and hives of nineteenth century industry, not a few now half derelict, are interspersed. And now industry is spreading into the old England of the newer rocks. Have we learned our lesson ? Dr. Howarth is hopeful about Corby.

Since 1895, many beauty spots and some four thousand monuments of our past have been placed under the protection of trusts concerned solely with our heritage of beauty and our historic record. This is a worthy record of piety, but it suggests some uncomfortable questions. What will our successors preserve as the records of the Britain of industrial and commercial imperialism ? Shall we put a fence around some condemned slum area in Manchester or London and call it a historic monument ? Might we not dedicate the slagheaps and discarded railway station of Landore ? Are we not perhaps on the way towards sublimating Crewe Junction into the realms of history ? Can we not consider a recent suggestion to move the great majority of the statues of booted and frock-coated or robed worthies that encumber rather than adorn our streets and squares into out-of-the-way corners of parks ? H. J. F.

The Preservation of Food

Canning Practice and Control
By Osman Jones and T. W. Jones. Pp. xii +254 + 65 plates. (London: Chapman and Hall, Ltd., 1937.) 25s. net.

THE great changes in the conditions of life brought about by the industrial developments of the last century have necessitated an increased consumption of preserved foods. Of the various processes used in commercial practice, that of sterilizing in hermetically sealed tinplate containers—more commonly referred to as 'canning' —has rightly assumed pride of place, and foods properly preserved in this manner are not only in a form convenient to the housewife but are also at least as nutritious as similar products cooked in the home. The steady growth of the canning industry in size and efficiency has been aided throughout by researches which have covered a wide field, ranging from investigations connected with the growth of suitable raw products through the many problems associated with the technical processes of industry to studies of a more academic nature in bacteriology and metallurgy. It is a little difficult for the general food chemist to keep track of this widespread literature, and for that reason we must welcome any attempt to consolidate the existing knowledge of the science and art of food canning.

The title of the present book is perhaps a little misleading, as there is a noticeable lack of balance between the treatment of the sections on canning practice and laboratory control, and it seems a pity that the authors have limited their discussion of the practical side to about a fifth of the book. On the other hand, the chapters dealing with scientific control as applied to the duties of the works chemist or bacteriologist are more comprehensive than would appear to be necessary.

After a preliminary chapter dealing with the statistics of production and consumption of canned foods, the authors go on to describe the construction and equipment of a cannery and then give a brief outline of canning processes in general. The latter chapter can scarcely fail to be disappointing to the practical canner on account of the many very obvious errors it contains. To take but one example, it is incorrect to say that the majority of canners make their own cans, as almost every firm engaged in the canning of fruits and vegetables obtains its supplies from one of the companies which specialize in making the standard open-top can. Nor are the cans made by these companies supplied in the flattened form, this method of packing being intended only for export purposes.

Adequate space is given to methods of chemical analysis, but greater stress might have been laid on the difficulty of estimating copper in the presence of tin and iron. The bacteriological side of laboratory control occupies about a quarter of the book, and much of the descriptive matter concerning the elementary aspects of the subject could have been omitted with advantage.

The book contains much material of interest and value to the food chemist, the cultural notes on the principal food spoilage organisms being particularly worthy of mention. The text is well supplied with references, and there are many excellent illustrations, the numerous photomicrographs of bacteria being remarkably good.

F. H.

Einführung in die klassische Elektrodynamik

Von Dr. Johannes Fischer. Pp. viii + 199. (Berlin: Julius Springer, 1936.) 13.80 gold marks.

THIS small volume on the classical electric theory contains a general, but not very novel, survey of the portions of the mathematical-physical theory which are still relevant in the broader technical applications of the subject. Starting with electrostatics, the author carries his readers carefully through all the important physical ideas underlying the static field theories of Maxwell and Faraday, including the theory of dielectrics. Following this, he introduces in a small chapter the field and energy relations of the magnetostatic field, basing himself on the analogy with the electrostatic field. The first section of the book closes with a brief survey of the kinematical problems of current flow in conducting media.

In the second section, the usual laws of electrodynamics are discussed in some detail, together with their application in current theory and its bearing on the problems of electro-technics. The treatment is based on the ideas underlying Maxwell's equations, which are given in explicit form and used in the last chapters to develop the main ideas of the theory of the propagation of electromagnetic disturbances.

The author lays some stress on an endeavour to circumvent the difficulties in the assumptions underlying presentations of this subject via the æther theories, but one cannot but feel that he has been successful only to the extent to which he has avoided discussion of these difficulties. He gives, for example, the Kelvin-Larmor discussion of the polarization constituent of the total electric displacement, but says nothing whatever about the other constituent—the 'æthereal' one. His use also of the magnetic circuit to overcome some of the difficulties of the magnetic formulation really introduces more difficulties than it overcomes. He still fails to realize that the difficulties in the old-fashioned formulation of the magnetic relations all result from the use of the fundamentally faulty electric-magnetic analogy. It is also noticed that, like all Continental writers, the author still adheres to the form of the Maxwell stress deduced originally by Helmholtz by an argument which Larmor showed more than forty years ago to be physically unsound.

These are, however, perhaps small blemishes on a very brave and generally successful attempt to present in about 170 pages a reasoned account of a subject which most of us feel demands nearly four times this space. G. H. L.

The Annual Register:

a Review of Public Events at Home and Abroad for the Year 1936. Edited by Dr. M. Epstein. Pp. xii + 304 + 190. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 30*s.* net.

THERE can be few events in the political or social history of Great Britain or the Empire that escape record in the pages of this widespanned annual. A dispassionate review of the year ranges over a field wide enough to include reduction in telephone charges and non-intervention in Spain. The Dominions and India follow, and then comes a long section treating of foreign history, preceded by several pages on the League of Nations. A few States have had a year so happily uneventful as to escape inclusion in the survey, but this is exceptional.

Part 2 of the book has the usual arrangement of a chronicle of events; a retrospect of literature, art, science, finance and law. Science of the year is reviewed in epitome: much is mentioned in an extremely condensed form. Two among other general trends are noted: the growing disquiet among men of science at the frustration and prostitution of science for anti-social ends, and also the clear realization that advance in scientific thought can only come through intellectual freedom. Among the public documents published in full is the new Soviet constitution. An admirable index much facilitates reference.

The Tropical Garden

Its Design, Horticulture and Plant Materials. By Loraine E. Kuck and Richard C. Tongg. Pp. xi + 378 + 16 plates. (New York: The Macmillan Company, 1936.) 12*s.* 6*d.* net.

THE authors of this volume are writing primarily for gardeners in the Haiwaiian Islands, though, as the climate in this part of the Pacific is fairly typical of the moderate tropics everywhere, the information they give will be of use to a much wider public. They treat their subject from two angles, design and choice of suitable plants. In twenty-three chapters these two aspects are fully explored. The book is written in a popular and lively style, but is, nevertheless, scientifically accurate—as is to be expected from the list of helpers given in the preface.

The numerous photographs add to the value of the text, and the volume is well produced. A greater use might, however, have been made of italics for Latin names. The volume is a welcome addition to the rather meagre list of works on gardening in the tropics.

Technical Electricity

By H. T. Davidge and Robert W. Hutchinson. Fifth edition. Pp. x + 520. (London: University Tutorial Press, Ltd., 1936.) 12*s.* 6*d.*

WE can commend the fifth edition of this book highly. It is easy to understand, has been thoroughly brought up to date and will appeal to students, teachers and engineers. The answers are given to the problems set and many of them are completely worked out. Electrical engineers can refresh their memory about the fundamental facts of atomic disintegration, thermionic valves and photo-electric cells. They will even find something instructive said about tariffs and the British Grid. We think, however, that the authors' résumé about the laws governing the sizes of fuses and the temperature rise in cylindrical conductors could have been improved. They have not laid sufficient stress on the important part played by thermal convection currents in this connexion. A better rule than the one given is that, within certain limits, the fusing current varies as the 1·25th power of the radius of the wire. A proof is given by Russell (*Proc. Phys. Soc.*, 22, 450).

The Bermuda Oceanographical Station

By Prof. E. W. MacBride, F.R.S., Chairman of the Advisory Committee of the Development Commission on Fishery Science

THE British Government has decided to grant a sum of money in order to establish and carry on for a period of five years an oceanographical station in the Bermuda Islands. The management of the station has been vested in a Committee, of which I have the honour to be chairman, nominated by the Royal Society, and hence it seemed appropriate that I should endeavour to give to readers of NATURE an account of the reasons which led to the decision to found the station and the objects which it is hoped to attain by its activity.

At a time when taxation is so heavy in the United Kingdom, some members of the general public may think it a piece of quixotic extravagance to subsidize what might be regarded as a Colonial institution. The answer to this objection is that the station is not being established for the benefit of the Bermuda Islands but to help British fisheries.

At one time it was thought that by the artificial hatching of the eggs of our edible fish, and by then releasing the fry in the coastal waters, the fisherman's catch could be increased. Not so very long ago, haddock fry were thrown into the sea off the east coast of Scotland and herring fry were released in Loch Fyne, just as to-day lobster fry are poured into the sea near Barra Head in the Isle of Man. It was that brilliant zoologist and oceanographer Prof. Johan Hjört who first clearly showed the futility of this procedure. He pointed out that if one counted up the total number of fry hatched at one of the fishery stations and expressed this total in terms of the number of females necessary to produce them, the whole work of the station was equivalent to adding at enormous expense a few dozen female fish to the teeming millions already in the sea. The main service which fishery research can render to the fisherman is to tell him where to find his fish and what the magnitude of the catch in the coming season is likely to be.

In certain cases, however, the fishery expert can perform the additional service of proving that in some areas of the narrow seas, such as the Flemish Bight, too heavy a toll is being levied on the young fish and that the remedy for this is to make it illegal to sell fish below a certain size, and to insist on the nets used having a certain width of mesh so that the smaller fish can escape through them.

Prof. Johan Hjòrt was perhaps the first to predict successfully the future yield of edible fish and to find spawning grounds off the coast of Norway hitherto unknown. All honour should be given to him for leading the way; but as he would be the first to admit, the conditions of the North Atlantic near the coast of Norway are simple compared to those obtaining in the North Sea, in the English Channel and in the Western Atlantic where it bathes our shores. Nevertheless, by hard continuous labour and the piling up of innumerable data, which constitute the only road to success in zoological science, the fishery experts of the Scottish Fishery Board and those of our own Ministry of Fisheries, under the guidance of the chief scientific adviser, Dr. E. S. Russell, have succeeded in predicting the yield of the haddock fishery in Scotland and of the herring fishery off the East Anglian coast, in each case about six months ahead. In other areas, baffling and hitherto unsolved problems confront them. One small example of these problems may be given.

For many years, Mr. E. Ford, now vice-director of the Plymouth Marine Biological Station, has been investigating the herring fishery in the south-west area of the English Channel. He has found that during the past five or six years there has been a steady decline in the yield of this fishery and that this decline has been due to the fact that the fishermen have been drawing on the same stock of fish, which every year has been growing older and fewer in numbers. Far too few herring fry are entering the Channel to replace the losses in the older fish. The cause which Mr. Ford has found for this deficiency is the falling off in the stream of highly saline Atlantic water entering the Channel. This water is rich in phosphates and supports a large number of micro-organisms on which the fry feed. Mr. Ford has strong suspicions that the fry which should have entered the Channel are to be found farther afield; and that the fishery which the men of Devon and Cornwall exploited is now to be sought for off the south coast of Ireland.

This brings us to the central problem of British fishery research, namely, the cause of the periodic variation in the pulse of warm Atlantic water—popularly known as the Gulf Stream, though the actual Gulf Stream cannot be distinguished east of Newfoundland—which washes our shores. If we could solve that problem, we should be able to give our fishermen a guidance out of all proportion greater than that which has been so far afforded to them. The so-called Gulf Stream, as is well known, travels in a north-east direction from the coast of Florida and pours through the Faeroe Channel, north of the Shetlands, into the North Sea. Strange to say, the stream, when strong, does not bring with it an abundant fishery but the reverse. Our most valuable food-fish loathe it like poison. Poor catches of herring, haddock, plaice and sole go along with a strong Gulf Stream. This stream brings with it enormous numbers of jelly-fish of all kinds and of gelatinous algæ which are avoided by our fish. The cold current which streams down the coast of Norway—unlike the Channel water—is very rich in phosphates and gives support to an enormous multitude of minute Crustacea on which herring, haddock and plaice feed.

As most people are aware, a similar current, known as the Labrador Current, flows down the eastern shores of North America as far as Cape Hatteras, where it dives under the Gulf Stream. Its temperature is very low (in the neighbourhood of 40° F.) and yet it is teeming with life. On one occasion Prof. W. Garstang when crossing the Atlantic eastwards tested the relative abundance of life in the Gulf Stream and Labrador Currents respectively by attaching a piece of bolting cloth to the bath tap of the steamer through which sea-water freshly pumped up was continuously passing. The bolting silk was afterwards rinsed in a bottle of formalin. After a few minutes passage of Labrador water, the contents of the bottle resembled a thick opaque emulsion, whereas after several hours passage of Gulf Stream water only a few grains were found in the bottle. The Labrador Current varies in width and when it invades the territory of the Gulf Stream it causes the death of the fish which live in the warmer water. On one notable occasion the 'file-fish' (*Lopholatilus*), which is allied to our sea-bass and is prized as a food-fish in America, was found floating dead in millions at the surface of the water. The passage from Gulf Stream to Labrador Current is a dramatic experience—which has happened to me on several occasions. Leaving the north of Ireland in the early autumn, one encounters the familiar type of mild stormy weather accompanied by drizzling rain, so unhappily associated with Irish summers. The bath water was exceedingly mild, as indeed is the sea-water encountered in bathing off the Irish coast in September. In a few hours the whole aspect of the sky changed. The weather might become dazzlingly clear or grey and foggy. The temperature fell and the bath-water became icy.

We have used for the warm water the term "so-called Gulf Stream" advisedly. The term 'Gulf Stream' in the narrower sense means the

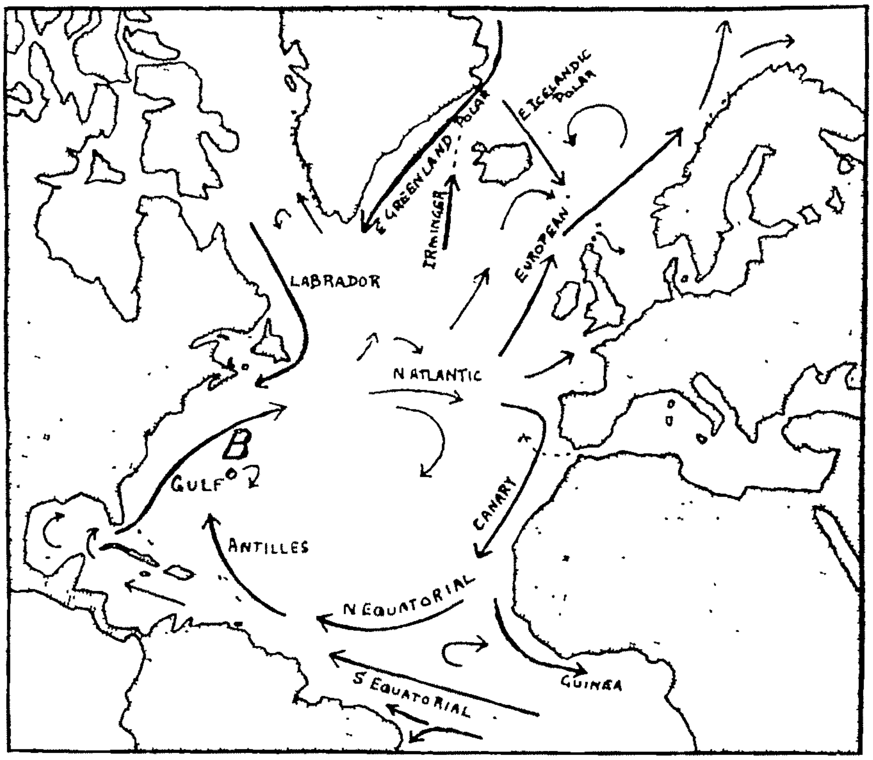

Fig. 1.
THE PRINCIPAL ATLANTIC CURRENTS. *B* = BERMUDA

water issuing from the Gulf of Mexico. But as a glance at the map (Fig. 1) will show, this current is joined by another termed the Antillean—which is fed by two currents, the North Equatorial and the South Equatorial, running west from the coast of Africa, and the water flowing through the Straits of Florida forms only one fifth of the total volume of the warm current. When this water reaches the coast of Africa, part of it turns south as the Canary Current which eventually joins the North Equatorial Current, so that it will be seen that in this way a huge vortex is constituted in the centre of which lies the calm water of the Sargasso Sea.

It is the merit of Prof. Garstang, who is a member of the Advisory Committee of the Development Commission on fishery matters, and of Dr. Robert Gurney who is a relative of the former Governor of Bermuda, to have brought before the notice of the Development Commission the suitability of the Bermuda Islands as a base for oceanographical research. The term 'islands' as applied to Bermuda is misleading. The gaps between the separate islands are so shallow that they are actually spanned by railway bridges, and the islands themselves are formed of nothing but wind-blown fragments of coral and other calcareous organisms cemented together by the deposit left by evaporating rain. It is clear that we have here the remains of a typical atoll without any trace of the peak which presumably once occupied the centre of the lagoon. Fifty miles north or south of Bermuda the enormous depth of 2,500 fathoms is reached, and Prof. Garstang has compared Bermuda to a lightship permanently moored in the centre of the ocean.

Turning again to the map, it will be seen that Bermuda (*B*) lies about 100 miles east of the Gulf Stream. Opposite it, west of the Stream on the coast of Massachusetts, is situated the Woods Hole Oceanographical Station, not to be confounded with the Woods Hole Biological Station, which is a totally distinct institution. The scheme of research planned by the Bermuda Committee is one to be carried out in the closest and most friendly co-operation with the Woods Hole Oceanographical Institute. The American corporation has a suitable research steamer, and the Bermuda Committee has appointed a sub-committee to draft plans for buying or building a suitable motor-boat. It is arranged that the two boats at suitable intervals shall penetrate about 100 miles into their respective sides of the Gulf Stream and take observations on the temperature and salinity at various depths. From these observations it can be shown that by an easy mathematical calculation the volume and velocity of the Gulf Stream can be computed and therefore the variation in volume over a series of years can be ascertained. In five years' time it is confidently anticipated that the correlation between these variations and the fluctuations in British fisheries will begin to emerge from obscurity, and the justification for continuing the research will become obvious.

As most people are aware, a Bermuda biological station has been in existence for about forty years. This is controlled by a Board of Governors of which until quite recently Prof. E. G. Conklin, of Princeton, the very distinguished American embryologist, was chairman. This corporation has in recent years endeavoured to widen its appeal by including in its number Dr. E. J. Allen, former director of the Marine Biological Association's laboratories at Plymouth, and the late Prof. J. H. Ashworth, of Edinburgh, and by appointing an Englishman, Dr. J. F. G. Wheeler, late of the *Discovery* Expedition, as director.

The investigations carried out at this station have been concerned solely with the fauna and flora of the warm water of the lagoon, as no boat was available which could safely be trusted in the turbulent oceanic water outside. The Bermuda Committee has entered into negotiations with the governors of the Bermuda station, and have been met in the most friendly spirit by that corporation. The Bermuda Committee has arranged to pay £250 a year for the rent of a portion of the Bermuda Biological Laboratory, including, of course, its equipment in tanks and water-supply. In addition, the Committee has agreed to pay half Dr. Wheeler's salary, as he, by his experience with the *Discovery* and by his local knowledge, is obviously the most suitable man to become director of the new Oceanographical Institute. The work of the Bermuda station is very intermittent and it is computed that he will be able to allot at least half his time to the Oceanographical Institute, and that indeed this work will extend the opportunities of ordinary biological workers at Bermuda, who may thus gain some acquaintance with the oceanic fauna.

The decision of the Government to support the Bermuda scheme was arrived at only on December 24 of last year and was immediately communicated by cable to the Bermuda corporation. The money is to be furnished in the first instance from the funds of the Ministry of Fisheries and thereafter by the Development Commission. As the whole scheme originated with the Commission, it may seem strange that the Commission did not at once assume the management of it. But the Commission was advised that its function was to criticize schemes put before it, not to initiate them, and the Royal Society was asked to nominate a committee to manage the new Institute. Of this Committee, Dr. Stanley Kemp, formerly leader of the *Discovery* Expedition, now one of its governors, and the new director of the Marine Biological Station at Plymouth, is secretary. The Committee met about two months ago and considered the grant of money necessary to carry out its plans; it applied for this grant to the Development Commission, which unanimously approved it. It then became possible to co-opt to the Committee two distinguished civil servants, namely, Mr. H. G. Maurice, assistant secretary of the Ministry of Agriculture and Fisheries, and Dr. E. S. Russell, chief scientific adviser on fishery matters. Needless to say, the assistance of these two members will be an invaluable addition to the powers of the Committee.

The staff to be appointed consists of Dr. Wheeler as director, a hydrologist, who will proceed to Woods Hole to be trained in the mathematical methods employed by that institute, and a director's assistant, who will be a naturalist.

It is perhaps vain to endeavour to lift the veil which shrouds the future, but it is to be remembered that the research work at Plymouth is really mainly oceanographical in character and with prophetic vision Dr. Kemp looks forward to the time when the Plymouth research will extend into mid-Atlantic and there meet in cordial co-operation with an eastward extension of the work of the Bermuda station.

Conduction of Electricity in Solids*

By Prof. N. F. Mott, F.R.S.

THE modern theory of the conduction of electricity in solids has already been applied to a large number of special problems; all that can be attempted here is a broad sketch of the fundamental ideas of the theory, together with an account of one or two of the most recent developments.

In the classical Drude theory, the conductivity of a metal depends on three quantities; namely, N, the number of free electrons per unit volume of the metal; v, their mean velocity, and l, their mean free path. Elementary considerations then give for the conductivity, σ,

$$\sigma = \tfrac{1}{2}Ne^2l/mv \qquad (1)$$

With certain slight modifications (in the quantum mechanical treatment v is actually the *maximum* electronic velocity) this formula may be transferred to the quantum mechanical treatment; the new theories are, however, important when we come to estimate N, l and v.

In monovalent metals we should expect that each atom would contribute just one to the total number of free electrons, so that N will be equal to the number of atoms per unit volume. For the alkali metals there is direct experimental evidence that this is the case. R. W. Wood[1] has shown that thin films of these metals deposited on glass are transparent to ultra-violet radiation below a certain wave-length, the transition from the opaque to the transparent region being rather sharp. Now as Zener[2] was the first to point out, one can apply to the reflection of light from a metal, provided that the absorption is neglected, the same formula as that used in the theory of the reflection of wireless waves from the upper atmosphere, namely,

$$n^2 = 1 - Ne^2/\pi m\nu^2 \qquad (2)$$

where n is the refractive index and ν the frequency of the radiation. n is real only for short wave-lengths; for long wave-lengths the right-hand side of (2) is negative and n imaginary, so that total reflection of the radiation takes place. From the observed long wave-length limit of the transparent region, therefore, N can be determined; it turns out to be quite near to the number of atoms per unit volume for each of the alkali metals. Formula (2) cannot be applied to other metals owing to the existence of characteristic absorption bands, such as the band at 3100 A. in silver.

As regards the mean velocity v of the metallic electrons, classical statistics, treating the electrons as a perfect gas, demand that their mean kinetic energy shall be $3kT/2$, corresponding to a velocity of $1{\cdot}2 \times 10^7$ cm./sec. at room temperature. The application of Fermi-Dirac statistics, first made to this problem by Sommerfeld[3], leads to the conclusion that the mean velocity has a very much greater value. The general ideas of the Fermi-Dirac statistics are most clearly seen by considering an idealized 'one-dimensional' metal, consisting of electrons free to move up and down a line of length L. We neglect first the interaction of the electrons, both with one another and with the atoms of the lattice. Now the velocity v of an electron is connected with its de Broglie wave-length λ by the well-known formula

$$\lambda = h/mv.$$

For an electron confined within a metal of length L, the de Broglie wave associated with the electron must have the form of a standing wave. The wave-length must therefore have one of the values

---

* Substance of a course of lectures delivered at the Royal Institution on January 19, 26 and February 2

$$\lambda = 2L/n, \qquad (3)$$

where n is an integer, and the energy of an electron will be

$$E = \tfrac{1}{2}mv^2 = n^2h^2/8mL^2, \qquad (4)$$

For values of L of the order of a centimetre, these values of the energy will be so close together as to be practically indistinguishable, so that to all intents and purposes the energy can take a continuous series of values. Nevertheless, our quantization of the energy is of importance for the following reason. According to the Pauli exclusion principle, not more than *two* electrons can be in any one quantized state. At the absolute zero of temperature, all the electrons will be in states of as low energy as possible; thus according to formula (3) two electrons only will have the lowest energy, corresponding to a wave-length $2L$. If the total number of electrons is N, the electrons will have all wave-lengths from $2L$ down to a minimum $4L/N$. With one electron per atom, this is equal to four times the interatomic distance a. The velocities thus have all values from practically zero up to a maximum $h/4ma$; with $a = 2 \times 10^{-8}$ cm. this corresponds to $v = 9 \times 10^8$ cm./sec., or an energy of 2·3 electron volts. Similar results are obtained when the motion of the electrons in three dimensions is taken into consideration, the maximum energy being

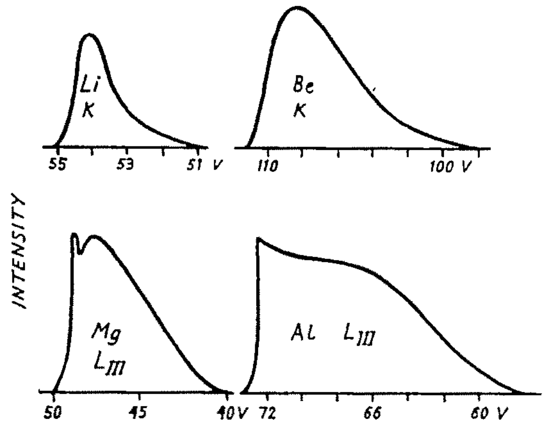

Fig. 1.

K AND L_{III}-EMISSION BANDS FOR LIGHT METALS; THE WAVE-LENGTHS ARE SHOWN IN ELECTRON VOLTS, ACCORDING TO THE EQUATION $eV = hc/\lambda$.

$$E_{\text{max.}} = \frac{h^2}{8m}\left(\frac{3N}{\pi\Omega}\right)^{2/3} \qquad (5)$$

where Ω is the volume of the metal.

At finite temperatures a few of the electrons will be excited into higher states (these electrons give a small contribution to the specific heat, linear in the temperature), but since kT is small compared with $E_{\text{max.}}$ up to the melting point, the change in the energy distribution of the electron is insignificant.

Experimental evidence that the conduction electrons have a series of energies lying in a range of several electron volts is provided by observations of the soft X-ray emission bands, of which those of O'Bryan and Skinner[4] (Fig. 1) are typical. The X-ray quantum is emitted through one of the conduction electrons making a transition to the K- or L-level; since the energies of the conduction electrons are distributed in a wide range, an emission band instead of an emission line is observed. The sharp cut-off at the high frequency limit will be noticed.

THE MEAN FREE PATH

Using values of N and v obtained in these ways, one can, by using formula (1), deduce the mean free path from the *observed* electrical conductivity; the following are some values for silver:

Temperature (degrees Kelvin)	273	76	4 2
Conductivity (ohm-cm. × 10^4) observed	6 8	36	(960)[5]
l (cm. × 10^{-4})	1·14	6	(168)

The very long mean free paths, far greater than the interatomic distance, will be noticed. These values, quite inexplicable according to the classical theory, are easily understood for a crystalline metal in terms of wave mechanics, as follows:

The model which we have used to derive the energies of the conduction electrons is highly artificial, neglecting as it does the interaction of the electrons with each other and with the ions. To remedy this, in all recent work each electron is treated as moving in the field of all the positive ions together with the *average* field of the electrons. The approximation is exactly that used by Hartree[6] in his calculation of the self-consistent fields in atoms. Thus, in a crystalline metal, if we use this model, we must think of the electrons as moving in a periodic field having the period of the lattice. In order to calculate the distance that an electron will move without being scattered we must apply the methods of wave mechanics, and picture a plane de Broglie wave moving through the metal with wave-length rather greater than the interatomic distance. We then obtain a result entirely at variance with classical ideas. Each metal ion scatters a wavelet, but since the metal is crystalline these wavelets build up a new plane wave front. There is therefore no resultant scattering of the wave. Hence, in a perfectly crystalline metal in which the ions are at rest in their positions of equilibrium, there is no scattering of the electrons and hence no resistance whatever.

Resistance in a pure metal arises from the fact that at any finite temperature the ions are not at rest in their positions of equilibrium, but are vibrating about them. The period of the atomic vibrations ($\sim 10^{-13}$ sec.) is very large compared with that of the de Broglie waves (10^{-16} sec.); the wave scattered by any displaced atom will therefore be slightly out of phase with that scattered by any other. A certain amount of incoherent scattering will take place. This incoherent scattering, and hence the resistance, will increase as the temperature is raised. Detailed calculations give good agreement with experiment both at high and low temperatures; though of course the model has proved totally unable to give an explanation of supraconductivity.

Although the periodic field of the crystal lattice does not lead to a finite mean free path, it has other effects; for example, the effective mass of an electron in a metal is found to be not exactly equal to that of a free electron. The further developments of the model, such as the explanation of the existence of insulators and semi-conductors by Wilson[7], cannot be discussed here.

Some attempts have recently been made to demonstrate these long mean free paths experimentally by measuring the resistivities of very thin wires[8], or of thin films deposited on glass[9]; obviously the mean free path cannot be greater than the thickness of the wire or film along which the current is flowing. We therefore expect the resistivity to increase for very small thicknesses. Such effects are in fact observed.

RESISTANCE OF ALLOYS

As first pointed out by Nordheim[10], the large increase in the resistance of metals due to foreign atoms in solid solution finds a ready explanation in terms of the theory. A dissolved atom taking the place of one of the atoms of the lattice will not in general scatter an electron wave of the same amplitude as the solvent atoms. If the amplitudes of the waves are denoted by A and B, the increase in the resistance will clearly be proportional to $(A - B)^2$. Since the scattering power of an atom depends on the field within it, we should expect the resistance to increase with the horizontal distance between the two elements in the periodic table. This was first pointed out as an empirical rule by Norbury[11]. More recently, Linde[12] has shown that the increase in the resistivity of copper or silver or gold due to one atomic per cent of any metal to the right of them in the periodic table is proportional to $(z - 1)^2$, where z is the number of electrons outside a closed shell (2 for zinc, 3 for gallium, 4 for germanium, 5 for arsenic). Such a simple rule is obviously susceptible of explanation in terms of this theory[13].

The explanation of the resistance given here does *not* depend on the strained state of the metal round the impurity atom. In general, the surrounding atoms will certainly be displaced from their mean positions, and this will give rise to an increase in the resistance, but the effect of this is probably small compared with the effect considered above.

The theory of the conduction of electricity in alloys is certainly capable of further development. One phenomenon to which it may possibly be applied is that of age hardening. This is generally believed to be due to the precipitation of very small crystals of solute metal from a supersaturated solid solution[4]. The resistance of an alloy during age hardening usually shows an initial increase, followed by a marked fall. The initial increase has been ascribed to strain, but this does not seem to be the only possible explanation. Since the wave-length of the electron waves is rather larger than the diameter of the solute atoms, one would expect the initial stages of the precipitation, in which small crystals of 20–30 atoms are formed, to increase the resistance. It is only when the crystals become large compared with the wave-length that any decrease in the resistance is to be expected.

If this explanation be correct, the phenomenon has a certain analogy with the passage of light through moist air. The water vapour molecules, being smaller than the wave-length of light, do not scatter it much. If, however, they condense into small drops of size comparable with the wave-length, a more or less opaque fog is formed. If they condense still further into rain drops, the atmosphere becomes again transparent.

CONDUCTION IN INSULATORS

Some light on the very complicated phenomena of photoconductivity has been shed by the recent theoretical researches of Landau[15], Frenkel[16] and others[17]. Their ideas will be illustrated most clearly by considering the alkali halide crystals, which have been investigated in great detail from the experimental side by Pohl and his school. The alkali halide crystals are built up of positive metal ions and negative halogen ions. The electrons in both these ions have the rare gas configuration, and do not make any contribution to the conductivity. If, however, an electron is added to one of the metal ions, one would expect that it would be able to jump quite easily from one metal ion to the next, and theoretical calculations[18] confirm this; such electrons ought to have a mobility of the same order of magnitude as the electrons in a metal.

If, however, a halide crystal is illuminated with ultra-violet light, a new absorption band is formed in the visible (the F-band), the rock salt thereby acquiring a yellow and silvine (potassium chloride) a blue colour. The F-band is generally recognized to be due to electrons attached to metal ions, and can be produced in other ways; for example, by heating in alkali vapour, so that positive ions and electrons diffuse into the crystal. The coloured crystal is, however, an insulator at low temperatures, and shows photoconductivity only when illuminated with wave-lengths in the F-band. It is therefore often stated that these electrons are located at internal surfaces or cracks, which might be expected to play some role in rendering the electron immobile[19]. The work of Landau shows, however, that this hypothesis is unnecessary; this will now be explained.

The large dielectric constant of polar crystals is partly due to an actual displacement of the positive and negative ions from their mean positions by an external field. The time taken to polarize the medium is of the order 10^{-13} sec., and since the electron jumps from atom to atom in a time comparable with 10^{-16} sec., it will not in general have time to polarize the medium as it goes. If, however, the electron remains in the neighbourhood of one metal ion for a sufficiently long time, it will polarize the surrounding medium, the positive ions moving into new positions of equilibrium nearer to, and negative ions farther from, the electron. The electrostatic field round the electron falls from $-e/r^2$ to $-e/\kappa r^2$, where κ is the dielectric constant. Therefore, in the field of the polarized medium, the potential energy of the electron is

$$V(r) = -\left(1-\frac{1}{\kappa}\right)\frac{e^2}{r}$$

In the 'potential hole' thus created, the electron will have a series of bound stationary states, similar to those for an electron in the field of a hydrogen atom, for which $V(r)$ is $-e^2/r$. The absorption band (F-band) corresponds to the removal of the electron from this potential hole and is thus analogous to the ionization of a hydrogen atom; the electron is then free to move through the crystal, and the potential hole disappears.

These trapped electrons have, according to Frenkel[16], a certain very small mobility, since the electron can jump from ion to ion and the surrounding ions move into displaced positions at the same time. Since by a well-known theorem of electrostatics a charged particle in a dielectric medium is repelled by any boundary of or hole in the medium, the most stable positions for trapped electrons will be as far as possible from any internal crack!

The theory of trapped electrons outlined here is quite general and can be applied to any polar solid; in future developments of the theories of the conduction of electricity in semi-conductors and insulators, it may prove of considerable importance.

Obituary Notices

Prof. A. R. Ling

ARTHUR ROBERT LING, whose death took place on May 14, owed his career as a research chemist to the inspiration of Prof. H. E. Armstrong, under whom he studied at the Finsbury Technical College in 1883 and thereabouts. He was encouraged to work on halogen derivatives of the nitrophenols, and he afterwards extended his investigations to similar derivatives of quinones, and in this began his long association with Julian Baker. The latter was continued when, as chemist to the London Beetroot Sugar Association, he carried out his routine work in the daytime, and in the evenings and at week-ends prosecuted with Baker his extensive investigations on the constitution of starch.

It is in the fields of starch and sugar chemistry and as an authority on brewing that Prof. Ling was best known. Ling's work during the decades preceding and succeeding the beginning of the century is recognized as being of sound character, and the interpretation of many of his results in the light of present-day knowledge and concepts adds materially to the known chemistry of starch and the mechanism of its degradation by diastase. It had, among other things, the important effect of preventing a hasty acceptance of erroneous views which were widely held at the beginning of the century.

After leaving the Beetroot Sugar Association, Ling practised as a consulting chemist, his special fields being the brewing and sugar industries. From 1895, that is, the time of its commencement, until 1920, he was editor of the *Journal of the Institute of Brewing*, and for many years technical editor of the *Brewers' Journal*, work for which he was most admirably suited and which he performed in a most competent manner. During the War period his work on the subject most dear to him, starch, was apparently almost at a standstill.

In 1920 Ling was appointed professor of brewing at the University of Birmingham, where he brought about the institution of an honours degree in biochemistry of fermentation. Now with better facilities than had hitherto been at his disposal, he was able to resume his work on starch. It was one of the great griefs of his declining years that this later work was incomplete. Nevertheless, more recent knowledge of the enzymes which were present in some of the preparations used by him at that time, now known to be composite, reveals that many of the results he obtained in conjunction with Nanji can be explained, although not in the way put forward at the time. In 1931 Ling retired from the chair at Birmingham, and generously bequeathed to the University the whole of his library of scientific books and journals.

To those who were privileged to know him well' Ling was a kind-hearted man, to whose encouragement many younger men owe a great deal. His enthusiasm for research was inspiring and his knowledge of the literature in his field amazing. In his domestic life he was dogged by ill fortune, serious illness and death being frequent visitors, culminating in the loss of his wife in 1935. Notwithstanding the latter and his own persistent ill health in the last two years, he maintained an active interest in scientific and technical work right up to the week of his death.

R. H. HOPKINS.

WE regret to announce the following deaths:

Prof. Alfred Adler, founder of the Society for Individual Psychology, originally called the Society for Free Analysis, at Vienna, on May 28, aged sixty-seven years.

Prof. Ladislas Natanson, formerly professor of physics in the Jagellonian University of Cracow, on February 26, aged seventy-three years.

Prof. A. G. Perkin, F.R.S., emeritus professor of colour chemistry and dyeing in the University of Leeds, on May 30, aged seventy-five years.

News and Views

Soviet Expedition to the North Pole

THE comprehensive Soviet scheme for the exploration and utilization of arctic territories has been carried another step forward by the institution of a polar research station within twelve miles of the North Pole. An aeroplane carrying Prof. O. Schmidt and several others left the meteorological station on Rudolf Island, Franz Josef Land, in lat. 81° 47′ N. on May 21 and flew over the Pole before landing on a convenient floe. A few days later three other aeroplanes arrived with materials for the hut, instruments, stores and fuel. The way between the station and Rudolf Island has been marked every thirty miles by bombs of dye-stuff. The hut, which is of metal, wood and rubber, is to be maintained for a year. It will be in wireless communication with Moscow, which will receive daily weather bulletins. The chief object of the enterprise is meteorological research, since only casual data have hitherto been obtained north of lat. 80° N. Such data will have a practical bearing on the proposed air route between the Soviet Union and the United States. The station is, of course, afloat and is reported to be drifting at the rate of about half a mile an hour. The direction is not stated: it may be rotary or more likely towards north-east Greenland. However, so long as the station remains in a high latitude, its purpose will be fulfilled, for its location actually at the Pole has more dramatic than practical value. A moving station will certainly facilitate hydrographical work. There is little likelihood of the floes disintegrating unless they drift into a much lower latitude or approach the area of ice pressure off northern Greenland.

The Thames Barrage Proposal

A DEBATE in the House of Lords on May 26 revived the publicity given about two years ago to a somewhat grandiose scheme for impounding the tidal area of the Thames above Woolwich by means of a dam, or barrage, across the river at that point. The scheme received a notable degree of attention at the time as it presented a number of attractive features, and was put forward with considerable plausibility of argument by its promoters, who have since been busily engaged in propaganda work through the agency of an organization, called the Thames Barrage Association. That a number of the promoters' contentions are true, or rather that they have a basis of fact, cannot be gainsaid by a fair-minded critic. There are undoubted defects to which, in some degree, the scheme might afford a remedy, principally, perhaps, in regard to mitigating the pollution, by tidal reflux of sewage effluent, of the river above the suggested dam. The promoters claim that the evil would be entirely eliminated; but this could scarcely be the case in view of the direct discharge, into the area proposed to be impounded, of sewage-laden tributaries. In all probability, there would be intensification of pollution immediately below the dam for lack of current movement.

THERE are, however, other serious counter arguments which cannot be disregarded or minimized. London, in addition to being a metropolis, is a great port, one of the largest in the world, and the requirements of shipping must therefore claim an important degree of consideration. As was pointed out by Lord

Ritchie, chairman of the Port of London Authority, in opposing the appointment of a Government commission of inquiry, which was the object of the debate, the substitution of half a dozen lock entrances at the barrage for an unimpeded fairway would mean obstruction to navigation and congestion of river traffic. On last year's figures, some 43,000 ships and 463,000 craft of various kinds would have to be locked through annually: the operation, he said, would be physically impossible. Moreover, the traffic is continually increasing. Other cogent reasons against entertaining the proposal were marshalled by the Earl of Erne, speaking for the Government, who explained the antipathetic views of the Ministries of Transport and Health and of the Board of Trade. In the issue of NATURE of December 7, 1935, we said that "an enterprise of this magnitude cannot be embarked upon without a considerable degree of risk to important interests, however propitious the general circumstances may appear to be" and, in view of the announcement that the estimated outlay is 4½ millions sterling, the need for a cautious attitude is greatly increased. Indeed, the objections already put forward are of so weighty a character that the trouble and expense of a public inquiry were considered unjustified by the Government and, under protest, the motion was withdrawn.

A Suggested Botanic Garden in South Florida

THE attempts to raise tropical plants under the extremely artificial conditions imposed by a temperate climate limits greatly the scope and usefulness of botanic gardens in the latitude of North America and Europe. The suggestion, therefore, which has been put forward, to found a tropical botanic garden in the United States, is warmly welcomed; for this will, in a way, bring the tropics within the reach of American botanists and plant breeders ("An Argument for a Botanical Garden in South Florida, to be called the Fairchild Botanical Garden", by Marjory S. Douglas. Kells Press, Coral Gables, Florida). The only possible site appears to be that suggested, which is in a frost-free area in the extreme south of Florida. This is close to Chapman Field, where the United States Department of Agriculture has its Plant Introduction Garden, with which the name of David Fairchild is so closely associated. Here are grown tropical plant introductions for the needs of the Department of Agriculture. It serves a very useful purpose in this respect, but it differs from a botanic garden in that it does not offer a permanent home to tropical trees and plants. It is strictly utilitarian and is not laid out with that æsthetic taste which one associates with botanic gardens and which has so large an educational effect on the visiting public.

THOUGH the United States are fortunate in having a site for a tropical garden within their boundaries, and therefore of easy access to those who wish to visit it, the establishment of such a garden will be a costly undertaking. The soil of this region is extremely shallow, and much of it exists in crevices in the soft limestone which is often exposed on the surface. The principal agricultural industry in this area is fruit growing, and extensive orchards of mango, avocado and citrus have been established. Formerly, planting holes for the trees were blasted out of the soft rock, but it was found that the roots were strictly confined to the filled-in excavation thus formed. In recent years, soils have been made by 'scarifying' the surface with very heavy engine-drawn cultivators. The exposed soil with the limestone rubble is then collected into low, wide ridges along the top of which the trees are planted. It is found that a more extensive root system is thus formed, and the trees suffer much less from violent wind storms which occasionally visit this coast. Such calcareous soils are usually associated with the dry tropics, and it is possible that many species from such regions may thrive here, but in the humid tropics, which are so rich in their floras, the soils are generally acid and contain very little lime and, though many species of palms with their peculiar root system may be able to adapt themselves to local soil conditions, it is a different matter for many evergreen, broad-leaved species. To obtain the desired luxuriant tropical growth it may, therefore, be necessary to transport suitable soils in large quantities in which to grow such trees and plants, and this—if it proves to be necessary on an extensive scale—requires generous contributions towards the funds for founding these tropical botanic gardens.

Central Asiatic Gold Mines of the Bronze Age

THE sources from which prehistoric peoples obtained their minerals and other raw materials of industry afford valuable clues to their intercourse and cultural and economic contacts. A new source of gold in Central Asia is reported in the announcement of a discovery of prehistoric workings at Kazakhstan by a Russian expedition sent out by the Soviet Government (Soviet Union Year Book Press Service). The mines had been worked by a large number of workmen who used some implements of bronze, but for the most part of stone and the bones of animals. There were no traces of iron. Near the shafts were primitive ore-crushing plants, consisting of stone slabs and hammers. Two skeletons of these bronze age miners were found, who had met their death by a fall of the roof. On one of the skeletons was a necklace of glass and clay beads and in one hand was a bronze chisel and in the other a stone hammer. They were not Mongolian, as was indicated by their skulls. The mines were 0·75 m. wide and 20–25 m. deep. They were connected by underground passages 100–150 m. long. These passages had natural ventilation, and for illumination it is probable that fat in shallow bowls was employed. Some of these bowls have been found. Stone cross pieces were used as props. Polished slabs and triangles of stone have been found which appear to have been used on the steppes of Kazakhstan as sign-posts to guide caravans on their way to the mines. The slabs were orientated and polished on the eastern side. The Soviet Government is sending out another expedition this year to explore the mines further, and to work the ore which was left unextracted by the ancient miners.

Atmospheric Pollution

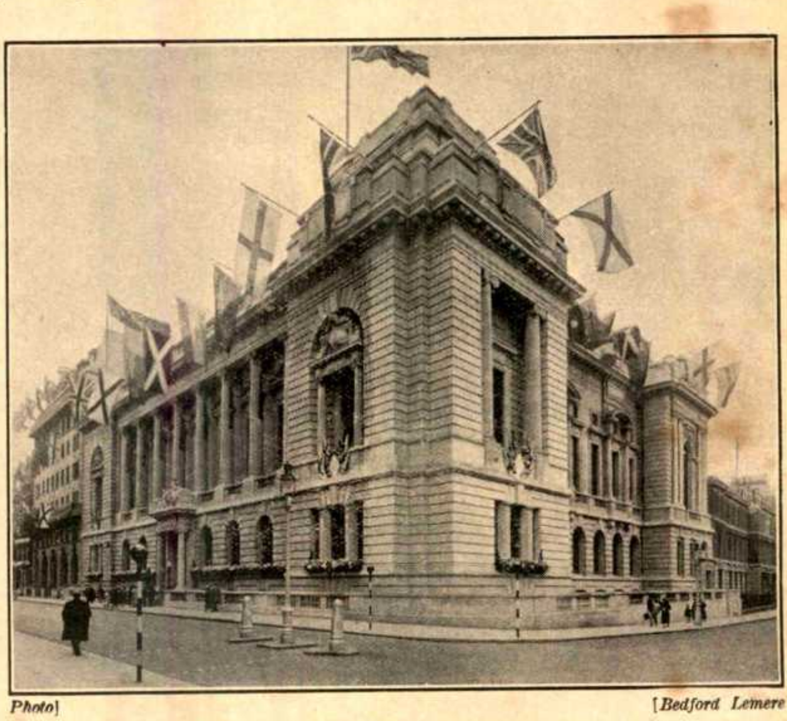
THIRTY-EIGHT representatives of local authorities and other organizations co-operating with the Department of Scientific and Industrial Research met on May 31 at the offices of the Department in the usual half-yearly conference. Dr. G. M. B. Dobson, chairman of the Atmospheric Pollution Research Committee, presented, as usual, a report on the progress of the investigations carried out under the Committee. Systematic observations in connexion with the intensive survey of the pollution in and around the City of Leicester were begun on April 1. During the preceding four months, the survey staff were installing different standard measuring apparatus at twelve sites. The decision of the authorities at Leicester to equip and maintain a station for regular meteorological observations was greatly welcomed. The Conference also recorded its appreciation of the valuable assistance given by the public analysts of Glasgow, Hull and Sheffield, in an investigation of the possibility of combining a dust filter with apparatus for the determination volumetrically of sulphur dioxide in the atmosphere. A report was submitted through the Medical Officer of Health for Leeds on the analysis of dust samples collected in Leeds, Halifax and Huddersfield. The Conference endorsed a proposal made by the Research Committee that a meeting should be convened of public analysts and others who are directly responsible for making observations on behalf of co-operating bodies, to discuss technical problems and to interchange ideas on the measurement of atmospheric pollution. Mr. Brownhill Smith retired from the chairmanship of the Conference, having served for the maximum period of three consecutive years. Alderman David Adams, a representative of Newcastle-upon-Tyne, was elected chairman for the ensuing year.

Study of Bird-Migration

The British Trust for Ornithology has accepted responsibility for the future conduct of the principal scheme in Great Britain for the study of migration and other aspects of bird-life by the ringing method. This scheme was instituted in 1909 by Mr. H. F. Witherby, editor of *British Birds*, and has been maintained with the co-operation of readers of that journal. More than half a million birds have been marked to date, and the recoveries of a proportion of these have already added greatly to knowledge of the subject. Important facilities for the work have at the same time been granted by the Trustees of the British Museum (Natural History), who are providing accommodation for the headquarters of the scheme in the Bird Room at South Kensington and permitting the Museum's address to be used. Rings will in future be inscribed "British Museum Nat. Hist. London", instead of "Witherby High Holborn London", with an individual identification number in addition as before. The scheme will now be directed by a special Bird-Ringing Committee, constituted as follows: Dr. A. Landsborough Thomson (chairman); Mr. A. W. Boyd; Mr. A. B. Duncan; Mr. P. A. D. Hollom; the Earl of Ilchester; the Earl of Mansfield; Mr. H. F. Witherby; and Miss E. P. Leach (hon. secretary). The headquarters' work will be in the hands of Miss Leach, who has had much experience of it as Mr. Witherby's collaborator in recent years. *British Birds* will continue to be the medium for publishing results.

Institution of Civil Engineers

WHEN the foundation stone of the present building of the Institution of Civil Engineers was laid in 1910 by the late Sir James Charles Inglis, then president of the Institution, the north-west corner could not be completed owing to the existence of a lease covering offices flanking that corner of the site. The demolition of the offices was, for various reasons, deferred until 1936; but the corner, with the consequent internal modifications in the library and reading-room, is now practically completed (Fig. 1), and Princes Street, which is to be known as Rennie Street from July 1, 1937, has also been widened to



Photo] [*Bedford Lemere*

Fig. 1

COMPLETED BUILDING OF THE INSTITUTION OF CIVIL ENGINEERS its full width. The rebuilding of the north-west corner has allowed of an extension to the main library, in addition to extensions to the rooms on the other floors, and advantage is being taken of this extension to house, at the west end of the main library, the original collection of books, etc., presented by Thomas Telford to the Institution in 1820, which formed the nucleus of the existing library, now containing more than 62,000 volumes.

Television Exhibition

PARTLY with the view of demonstrating that television has now emerged from the experimental stage, partly to illustrate the general principles which underlie the modern technique, and partly to foster the widest possible appreciation of television as a home entertainment, a special exhibition has been organized by the Science Museum, South Kensington, in co-operation with the British Broadcasting Corporation and the leading manufacturers. The exhibition will be opened by Lord Selsdon, chairman of the Television Advisory Committee, on June 10. The exhibition incorporates a historic section dealing briefly with early proposals for television, and a number of exhibits describe the developments of the past ten years. There is a working demonstration of the low-definition television which was broadcast by the Baird process a few years ago, there are demonstrations on modern cathode ray receivers supplied by the various manufacturers, and a demonstration of large-screen television by a mechanical-optical process. In order that these demonstrations can be given when there is no B.B.C. transmission available, a local transmitter has been installed which will provide programmes from cinema films. In connexion with the exhibition a handbook has been compiled by Mr. G. R. M. Garratt, assisted by members of the Exhibition Committee. Copies will be on sale at the Science Museum, or may be obtained from the publishers, H.M. Stationery Office, price 6*d.* (by post 7*d.*).

The Royal Society of Arts

FEW societies have done more to stimulate the arts and industries of the British Empire than the Royal Society of Arts, which during the last few days has had on exhibition, for the benefit of overseas visitors, a series of documents and objects illustrating its achievements since its foundation in 1754. Before the modern practice of holding frequent meetings to hear papers and lectures, the Society instituted awards for improvements in science, art and manufacture; and many of the objects exhibited illustrate the work of some of the Society's medalists. Hanging on one side of the room in which the exhibition was arranged was the first geological map of Great Britain prepared by William Smith. The map was published in 1815, Smith being assisted by a grant of £50. On the other side of the room were a model of Abraham Darly's iron bridge of 1788 (happily still standing); a model of Greathead's lifeboat and Bell's lifeline-throwing mortar for ships, for which medals were awarded. On another stand were samples of coco-nut oil, cinnamon, silk, tea, nutmegs, cloves, mace, wool and indigo from the Colonies, all representing products the cultivation of which has been stimulated by the Society. In addition to these and similar objects, were many books, prints and letters recalling the history of the Society and its never-ceasing activity.

Institute of Physics

THE annual report for the year 1936 of the Institute of Physics presented at the annual general meeting held on May 26 shows that the total membership has continued to increase in a very satisfactory way. The membership at the end of the year was 902. An informal discussion on the training of industrial physicists was held on February 11, 1936, at which appointed representatives of nearly every university and college in Great Britain and Ireland, of firms employing physicists and of research associations and Government establishments were present. As a direct result of this discussion, a scheme was inaugurated whereby registered students of the Institute are enabled to gain first-hand experience of industrial research and development work in physics during their vacations. The report records that in its first year this scheme proved most successful. The fifth conference of Australian physicists and astronomers was convened by the Australian Branch of the Institute and was held in Sydney on May 25–28, 1936. A London and Home Counties Branch of the Institute was founded in November. The general improvement in industry is reflected by the report of a great increase in the activities of the appointments register and panel of consulting physicists maintained by the Institute. The following officers have been elected to take office on October 1: *President*, Mr. C. C. Paterson; *Vice-President*, Prof. W. Makower; *Honorary Treasurer*, Major C. E. S. Phillips; *Honorary Secretary*, Prof. J. A. Crowther; *New Members of the Board*, Prof. J. Chadwick and Mr. D. C. Gall.

Maynard Ganga Ram Prizes

IN 1925, the late Sir Ganga Ram, presented to the Punjab Government a sum of Rs. 25,000 for the endowment of a prize of the value of Rs. 3,000 to be called the Maynard Ganga Ram prize and to be awarded every three years, for a discovery, invention, or a new practical method which will tend to increase agricultural production in the Punjab on a paying basis. The competition is open to all. The first award, due in 1929, was made in 1931 to Dr. C. A. Barber, late Imperial sugar expert, for his fundamental discoveries which resulted in the production of Coimbatore sugar-cane. During the last five years, no further awards have been made owing to lack of suitable entries. The 1932 award has now been made to T. A. Miller Brownlie, lately agricultural engineer to the Government of Punjab, for his invention of a slip strainer suitable for water augmentation supplies derived from bores sunk in open wells. This strainer has the particular merit that it is not affected by alkaline sub-soil water—a defect from which many of the earlier metal strainers suffer. By its use, owners of well-irrigated lands can increase the output of water from their wells. The 1935 prize has been awarded to R. S. L. Jai Chand Luthra, professor of botany, Punjab Agricultural College, Lyallpur, for his new method of treating wheat seed against the fungal disease called loose smut. The wheat seed to be treated is merely soaked in water at ordinary temperature for four hours during the morning of a day in summer. Thereafter the soaked grain is spread in the sunshine until it is thoroughly dried. Experience has shown that this treatment is effective in controlling the disease without damaging the germinating power of the seed. Entries for the next award should reach the Director of Agriculture, Punjab, Lahore, on or before December 31, 1938.

Aquarium Notes

THE *Aquarist and Pond-Keeper* of March–April 1937 (**7**, No. 7) contains a good article (to be continued) on the freshwater sunfishes (family Centrarchidæ) by A. Fraser Brunner. These fishes are natives of North American freshwaters, their nearest relatives being the perches. A key to all the species is given with notes, and a double-page illustration together with a coloured plate comprises most of the species which can be kept in aquaria. Among other interesting contributions is one entitled "The Ways of the Natterjack" by Eric Hardy. The author states that he finds no difficulty in obtaining specimens in early spring and late summer on the brackish slacks of the west Lancashire dunes below Southport, and others may be found at the Solway marshes, in the Prestatyn district of the Conway estuary, North Wales, at Hilbre Island in the Dee Estuary and on the Leasowe marshes of the West Cheshire coast. He has kept this toad successfully in indoor aquaria.

Birth-rate in the United States

THE birth-rate in the United States, based on returns from thirty-four of the forty-eight States and covering only the first nine months of 1936, was the lowest on record, according to a provisional report recently issued by the Metropolitan Life Insurance Company (*Med. Rec.*, Feb. 17). The death-rate was slightly higher than that of any year within the last five, so that the natural excess of the birth-rate over the death-rate fell to a minimum of about 5 per 1,000.

A Heidelberg Correction

WITH reference to the article in our issue of January 16, 1937, "University of Heidelberg and New Conceptions of Science", Dr. E. Wolf, Privatdozent of the University of Heidelberg, writes to us from the Biological Laboratories at Harvard University under date April 20, as follows: "I had already left Heidelberg in Fall of 1931 with the consent of the Minister of Education and that of the Faculty of Science, to accept an invitation from Harvard University. Since then I have been on a leave of absence from Heidelberg and I can assure you that I regard it always an honour to be a member of the Faculty of the University of Heidelberg".

Göttingen and the Massachusetts Institute

IN response to requests for information on the extent of the Institute's participation in the celebration on June 30 of the two hundredth anniversary of the founding of the University of Göttingen, the Massachusetts Institute of Technology has issued the following statement: "Although the Massachusetts Institute of Technology will not send an official delegate from Cambridge to attend the celebration of the two hundredth anniversary of the founding of the University of Göttingen, the rector of the university has been notified that Werner T. Schuarte, a technology alumnus of the class of 1914, who lives in Germany, will represent the Institute as an academic courtesy to a university which during the past two centuries achieved world-wide renown through distinguished scholarship and notable contributions to the advancement of scientific knowledge. This action is not intended to condone changes in or restrictions placed upon German universities in recent years."

Canadian National Research Council Scholarships

WITH the view of encouraging postgraduate training in scientific research, chiefly in the graduate schools of Canadian universities, the National Research Council has awarded forty-seven scholarships for the year 1937–38. These include three fellowships of 700 dollars each, twelve studentships of 600 dollars and twenty-seven bursaries of 500 dollars, all of which will be held in departments of science at the universities. Five other scholarships, tenable in the National Research Laboratories at Ottawa, will enable the holders, all of whom have already done postgraduate research at the universities, to gain experience in the field of industrial research before engaging in commercial work. The awards show that chemistry in its various branches heads the list with twenty-five, physics comes next with twelve, followed by four in biology, two in genetics, and one each in botany, geology, mathematics and mechanical engineering. Applications were received from graduates of eighteen Canadian universities, and awards have been made which will enable the holders to work in the Universities of Dalhousie, Laval, McGill, Montreal, Queen's, Toronto, Western Ontario and Saskatchewan.

Congress of French Physiologists

THE eleventh Congress of French Physiologists will be held on June 7–9 at the Paris Faculty of Medicine under the presidency of Prof. Cardot, of the Lyons Faculty of Science. The principal subjects for discussion will be trophic sensibility, introduced by A. Pi Suner, professor of physiology at Barcelona; comparison of histological and biochemical data in ossification, introduced by Profs. Policard, of the Lyons Faculty of Medicine, and Roche, of the Faculty of Medicine at Marseilles, and exploration of organic functions by the electrical manifestations of their activity, by Prof. Ryart of the University of Brussels. Further information can be obtained from M. R. Gayet, Laboratoire de Physiologie Pathologique, 1 rue Lacretelle, Paris.

British Waterworks Association

THE twenty-sixth annual general meeting of the British Waterworks Association will be held in London on June 22–26 under the presidency of Sir William Prescott. The following papers will be read and discussed: "The Inland Water Survey", by R. G. Hetherington; "Present-day Aspects of the Purification of the London Water Supply", by Lieut.-Colonel C. H. H. Harold; "The Work of the Freshwater Biological Association of the British Empire", by Prof. P. A. Buxton, of the London School of Hygiene and Tropical Medicine; "The Present Aspects of the Rivers Pollution Prevention Problem", by H. F. Atter. Further information can be obtained from the Secretary, British Waterworks Association Office, Grand Buildings, Trafalgar Square, London, W.C.2.

Agricultural Abstracts

UNDER a recent agreement between the Central Agricultural and Scientific Bibliography and the Bureau of Chemical Abstracts (Chemical Society and Society of Chemical Industry) it has been arranged that the staff of abstractors engaged on abstracting work for that Bureau will be invited to act as abstractors in the interests of the C.A.S.B., to the extent that while engaged on their ordinary work they will also prepare a comprehensive list of those articles and papers published in the same journals, which should in their opinion be specially useful to subscribers to Section 1 (Agriculture and Allied Industries) of the C.A.S.B. The scheme has been in operation since January 1, 1937, and it is proposed to issue shortly the first bibliography in this series to all subscribers to the C.A.S.B. Further information can be obtained from W. P. Dreaper, Hon. Secretary, C.A.S.B., Science Museum Library, South Kensington, London, S.W.7.

Announcements

THE Albert Medal for 1937 of the Royal Society of Arts has been awarded to Lord Nuffield, "for services to Industry, Transport and Medical Science". The Medal was instituted in 1862 as a memorial of H.R.H. the Prince Consort, for eighteen years president of the Society, and is awarded annually for "distinguished merit in promoting Arts, Manufactures, or Commerce".

DR. MARCUS FRANCIS has been appointed director of research to the British Pottery Manufacturers' Federation. The Federation, in conjunction with the Department of Scientific and Industrial Research, is to establish a new research station in the extension of the North Staffordshire Technical College, Stoke-on-Trent. Dr. Francis is at present on the technical staff of the Munitions Technical Planning Establishment.

THE annual general meeting of the Research Defence Society will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, on June 15 at 3 p.m., when the eleventh Stephen Paget Memorial Lecture will be delivered by Prof. G. Grey Turner. The subject of Prof. Turner's lecture will be "What Research Owes to the Paget Tradition".

THE Emil Chr. Hansen Gold Medal and a prize of 3,000 Danish crowns has been awarded to Prof. Aurelio Quintanilha, professor of botany in the University of Coimbra, for his valuable investigations on sex in the Hymenomycetes.

THE forty-eighth annual conference of the Museums Association will be held at Newcastle-upon-Tyne on July 5–9, under the presidency of C. Squire. Further information can be obtained from the Secretary, E. W. Wignall, Chaucer House, Malet Place, London, W.C.1.

THE annual summer meeting of the Association of Technical Institutions will be held at Blackpool on June 25–26 under the presidency of the Right Hon. Lord Kennet. Further information can be obtained from Dr. H. Schofield, Loughborough College, Loughborough, Leicestershire.

THE German Rontgen Society has recently founded a Röntgen Institute at Munich containing a museum and library. Publications should be sent to Ottostrasse 5, München.

THE second World Congress on Mental Hygiene will be held in Paris on July 19–23 under the auspices of the French League for Mental Hygiene. Further information can be obtained from the Secretary of the National Council for Mental Hygiene, 76 Chandos House, Palmer Street, London, S.W.1.

THE third Annual Conference of the National Federation of Personal Health Associations will be held at the British Medical Association's House, Tavistock Square, W.C.1, on June 24 at 2.45 p.m. The chief subjects for discussion will be the Government campaign to promote the physical fitness of the people and the part to be played by local authorities and individuals in co-operating with the National Advisory Council to ensure the success of the campaign.

WITH reference to the paragraph in NATURE of May 29 (p. 915) including the names of new officers of the Linnean Society, the Assistant Secretary informs us that, "owing to an error on our part, the name of Mr. Fred Howarth as a new member of council was omitted from the notice sent". Five new members of Council are elected annually.

ERRATUM. The X-ray photographs of nitrided steel reproduced as Fig. 6 in Sir William Bragg's article "Recent Crystallography" printed in NATURE of May 29 were incorrectly ascribed to Dr. G. Shearer. The photographs are due to Mr. W. A. Wood, of the National Physical Laboratory.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 969.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Dry Crossings of the Nile

ATTENTION has been directed on page 351 of NATURE of February 27, 1937, to a natural bridge "so strong that it bears the elephant from one bank to another", near Nimule, which is situated at the point where the Albert Nile, as it is commonly called to-day, becomes the Bahr el Jebel. It is clear that Dr. Hurst finds difficulty in believing in any such phenomenon, for in his review of May H. Lindsay's translation, the "Life Story of a River", from Emil Ludwig's work, he says: "Nobody else has ever reported this bridge." This is not so.

So far as I can discover, I was the first European to see and describe a natural bridge, or dry crossing, near this point, or to know of its existence; and it seems clear that Emil Ludwig obtained his information from a short illustrated account that I wrote of it. I first saw this dry crossing from the air in 1930 when I supposed it to be a temporary blockage by sudd which had been burnt; and three years later I crossed it on foot. It is or was situated, for I hear that it is slowly breaking up, at a point about seven miles below the Folar rapids.

The following is taken from the account above referred to[1]:—

"The dry crossing is a blockage some 1,200 feet in length and about 370 feet across and occupies the entire width of the Nile at that place. Its surface consists of soft soil with a very high percentage of vegetable matter, supporting an herbaceous land flora, but no papyrus. It is edged on its upstream side with a broken line of tree trunks (for the most part boles of palms) leaning steeply upstream and thus recalling a raked stockade. Apart from being soft and powdery the ground is unyielding, except near the right bank where it responds to the foot as a mattress does on a spring bed; but there is so little danger of going through into the water below that elephants cross over the surface, as some fresh spoor clearly indicated".

"About 570 feet upstream of the usual path over the crossing extending for a length of seventy-five feet an oily-looking pool breaks the dry surface, and from time to time ugly swirls appear upon it, and immediately downstream of the path is a much smaller pool of a similar kind, while in line with this at the downstream end of the blockage there is an exposed channel along which water can be seen swiftly flowing. It would appear that the main course of the Nile under the blockage is by the right bank." The flow of the Nile in this part of its course is powerful.

A similar dry crossing has been described by Sir Samuel Baker who, on page 455 of his "Albert Nyanza Basin of the Nile," 1892, says: ". . . we arrived at the junction of the Bahr el Gazal, and turning sharp to the east, we looked forward to arriving at the extraordinary obstruction that since our passage in 1863 had dammed the White Nile."

"There was considerable danger in the descent of the river upon nearing this peculiar dam, as the stream plunged below it by a subterranean channel with a rush like a cataract. A large diahbiah laden with ivory had been carried beneath the dam on her descent from Gondokoro in the previous year, and had never been seen afterwards"

E. J. WAYLAND.

Geological Survey,
Entebbe, Uganda.
April 7.

[1] Wayland, E. J., "A Dry Crossing of the Nile", *Uganda Journal*, 1, No. 1, 68–69 (1934). Another note of interest in the present connexion is the following Pitman, C. R. S., "A Dry Crossing of the Nile and its possible Influence on the Distribution of Mammalian Species", *Uganda Journal*, 2, No. 1, 86–89.

I HAVE read with interest Dr. Wayland's letter on the subject of a natural bridge over the Nile some eleven miles below Nimule. Unfortunately, I had not seen his note in the *Uganda Journal* when I wrote my review of Dr. Ludwig's book or I should have realized that "A natural bridge has grown at Nimule, such as hardly another river on earth possesses in this form, consisting of rank water plants, so strong that it bears the elephant from one bank to the other, and so powerfully rooted that when floods have destroyed it, it closes up again of itself" was merely an inaccurate way of describing a sudd block, and did not relate to some entirely new phenomenon of vegetative growth.

So far as I know, "sudds" (the word "sudd" is Arabic for a blockage) have not previously been reported on the stretch of river between Nimule and Rejaf, where the rapid stream is unfavourable to their formation, but farther north in the area known as the Sudd Region, where the Bahr el Jebel flows through swamp, they were of common occurrence in the last century. One of the first pieces of work undertaken on the Nile after the reoccupation of the Sudan was the removal of these blocks, and this was successfully accomplished in the early years of the present century. Since then, owing to the regular navigation of the Bahr el Jebel by steamers, blocks have rarely occurred, as it has been possible to remove obstructions before they became consolidated.

A full account of the formation and history of these sudds on the lower Bahr el Jebel was given by Sir Henry Lyons[1] and a shorter account by Phillips and myself[2].

Similar blocks have occurred on the Victoria Nile at its exit from Lake Kioga, on the Pibor, and on the Bahr el Ghazal where in 1880 the steamer of Gessi, one of Gordon's officers, was completely shut in for some weeks, and many of his company died.

The blocks which occurred on the lower Bahr el Jebel were composed mainly of papyrus, reeds and um soof, large masses of which with earth clinging to their roots were sometimes torn loose by the combination of strong winds and a rising river and found their way into the main stream, where they were arrested at a sharp bend or a narrow part of the channel. As these masses were sometimes acres in extent, the channel became blocked by floating vegetation, and so its section was reduced while the velocity of the water below the mass increased. Fresh vegetation as it arrived was sucked under the old and caught in the narrowing section, so that the block increased and became consolidated by the heading up of the water behind it. In this swampy region the water sometimes found another channel, but sometimes the block burst under the pressure of the water.

The block to which Dr. Wayland directs attention was no doubt formed from vegetation uprooted on the swampy reach above Nimule in the same way as has just been described. The conditions, however, are different inasmuch as the river at the block is in a narrow rocky valley and not in swamp, and the velocity of the water is greater than on the lower Bahr el Jebel. Some interesting points mentioned in the article in the *Uganda Journal* are, that natives say that the blockage is not permanent but that there have been several at the same spot each lasting for a few years, and that their formation is in no way related to the height of the river.

In 1924 I was at what appears to be the spot described by Dr. Wayland, and at that time a block must have been just beginning to form, for at a point where the river narrowed suddenly there was an accumulation of floating dead vegetation, mostly um soof, covering the whole width of the river and extending for perhaps thirty yards upstream. It was, however, not at all consolidated nor was it a serious obstruction to the river.

The Bahr el Jebel draws the greater part of its water from Lake Albert, and in the dry season only changes its level slowly; but in the rainy season from April to October it is liable to rises and falls due to torrential tributaries entering it between Lake Albert and Nimule.

I would suggest that, as in the case of the lower Bahr el Jebel, a rise of the river accompanied by strong winds occasionally detaches a mass of vegetation large enough to form a block at the constriction, and that the block increases and consolidates as I have already described. As there is no possibility of the river opening a new channel, the block can only be removed by bursting. This would probably take place when the river rose considerably; perhaps also after a time the barrier is weakened by the rotting of the lower layers of vegetation. Thus both the formation and destruction of the sudd would depend to some extent on rises of the river and not on its actual level, in accordance with native report.

In the past it has been suggested that the site of a dam to convert Lake Albert into a reservoir might be at Nimule. One of the objections raised against this choice of a site was the danger of vegetation accumulating above the dam and blocking the sluices. Weight is added to this objection by the fact that a sudd can form at present near the proposed site.

I am sorry to have doubted Dr. Ludwig on a point which had a sound foundation, but my doubt has had the good result of directing attention to Dr. Wayland's description of a very interesting phenomenon.

As Imperial Airways have a regular service passing near the site of the block, it might perhaps be possible for their pilots to keep notes of its state, so that the conditions which lead to its formation and destruction may be investigated.

H. E. HURST.

Physical Department,
Cairo.

Radioactivity Produced by Gamma Rays and Neutrons of High Energy

WHEN lithium is bombarded by protons of energy of about 450 kV., gamma rays of about $17 \cdot 5 \times 10^6$ eV. energy are emitted. Recently Bothe and Gentner[1] have observed that these gamma rays can produce radioactivity in many elements. In all the cases reported, the primary process probably consists in the emission of photo-neutrons. In six cases they have observed the formation of new radioactive isotopes. These are gallium (60 min.), bromine (5 min.), silver (24 min.), indium (1 min.), antimony (13 min.) and tantalum (14 min.).

We have repeated some of their experiments with similar results using lithium metal targets bombarded by magnetically separated protons of about 520 kV. and 10–20 μ amp. ion currents as gamma ray source. We have also observed a weak 'photo-radioactivity' in oxygen with a half-period of about 2 min. This is probably due to the formation of the known radioactive isotope ^{15}O (2·1 min.) according to the reaction:

$$^{16}O + h\nu \rightarrow {}^{15}O + {}^{1}n.$$

The threshold energy for removal of a neutron from a stable isotope is presumably well below $17 \cdot 5 \times 10^6$ eV. for most elements. We have therefore attempted to produce the new radioactive isotopes by means of gamma rays and also by neutrons of energy smaller than that of the lithium gamma rays. Radioactivity produced by 'neutron loss' (as opposed to 'neutron capture') was first observed by Heyn[2] in copper bombarded by the neutrons from lithium + deuterons.

We were able to produce five of the new radioactive isotopes reported by Bothe and Gentner, by using the neutrons of lithium + deuterons and boron + deuterons (energy $\leqslant 13 \cdot 5 \times 10^6$ eV.). For a voltage of about 520 kV. and equal ion current (deuterons or protons) the yield in radioactivity was usually much higher in the case of neutrons than in the case of lithium gamma rays. We were unable to detect any radioactivity with the gamma rays from boron + protons (energy $\leqslant 14 \times 10^6$ eV.) and beryllium + protons (energy $\leqslant 6 \cdot 5 \times 10^6$ eV.). Our results concerning radioactive isotopes which cannot be obtained by neutron capture are summarized in the accompanying table.

As antimony has only one known slow neutron period but two isotopes, we specially verified that the 13 min. period cannot be produced by slow neutrons, the upper limit for its intensity being $1/10^5$ of the activity produced by slow neutrons in indium (54 min.). It seems therefore very likely that the 13 min. period is due to ^{120}Sb, and not to ^{122}Sb.

After bombarding with neutrons of lithium + deuterons we sometimes noticed a short-period radioactivity which we finally found to be due to oxygen. This element can be activated very strongly. Its activity decays with a period of 8 seconds, which is apparently identical with that observed in fluorine bombarded by fast neutrons, and long presumed to be due to ^{16}N. We may therefore account for this period by the reaction :

$$^{16}_{8}\text{O} + ^{1}_{0}n \rightarrow ^{16}_{7}\text{N} + ^{1}_{1}\text{H}.$$

We could also produce this radioactivity with the neutrons of boron + deuterons, but not with those of beryllium + deuterons or with slow neutrons. We were unable to detect this period in nitrogen bombarded by slow neutrons (beryllium + deuterons + paraffin).

RADIOACTIVE ISOTOPES OBTAINED BY 'NEUTRON LOSS'.

Source		Gamma rays			Neutrons			Radio-isotope produced	Half-period (min.)
		Li+H	Be+H	B+H	Li+D	Be+D	B+D		
	Energy in 10^6 eV.	17 5	⩽6·5	⩽14	⩽13·5	⩽4·5	⩽13		
Element irradiated	Isotopes								
8 O	16, 17, 18	2		—	—	—	—	^{15}O	2 1
29 Cu	63, 65	100	—	—	1200		300	^{62}Cu	10 5
31 Ga	69, 71	40		—	1200	—	500	^{68}Ga	60
35 Br	79, 81	20	—	—	500	—	600	^{78}Br	5
47 Ag	107, 109	25	—	—	700	—	300	^{106}Ag	24
49 In	113, 115	35	—	—	300	—	100	^{112}In	1
51 Sb	121, 123	10	—	—	2000	—	300	^{120}Sb	13

The figures give the relative initial activity (measured with a tube counter) observed in thick samples bombarded by gamma rays or neutrons. The values are expressed in arbitrary units and are reduced so as to correspond to samples of equal size, to equal ion current (at about 520 kV.), and to infinite time of exposure.

In gallium bombarded with neutrons from lithium + deuterons and boron + deuterons a new radioactivity decaying with a half-period of about 5 min. and having an intensity similar to that of the 60 min. period has been found. As this period seems to be identical with one of the periods produced in copper by neutron capture, it is probably due to ^{66}Cu, formed according to the reaction :

$$^{69}_{31}\text{Ga} + ^{1}_{0}n \rightarrow ^{66}_{29}\text{Cu} + ^{4}_{2}\text{He}.$$

We wish to thank Dr. W. B. Lewis and Mr. W. E. Burcham for putting their apparatus at our disposal, and Prof. E. N. da C. Andrade for lending us a sample of pure gallium.

Absorption of γ-Rays Measured by their Photo-effect in Beryllium

IT results from recent determinations of atomic masses, that in the photo-nuclear effect of radium C γ-rays in beryllium, only the hardest groups, namely, 2·2 × 10^6 eV., 2·0 × 10^6 eV. and 1·8 × 10^6 eV., can be efficient. The absorption of these γ-rays measured by the number of neutrons produced in beryllium should therefore be very nearly exponential without any preliminary filtering. However, Gentner[1] has found that the absorption curve obtained by this method exhibits a flat maximum for small thicknesses of absorbing material (lead or aluminium) and then decreases, at first with a coefficient corresponding to 0·9 × 10^6 eV., and afterwards more slowly. Gentner interprets these results by assuming that the observed maximum corresponds to the maximum intensity of the 0·9 × 10^6 eV. rays developed by the Compton effect from the primary rays, and that this quantum energy represents twice the energy necessary for extracting a neutron from the beryllium nucleus.

In view of these discrepancies, I have repeated these experiments using the following arrangement. About 120 gm. of beryllium contained in a thin-walled zinc box, 5 cm. × 5 cm. × 5 cm., was placed at 4 cm. distance from the source of γ-rays (50 mgm. of radium contained in platinum tubes kindly lent by the Maria Curie-Skłodowska Radium Institute, Warsaw). The activity excited in a silver foil placed against the box opposite the source was measured as a function of the thickness of different absorbers interposed between the box and the source. Paraffin wax was placed behind the box in order to increase the efficiency of the neutrons. The front side of the box exposed to the radium was covered by a sheet of cadmium in order to minimize the back-scattering of slow neutrons from the absorbing material. The results

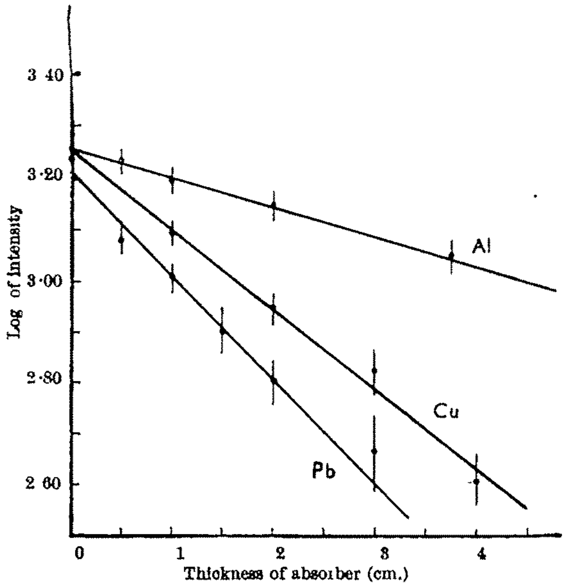

Fig. 1.

for absorption in lead, copper and aluminium are represented in Fig. 1.

The curves are exponential, the half-value thicknesses being 14 mm., 19 mm. and 52 mm. for lead, copper and aluminium respectively. I deduce for the atomic absorption coefficients: $\mu_{at}^{Pb} = 1{\cdot}51 \times 10^{-23}$, $\mu_{at}^{Cu} = 0{\cdot}434 \times 10^{-23}$, $\mu_{at.}^{Al} = 0{\cdot}215 \times 10^{-23}$. The best value found by comparison of theory and recent experimental work[1] for radium Cγ-rays filtered through 10-15 cm. lead is $\mu_{at.}^{Pb} = 1{\cdot}53 \times 10^{-23}$, and the values calculated for these rays for copper and aluminium using the figures given by Gentner[2] are $\mu_{at.}^{Cu} = 0{\cdot}439 \times 10^{-23}$ and $\mu_{at.}^{Al} = 0{\cdot}195 \times 10^{-23}$. The agreement is very satisfactory and shows that the efficient wave-length for neutron production is about equal to the mean wave-length—6·3 x.u., corresponding to $1{\cdot}96 \times 10^6$ eV. quantum energy—of rays filtered through 10-15 cm. lead.

The divergent results obtained by Gentner must probably be attributed to the back-scattering of slow neutrons from small thicknesses of the absorbing material. I performed some experiments in which the box was *not* protected by cadmium, and obtained a curve which without showing a maximum was nearly flat at the beginning. The effect of scattering is small in my arrangement because the sheet of beryllium is 5 cm. thick. With a smaller thickness of beryllium a maximum would certainly be observed.

I have compared also the efficiency of radium C and thorium C″ γ-rays in producing neutrons from beryllium and found, in agreement with Gentner, for equal intensities of γ-rays (filtered by 1 cm. of lead and measured by a Geiger counter) that the first source gives about twice the number of neutrons produced by the second source. This fact may be attributed to a nuclear resonance effect, or alternatively to the smaller efficiency of neutrons of higher kinetic energy, produced by the harder γ-rays of thorium C″[3]. Experiments now in course seem to support the later assumption.

Induced Radioactivity of Silver with Neutrons from Slow Deuterons

IN a recent paper[1] we have described experiments, in which artificial radioactivity of silver was produced by neutrons delivered by 25 kV.-deuterons. Some further results on this point are communicated in this note.

The first task was to decide whether a deuteron-deuteron process or the reaction deuteron-beryllium is the origin of our neutrons. For this purpose, the mica foil with the beryllium layer used in our first experiments was replaced by a similar foil without beryllium and the experiment repeated in the same way. The results from a series of a hundred runs do not show an effect comparable with that of the beryllium covered foil (though a very small effect, just about the order of magnitude of the statistical errors, possibly exists; but it would require far more runs to establish with certainty the reality of the effect). At all events, we can be sure that the neutrons which produced the activity measured in our first experiments are due to the process:

$${}^9_4\text{Be} + {}^2_1\text{H} \rightarrow {}^{10}_5\text{B} + {}^1_0n$$

In order to get information concerning the velocity of our neutrons, we tried to state the relation of the intensities of the two known periods of silver as a function of the velocity of the primary deuteron-ray. Since it is known that the shorter period is far more influenced by the slowing down of the neutrons, one can at least easily establish, by varying the energy of the primary radiation within the small range of our voltages (15–35 kV), whether the velocity of the neutrons is of the order of magnitude of that of the primary radiation, or not. If the energy of the effective neutrons is of the order of magnitude of 10^4 eV., we should expect a systematic variation of the intensity relation of the two periods; and conversely, a practically constant intensity relation would mean that the energy of the neutrons is large compared with the energy variation used, namely, about 10^4 eV.

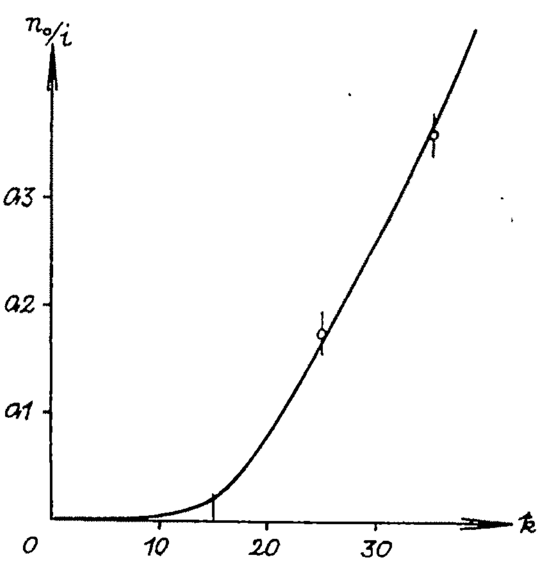

Fig. 1.

Unfortunately, the activity produced by the 15 kV.-beam was too small to permit us to carry out this programme entirely. With this voltage our ion-current was not sufficient to produce in 150 runs an activity exceeding the statistical uncertainties. From 150 measurements with 35 kV. we got very exact decay curves, giving the following results for the half-value periods and the intensity relation (which may be defined by two coefficients C_1 and C_2, where $C_1 + C_2 = 1$): $T_1 = 24 \pm 5$ sec., $T_2 = 110 \pm 12$ sec., $C_2 = 0{\cdot}58 \pm 0{\cdot}06$. Using these values for the half-periods, one gets the best agreement with the experimental decay curves from the 25 kV.-measurements with $C_2 = 0{\cdot}50 \pm 0{\cdot}07$. The second value is indeed smaller than the first, as might be expected for neutrons of about 10^4 eV., but the variation is just within the possible error, so that it is again impossible to decide with certainty the point in question.

Finally, it is of interest to examine the excitation curve for our low-voltage neutrons. In Fig. 1 we have plotted the total number n_0 of silver atoms transmutated in a single run (extrapolated from the decay curves) divided by the positive ray current in microamperes. We have found the yields: $< 0{\cdot}024$; $0{\cdot}176 \pm 0{\cdot}02$; $0{\cdot}360 \pm 0{\cdot}02$ respectively. Expressed in radium equivalents (that is, the values resulting from the comparison of our total induced activity with that of a preparation of radium-beryllium with known content of radium element) the yields are: $< 0\cdot2$; $6\cdot8$; 19 mgm.

Androgenic Activity of Ovarian Extracts

IT is well known that œstrogenic activity may be shown by extracts of testes and by extracts of urine from the males of certain species. Conversely, androgenic activity can readily be demonstrated in the urine of normal women, and Hill and Gardner[1] have shown that, under certain conditions, the atrophic seminal vesicles of castrated mice can be restored by ovarian grafts. Further, since the comb of the domestic hen atrophies after ovariectomy and responds to male hormone but not to œstrone, its increase in size during the laying season presumably indicates production of androgenic substance by the active ovary.

So far, however, androgenic activity does not seem to have been demonstrated in ovarian extracts, possibly because much larger amounts of male hormone than of œstrone or œstradiol, in terms of crystalline substance, are required to evoke a significant biological reaction. By the use of Fussganger's highly sensitive modification[2] of the capon test—direct unction of the comb with the extract—we have now been able to demonstrate androgenic activity in two crude alcohol-acetone-ether extracts of pig ovaries. The first extract was qualitatively tested on the combs of two bantam capons and produced growth (L + H) in five days of 11 mm. and 7 mm., a clear-cut response. The second, quantitatively tested on ten Leghorn capons by the application to each of a total of 0·125 c.c. of the oily extract over five days, produced an average growth of 4 mm., about the same as that given by the similar administration of 2·5 γ androsterone, or 1/40 I.U. The yield of extract was 3·9 gm. per kgm. of fresh tissue, so that the androgenic activity of pig ovaries would seem to be rather less than 1 I.U. per kgm. Suitable control tests with arachis oil solutions of œstrone, œstradiol and œstriol gave negative results, and it is likely therefore that the androgenic activity of the ovarian extracts was due to the presence of substances of the androsterone-testosterone group.

This result is of obvious significance in relation to the origin of the androgenic material in the normal human female. A number of observations suggest that the adrenals are one site of elaboration. Thus Reichstein[3] has isolated an androgenic diketone from the adrenal, while, examined by the unction technique, a crude extract of horse adrenal was slightly androgenic, and a highly concentrated discard fraction of pig adrenals, kindly supplied by Dr. Reichstein, gave good growth. Further, Simpson, de Fremery and Macbeth[4] have shown that very large amounts of androgenic substance may be present in the urine of women with virilism of adrenal origin, and Callow[5] has isolated as much as 110 mgm. per litre of *trans*-dehydroandrosterone from the urine of a female child with an adrenal tumour. Finally, in conjunction with Dr. Callow and Dr. Levy Simpson, it has recently been shown that considerable amounts of androgenic material may be found in the urine of ovariectomized women. Nevertheless, the presence of androgenic activity in ovarian extracts shows that the female gonad must also be considered as a possible source of at least a part of the androgenic material found in the normal human female.

Inactivation of Vaccinia Virus by Ascorbic Acid and Glutathione

JUNGEBLUT and his co-workers[1] have shown that the virus of poliomyelitis and diphtheria toxin were inactivated by ascorbic acid. One of us[2] has shown that addition of ascorbic acid to cultures of *C. diphtheriæ* leads to production of relatively atoxic filtrates. Further studies on the nature of this interaction established a reasonable presumption that there was an oxido-reduction between the ascorbic acid and toxophore group of diphtheria toxin.

It occurred to us that if this is the type of reaction involved, other viruses might also be inactivated in the same manner. Experiments conducted with vaccinia virus gave positive results. Relatively small amounts of ascorbic acid inactivated many infective doses of the virus. Similar results were obtained also with glutathione, but this substance proved much less active than ascorbic acid in the same concentration.

The procedure employed was briefly as follows: Vaccinia virus was inoculated into a rabbit testicle. After 3–4 days the testicle was removed, ground with sand, suspended in saline and various decimal dilutions made in saline. These suspensions were mixed with equal volumes of freshly prepared solutions of ascorbic acid. The mixtures were incubated for a half-hour at 37° C. and then kept at icebox temperature. Untreated control suspensions were kept under the same conditions. At various intervals, 0·2 c.c. of the different mixtures were injected intracutaneously into rabbits. A summary of four different experiments is tabulated below:

Vitamin Conc.	Incubation Time	Infective doses inactivated
1 · 20,000	3 hours	10*
1 : 2,000	3 ,,	100
1 : 200	3 ,,	1,000
1 . 20,000	6 ,,	10
1 : 2,000	6 ,,	100
1 : 20,000	24 ,,	10
1 : 2,000	24 ,,	1,000*
1 : 200	24 ,,	10,000

* = incomplete neutralization, that is, delayed reaction and milder lesion. Full number = infective doses completely inactivated

It will be noted that the ascorbic acid inactivates the virus and that the degree of inactivation depends on the concentration of the vitamin and the time interval during which it is allowed to act.

Similar tests were made with glutathione. This substance proved much less active than ascorbic acid. A dilution of 1 : 20,000 failed to inactivate virus in 24 hours, while a dilution of 1 : 200 inactivated 10 doses completely and 100 infective doses partially.

It appears, therefore, that ascorbic acid has the same effect on vaccine virus as on the virus of poliomyelitis and on diphtheria toxin. Preliminary experiments indicate a similar effect on coli phage. It may well be, therefore, that the phenomenon is a general one and is related to a common or related group in the chemical composition of viruses and diphtheria toxin, effected by oxido-reducing substances, of which ascorbic acid is the most active.

Further investigations are in progress.

Correlation Phenomena and Hormones in *Selaginella*

IT has been known for a long time that the angle-meristems present at every branching of *Selaginella* shoots, which normally give rise to rhizophores, may be induced to develop as leafy shoots instead of rhizophores[1]. This altered development occurs when pieces of shoot including a branching but with the shoot apices removed are used as cuttings. This is illustrated for *S. Martensii* in Fig. 1 *a*, which depicts a specimen from an experiment in which fourteen pieces of shoot were used. Thirteen of these showed the development of leafy shoots from the angle-meristems while the remaining one showed no further development.

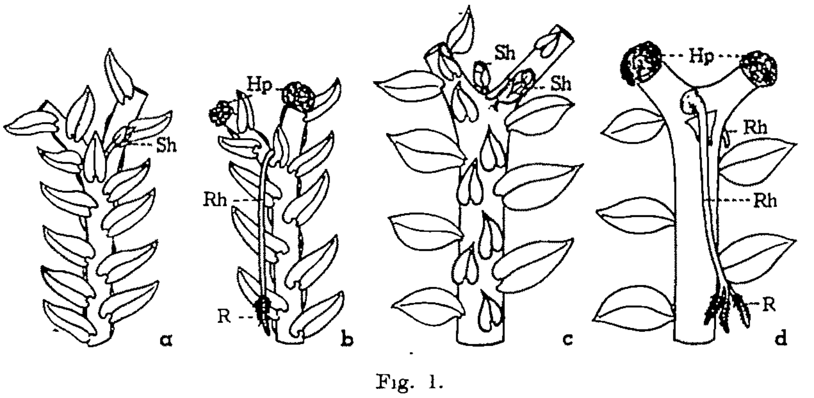

Fig. 1.

Selaginella Martensii. (*a*) UNTREATED LENGTH OF SHOOT; (*b*) LENGTH OF SHOOT WITH HETEROAUXIN PASTE; (*c*) AND (*d*) COMPARABLE LENGTHS OF SHOOT OF *S. Lobbii*. *Sh*, SHOOT; *Rh*, RHIZOPHORE; *R*, ROOT; *Hp*, HETEROAUXIN PASTE. (× 1¼).

The presence of a correlating influence diffusing backwards from the shoot apices has been inferred from the known facts, and it seemed worth while to investigate whether hormones such as heteroauxin (3-indole acetic acid) were concerned. Pieces of shoot were prepared as above, and the cut upper surfaces were then smeared with heteroauxin paste (prepared by the method described by Laibach[2]). Twelve pieces of shoot were used, and all showed the development of a rhizophore from the angle-meristem (see Fig. 1 *b*). Comparable results have been obtained with the more strongly growing *S. Lobbii*, which frequently shows two angle-meristems in an active condition at each branching. In an experiment with eleven pieces of shoot treated with heteroauxin paste, seven specimens showed the development of a single rhizophore, the other meristem remaining dormant; two showed the development of two rhizophores (see Fig. 1 *d*); one the development of a rhizophore followed by the development of a shoot from the other meristem; the remaining specimen showed no further development. Similar shoot pieces without heteroauxin paste showed the development of one or two leafy shoots (see Fig. 1 *c*); no rhizophores were formed.

These preliminary experiments indicate that the presence or absence of heteroauxin is an effective factor in determining whether an angle-meristem shall develop as a rhizophore, leafless and positively geotropic, or as a plagiotropic leafy shoot. They do not prove that the correlating influence normally exercised by the shoot apex is in the nature of a hormone mechanism, but they lend support to this view.

A more extensive series of experiments relating to correlation phenomena in *Selaginella* is in progress.

A Device for the Observation of Root Growth in the Soil

STUDIES of root systems have in the past been accomplished by various methods of excavation *in situ* or by the growing of plants in specially constructed boxes which can be dismantled to allow removal of the soil. It is impossible to conduct developmental studies by this means unless a number of subjects are examined at various stages of their growth, and in any event the process is extremely laborious. In work on fruit trees at East Malling, Rogers[1] has designed observation trenches which are in the form of a walled chamber fitted with plate-glass windows. This gives a view of rootlets impinging against the glass.

The necessity for this type of study upon arable crops and grasses has led me to devise a cheap and convenient means suited to field conditions. Land under rotation on a commercially run farm must undergo cultural operations in winter which make it imperative to move the units after the crop is harvested. Cheapness renders it possible to install a sufficient number of points of observation to satisfy statistical needs. A less permanent and expensive method is therefore desirable than in the case of an experimental orchard.

Glass tubes, closed at the lower end, are let into the soil down holes bored to a slightly larger diameter.

A certain amount of packing with dry soil from the various depths is necessary. The glass cylinder may be specially constructed for the purpose, but lamp glasses cemented end to end to a depth of three or four feet have proved very satisfactory. Half-section drain-pipes faced with glass and other types of shaft have also been utilized. Good quality horticultural glass has been found to take the strain in cases where a lamp glass is not employed. The top of the shaft is closed with a metal lid designed to collect rain-water. The glass may be marked into squares to facilitate observation and sketching

The method of viewing the roots is by a mirror mounted at the end of a metal rod with a screw adjustment to allow tilting to a convenient angle. A small electric bulb is fitted above the mirror and this is connected to a pocket torch fixed to the upper extremity of the rod. One instrument, of adjustable length, to which mirrors of convenient sizes can be attached, serves for every type of shaft.

In preliminary observations on *Lolium perenne*, the lamp glass method has provided a clear image at an inclusive cost of not more than half a crown per square foot of area observed. This is a very small fraction of the cost of the permanent chamber.

It is hoped, this year, to conduct a series of observations upon such problems as the effect of continual cutting upon the root systems of grasses and the influence of a concentrated layer of fertilizer upon root growth. The progression of the root system in sugar beet will also be observed.

Distribution of Ultra-High-Frequency Currents in Long Antennæ

IN connexion with some problems concerning the action of ultra-short wireless waves on frame aerials, it was found necessary to know how ultra-high-frequency currents were distributed on long straight aerials. It has usually been assumed that such currents were distributed sinusoidally, and Wilmotte[1] has shown both theoretically and experimentally that this is so in the particular case of a long vertical antenna with a concentrated E.M.F. at the foot of the aerial.

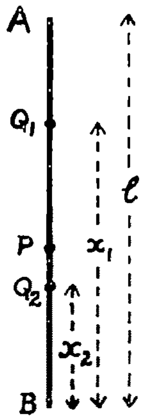

Fig. 1.

If a concentrated high frequency E.M.F. be applied at any point P (Fig. 1), then it can be shown that the currents in the portions of the wire above and below P are distributed sinusoidally with current nodes at half wave-length intervals measured from both A and B. That is, if I_1 be the current at Q_1 and I_2 that at Q_2 then

$$I_1 \propto \sin\frac{2\pi(l - x_1)}{\lambda} \quad \text{and} \quad I_2 \propto \sin\frac{2\pi x_2}{\lambda},$$

where l is the length of the antenna and λ is the length of the wave. Furthermore, the currents in the two parts are dependent one upon the other in such a way that, when AP (say) is an integral number of half wave-lengths, the current in BP is a minimum (theoretically zero) whatever be the length of BP*, and when AP is an odd number of quarter wave-lengths, the current in BP is a maximum. In a similar way, the current in AP is dependent on the ratio of BP to λ.

This current distribution only occurs when the input energy is concentrated at a given point of the antenna, and is therefore applicable to long transmitting aerials if they are coupled by a coil of small dimensions to an ultra-high-frequency oscillator.

With a long isolated receiving antenna in a uniform ultra-high-frequency electromagnetic field, the current distribution seems to be much more complex. Its amplitude variation with distance x along the aerial wire is given by the theoretical expression:

$$I_0 = K \sec\frac{\pi l}{\lambda} \sin\frac{\pi x}{\lambda} \sin\frac{\pi}{\lambda}(l - x),$$

where K is a constant. This reduces to $K \sin^2 \pi x/\lambda$ when $l = n\lambda$. The general expression shows that current nodes occur at intervals of one whole wave-length measured from both ends of the antenna. The nodes measured from one end of the antenna therefore overlap those measured from the other end in such a way that the two central nodes gradually come closer together as the aerial increases in length from one to two wave-lengths, and then gradually separate as the length of the aerial increases from two to three wave-lengths, and so on. The symmetrical disposition of these central current nodes and antinodes and their dependence upon the ratio l/λ will presumably determine the best positions for tapping points for the passage of energy to and from the antenna.

Preliminary experiments have supported the above conclusions, but the practical current distribution graphs for long transmitting and receiving aerials and the measured critical lengths are naturally slightly modified by the fact that the resistance and leakage of the aerial cannot be neglected when compared respectively with the inductive and capacitive reactance components of its impedance.

It is proposed to publish a full account of this work in the immediate future.

Fall in Air Temperature during the Solar Eclipse of December 13-14, 1936

AT a recent meeting of the Royal Astronomical Society[1], a discussion took place on observations of temperature changes made by Dr. John L. Haughton on board the *Strathaird*, during the total solar eclipse of June 19, 1936.

From this discussion, it appears that the amount of fall in air temperature which can actually take place during solar eclipses is very variable. It must depend to a large extent on the time of the eclipse, the meteorological conditions, and the geographical aspect of the point of observation.

During the annular eclipse of December 13–14, 1936, some fairly large falls of air temperature were recorded in New Zealand. Probably the most reliable and complete record is that obtained at the Meteorological Observatory, Wellington. By permission of Dr. E. Kidson, director of Meteorological Services, a tracing of this record is given here (Fig. 1). The record is from the Short and Mason M.O. pattern thermograph, in a Stevenson screen, under standard conditions for recording air temperature, located at an altitude of 415 ft. above sea-level. The thermograph was checked at intervals by comparison with a standard thermometer in the same screen. These check readings are indicated by black dots on the graph. A check reading at 10 hours 30 minutes, New Zealand Mean Time, just before the minimum, shows that the correction to the thermograph at minimum must have been very small. Another check reading at 11 hours, during the rise, indicates a slight lag in the rise of the thermograph. Evidently the minimum temperature occurred within a few minutes after the time of maximum eclipse, of which the magnitude at Wellington was 0·85. During the eclipse the sky was cloudless, and the normal course of the temperature curve would probably have been close to the dotted line shown in the graph. The difference between this line and the lowest point of the temperature curve corresponds to a temperature difference of 4·9° C.; which must be attributed to the eclipse. Records of eclipse temperature changes have been summarized by Clayton[2]; and from the figures given, it appears that the fall in air temperature at Wellington during the eclipse of December 13–14, 1936, was abnormally large, particularly for a partial eclipse.

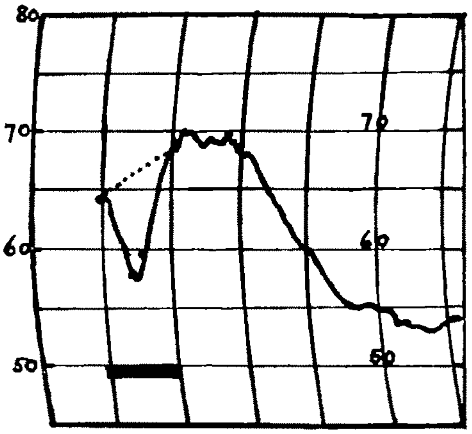

Fig. 1.

THERMOGRAPH RECORD OF AIR TEMPERATURE, KELBURN OBSERVATORY, WELLINGTON, N.Z., DECEMBER 14, 1936. THE PERIOD COVERED BY THE ECLIPSE IS INDICATED BY A BLACK STRIP BELOW THE THERMOGRAPH TRACE. BLACK DOTS INDICATE STANDARD THERMOMETER READINGS.

At Pukekohe, near the central line of the eclipse, observations of a thermometer in a Stevenson screen were made by the eclipse party under the leadership of Mr. C. B. Michie. A fall of 2·5° C. was observed during the eclipse, but this value may have to be increased slightly when the normal temperature change is taken into account[3]. The small fall at Pukekohe as compared with Wellington is due mainly to the effect of clouds at the former place. At New Plymouth, a short distance south of the central eclipse zone, a fall of 4·2° C. was registered by a thermometer in the shade[3].

Apart from the indications of the thermometer, the fall in air temperature was most apparent. The day of the eclipse was a public holiday, and at Wellington the weather was fine and warm. Consequently, a larger number of people than usual were out of doors; and to many, the chilliness of the atmosphere was the most outstanding phenomenon accompanying the eclipse.

Meteorites and the Craters on the Moon

DR. SPENCER's article on this subject in NATURE of April 17 will have been read with interest by many astronomers who have held some of the views set forth therein for more than twenty years. I am unable to say who it was that first realized that meteoric impacts on the surface of the moon would be of an explosive nature, and would therefore give rise to circular craters; but, so far as I know, this most important consideration was first brought to the public attention of astronomers by the late Prof. A. W. Bickerton, in the course of discussions at meetings of the British Astronomical Association in 1915[1].

Mr. A. C. Gifford, whose admirable treatment of the subject in more than one publication is referred to by Dr. Spencer, has shown, to my mind conclusively, that the meteoric theory is physically and dynamically sound, and that it affords the only satisfactory explanation of the lunar craters.

Mr. Gifford's work is well known to astronomers, and the whole question has several times been the subject of debate in recent years at meetings of the British Astronomical Association; so it can scarcely be said that the subject has not been duly ventilated. It is, however, a fact that the writers of some recent text-books have shown rather a conservative attitude, almost as though it were desirable to save the time-honoured volcanic theory at all costs, in spite of its many difficulties.

The apparent absence of large explosion craters from the surface of the earth was one of the most serious objections to the meteoric theory; but, now that Dr. Spencer has assured us that this is by no means a fatal difficulty, is it too much to hope that in future this attractive hypothesis will receive the serious attention which it most certainly merits?

Determination of the Atomic Parameters in Anthraquinone Crystals

THE space group of anthraquinone crystals was found previously[1] to be D_{2h}^{13} *Pmmn*. The estimates of intensities of reflections from a large number of planes published have been utilized for the determination of atomic parameters. The best agreement has been found with the following orientations of the anthraquinone molecules. One molecule is placed with its centre having the parameters $x/a = 0 \cdot 25$, $y/b = 0 \cdot 142$ and $z/c = 0 \cdot 056$. Starting with the molecule placed with its plane parallel to the *ab* face, the correct position is obtained by rotating it by 1° about the z-axis, by 9° about the y-axis and by 30° about the x-axis. The two oxygen atoms are inclined to the carbon skeleton on the two sides but unsymmetrically. The positions and orientations of the other seven molecules in the unit cell are obtained from the equivalent positions corresponding to the space group D_{2h}^{13} *Pmmn*. The carbon skeleton has a plane structure with true hexagons and C—C distance the same as that in anthracene[2]. This is in very striking contrast to benzoquinone, in which the benzene ring is found to be deformed[3]. The complete details of the parameters and the comparison between the calculated and estimated intensities will be published elsewhere.

In conclusion, I wish to express my sincere thanks to Dr. K. Banerjee for his kind interest in the work.

Points from Foregoing Letters

DETAILS concerning a natural bridge, formed by drifting materials, across the Nile below the Folar rapids (to which imperfect reference was made by Emil Ludwig in "Life Story of a River") are given by E. J. Wayland. Dr. H. E. Hurst supplies further information concerning the way in which such bridges come into existence, and suggests that pilots of the Imperial Airways who pass near this particular one during their flights might be asked to collaborate by keeping notes of its change with time.

A table of radioactive isotopes of oxygen, copper, gallium, bromine, silver, indium and antimony, the production of which can only be ascribed to the loss, and not to the capture, of neutrons, is given by W. Y. Chang, M. Goldhaber and R. Sagane. The loss of neutrons was brought about by irradiating with gamma rays of high energy produced by bombardment of lithium, beryllium or boron with protons, or by means of neutrons obtained from the same elements bombarded with deuterons.

J. Rotblat has obtained absorption curves of radium C γ-rays in lead, copper and aluminium, measuring the intensity of the γ-rays by the activity of a silver foil exposed to neutrons from a sample of beryllium irradiated by the rays. The curves are exponential and correspond to the mean quantum energy of $1 \cdot 96 \times 10^6$ eV., showing, in agreement with recent mass data, that only the hardest groups of these γ-rays are capable of extracting neutrons from beryllium nuclei. The divergent results obtained by Gentner are attributed to the back-scattering of slow neutrons.

When beryllium-containing mica is bombarded with slow (25 kV.) deuterons, neutrons are formed which induce radioactivity in silver. These neutrons, according to further experiments by E. Bertl, Prof. R. Furth, F. Oborl and Dr. K. Sitte, arise from the beryllium-deuterium nuclear reaction. The authors describe other experiments intended to determine the energy of the active neutrons, but these have proved, as yet, indecisive. They also give a curve showing the neutrons produced by deuterons of varying energy (0–35 kV.)

The combs of bantam and Leghorn capons can be made to grow, according to Dr. A. S. Parkes, by direct application of an alcohol-acetone-ether extract of pig ovaries, which indicates an androgenic activity of ovarian extracts due apparently to the presence of substances of the androsterone-testosterone group. The author refers to previous experiments which show that the adrenal glands also produce male sex hormones.

Results showing that small amounts of ascorbic acid (vitamin C) can inactivate infective doses of vaccinia virus inoculated into a rabbit testicle are given by I. J. Kligler and H. Bernkopf. Glutathione has a similar effect, but to a lesser degree, and the authors suggest that the action depends upon the oxido-reducing properties of ascorbic acid and glutathione.

Dr. S. Williams describes preliminary experiments on *Selaginella Martensii* and *S. Lobbii* which show that the presence or absence of heteroauxin is an effective factor in determining whether an angle-meristem shall develop as a rhizophore or as a leafy shoot.

A simple method of observing root growth under normal conditions is described by Dr. G. H. Bates. Glass tubes closed at the lower end are let into the soil in holes bored to a slightly larger diameter, and the roots are viewed at intervals by means of an arrangement of a mirror and an electric bulb.

A thermograph showing the falling of air temperature during the solar eclipse on December 14, 1936, at Wellington, New Zealand, is submitted by R. C. Hayes.

The current distribution in a long transmitting aerial, according to Prof. L. S. Palmer and Mr. K. G. Gillard, varies sinusoidally, with current nodes every half wave-length along the two parts of the aerial which are above and below the point of energy input, and the length of one part may be such that the current in the other part is either zero or a maximum. With a long receiving aerial, current nodes occur every *whole* wave-length measured from both ends of the aerial.

Prof. B. C. Guha has determined the atomic parameters of anthraquinone crystals. He finds that the carbon skeleton has a plane structure with C—C distances the same as in anthracene; and that the C—O bonds are inclined unsymmetrically to the carbon plane.

Research Items

Food of the Maya Indians

THREE expeditions to Yucatan have established the fact that male Maya in the Chichen Itza area have a basal heat production averaging from five to eight per cent higher than the commonly accepted standards for white men living in the northern parts of the United States. At the same time, whereas natives of sub-tropical areas usually have a metabolism lower than northern standards, the metabolism of the Maya is relatively high and is combined with a low heart rate and low blood pressure. In view of the possibility of a relation of this condition to diet, a quantitative and qualitative study of the Mayan present-day diet has been undertaken by Dr. Francis G. Benedict, director of the Nutrition Laboratory, and Dr. Morris Steggerda (Carnegie Institution, Washington, D.C. : *Contrib. Amer. Arch.*, 3, 18). It was also anticipated that this investigation might throw light on the diet and food customs of the prehistoric Maya. In the remoter parts of Yucatan, the diet of the modern Maya is still almost entirely independent of white man's civilization. The basic food is maize, with its products, but beans, squash, chile and native meat are also eaten, with, on the sea coast, some sea-food. Seasonings, such as garlic, pepper, leaves, cloves and chile, play an important part. This diet is essentially the same as is recorded in literary sources for the period 1500–1700, and probably goes back to a much earlier date. Precise analysis of protein, fat, and energy content of many items in the daily diet and of daily meals were made. On the average, 73 per cent of the daily energy intake comes from maize. The daily protein intake per individual averaged 74 gm., low rather than high. The daily energy intake averaged 2,565 total calories, low as compared with the American labourer (*c.* 3,500 calories). The energy intake averaged only 66 per cent above the basal needs shown by measured basal heat production. The basal metabolism is not explained, and may be an environmental or racial factor.

The Electric Eel

THE electric discharge of certain fishes has often aroused scientific interest and popular curiosity, and of all electric fishes, the electric eel (*Electrophorus electricus*) is the largest, and develops most power. In their account of the electric discharge of this species (*Zoologica*, 22, 1 ; 1937), C. W. Coates and R. T. Cox summarize the earlier information and pay tribute to the accuracy of Faraday's observations of 1839 and 1844. They themselves have measured the voltages and speeds of propagation of the electric impulse along the body of electric eels, finding that an anterior point on the body is always positive to a posterior point. Peak voltages of the order of 300 and peak wattage of the order of 40 are about the maximum for eels exceeding 50 cm. in length. The velocity of the pulse along the body is between 500 and 1,000 metres a second, and the discharges commonly occur in trains of one minor member followed by three to six major members separated by intervals of about 0·005 sec. The release of the electric discharge is likened to the release of ordinary muscular energy, and the discharge itself must be a cumulative effect of the activity of a large number of cellular elements, which may possibly be fully charged in the inactive state and are connected in series during the discharge.

Citrus Culture in Egypt

BULLETIN No. 44 (1936) of the Egyptian Ministry of Agriculture (Hort. Section) first published in 1924 and written by T. W. Brown, has been revised and brought up to date by Abbas el Sawy. It is a comprehensive treatise on methods of propagation and cultivation of citrus fruits, and should serve as a reliable manual for growers in Egypt with little previous experience of fruit growing. Citrus culture in Egypt has made rapid strides during recent years, the acreage under oranges and mandarines having risen from 6,215 acres in 1923 to 18,229 acres in 1934. In 1925, 7,375,297 kgm. of citrus fruits were imported, while in 1934 this was reduced to 897,808 kgm., and 2,867,469 kgm. of oranges and mandarines were exported. The information provided by the bulletin will undoubtedly prove an invaluable guide in this expanding industry. It is clearly written and contains information on all the cultural operations, including sections on budding and grafting and a critical account of the various rootstocks available. Every phase of the industry is dealt with from the preparation of the ground to the packing of the fruit, particular attention being given to irrigation and manuring. The latter half of the bulletin consists of an excellent catalogue of the numerous varieties of citrus fruits. This is very well illustrated, and the varietal characteristics are given in detail together with notes on the origin and history of the varieties.

Evaporation Records in the Netherlands

IN *Mededeelingen en Verhandelingen*, 39, 1936, Dr. C. Braak discusses evaporation records in the Netherlands and compares the results obtained with those for certain places in Germany and Switzerland. There are some very long records available in Holland, for example, at the Helder, but unfortunately insufficient continuity of method and lack of precise information about the earlier part of this record greatly reduces its value. For the period 1909–35, comparative figures are available for the evaporation from similar pans containing water at de Bilt and the Helder. The averages for the months of least and greatest evaporation are (1) de Bilt, 15 mm. in December and 133 mm. in July ; (2) the Helder, 25 mm. in January and 158 mm. in July. A table is included giving individual monthly totals for de Bilt from May 1897 to December 1935, with a few gaps in 1902 and 1903. Figures for a number of stations with shorter records are compared ; but it is concluded that the differences are caused more by variations of instrumental exposure than by climatic contrasts. Observations made with a floating pan in a pond near the Meteorological Institute, de Bilt, since 1932, are compared with similar observations made by Bindemann in a small lake north-east of Berlin (the Grimnitzee), and others made on the Yssel lake (the former Zuyder Zee) are compared with figures relating to two Swiss lakes. The paper closes with a discussion of the values of the constant in a well-known evaporation formula which makes the evaporation proportional to the saturation deficit, allowance being made for the influence of temperature on the mobility of the water vapour molecules and for the influence of wind speed.

Origin of Cosmic Rays

IN the issue of the *Journal of the Franklin Institute* of April, Dr. M. C. Holmes of the West Virginia University puts forward a theory of a terrestrial origin for cosmic rays. This is based on the Debye water molecule having its positive end heavier than its negative, and in consequence in a gravitational field having its positive end downwards when free to move. Except in polar regions, where it may be frozen, it has its negative end upwards and provides the negative charge known to exist on the earth's surface. Any positive charge produced in the stratosphere by solar radiation will move down towards the earth's negative charge until it reaches the polar air currents of the troposphere, which will carry it towards one of the poles, where positive charges will accumulate. An electric field will be produced between these charges and the negative charge on the non-polar regions, which will supply the 10^9 volts required to account for the production of cosmic rays. Dr. Holmes considers further the application of the same principle to account for the banded appearance of Jupiter, the rings of Saturn and other planetary phenomena.

Reactions of Atomic Deuterium with Paraffin Hydrocarbons

IN addition to an investigation of the photosensitized reaction between methane and deuterium, an investigation of the interaction of atomic deuterium with methane, ethane, propane and butane for temperatures up to 310° C. has been carried out at Princeton University (Taylor *et al.*, *J. Chem. Phys.*, 5, 205; 1937). The nature of the reaction products and the extent of deuteration have been determined by two methods, a fractionation method and a thermal method. For methane, no exchange occurred below 200° C. and at 310° C. the exchange amounted to ten per cent. At temperatures above 27° C. ethane is decomposed by atomic deuterium yielding methane of high deuterium content, but the rate does not become measurable until 100° C., and thereafter increases as the temperature rises. Both propane and butane are relatively slightly decomposed, the products containing a surprisingly large amount of highly deuterated methane. For methane it is impossible to decide between the mechanisms (*a*) $CH_4+D=CH_3D+H$, and (*b*) $CH_4+D=CH_3+HD$ with subsequent reaction of the methyl radical. The C-C bond is readily split by atomic deuterium at room temperatures, presumably by either (*a*) $D+C_2H_6=C_2H_5+HD$ or (*b*) $D+C_2H_6=CH_3+CH_3D$; and of these, (*b*) finds greater favour because of the high deuterium content of the resultant methanes. Above 100° C., deuteration of ethane becomes more pronounced and takes place at the expense of deuteromethanes. The experimental data further show that the deuteration of an alkyl radical occurs much more readily than deuteration of the hydrocarbon. Activation energies have been calculated and from these the bond energies for $CH_3—H$ and $CH_3—CH_3$ have been deduced.

New Mercury Vapour Discharge Lamps

ALL types of metal vapour discharge lamps require a series 'ballast' to prevent the current through the lamp rising to too high a value. In the Engineering Supplement to the *Siemens Magazine* of May, a description is given by J. N. Aldington and G. O. Stephens of the new low-wattage mercury vapour discharge lamps taking 80 watts and 125 watts respectively, which are now on the market. The ballast may be in the form of a choke coil or simply a filament which supplies useful light while limiting the current. The inner bulb of the new lamps is made of quartz. This substance can be operated at temperatures up to 1,000° C. without showing harmful discolorations. The quartz interior is mounted inside a lamp bulb of standard shape with a pearl finish. As is common with all types of high-pressure metal vapour discharge lamps, the new lamps require a few minutes after being switched into circuit before the full light output is attained. Under normal working conditions, the full light output is reached in approximately five minutes. When they are switched out of circuit, they require a period of three minutes before the arc will restrike. After this restriking period, full light output is attained in a shorter time. The radiation from the inner bulb is very rich in ultra-violet rays. For this reason, it is important that the lamps should not be operated if the outer bulb becomes accidentally broken. The inner surface of the outer bulb is coated with 'luminescent' powder; very efficient powders of this nature (both fluorescent and phosphorescent) are now prepared on a commercial scale. These powders are used to supply the red and blue light in which the mercury discharge is deficient.

Motion and Figure of the Moon

DR. H. SPENCER JONES has published a paper "The Mean Motion of the Lunar Perigee and Node and the Figure of the Moon" (*Mon. Not. Roy. Astro. Soc.*, 97, 5, March 1937) in which important conclusions are drawn regarding certain discrepancies in the observed libration results and those obtained by theoretical considerations. Prof. E. W. Brown's computations on the motions of the lunar perigee and node had neglected terms of the fourth and sixth order; these have now been taken into consideration. The motions of the perigee and node contain terms due to solar and planetary actions, the mass of the earth, the figures of the earth and moon, and a relativity correction. Accounting theoretically for all these except the figure of the moon, and comparing with observation, the residuals can be accounted for by the lunar figure. The well-known parameter f has been assigned various values by different investigators, and this has given rise to considerable speculation on certain discrepancies. If A, B, C, be the principal moments of inertia of the moon about its centre, f is defined as the ratio of $(B-A)/(C-A)$, and this can be determined, knowing the mean inclination of the moon's equator to the ecliptic, and also the amplitude of the moon's true libration in longitude. The former is known with considerable accuracy; the latter with less certainty. Dr. Spencer Jones now finds that $f=0·68\pm0·09$, in good agreement with the values deduced from the librations in longitude. The value of the ellipticity of the earth is found to be $1/e=296·08\pm0·95$, which is a little smaller than that obtained by Jeffreys, 296·38, who used the unrevised motions of the lunar perigee and node in his computations.

The Cyclol Theory and the 'Globular' Proteins*

By Dr. D. M. Wrinch

A NUMBER of facts relating to proteins[1] suggest that the polypeptides in native proteins are in a folded state[2,3]. The type of folding must be such as to imply the possibility of the regular and orderly arrangement of hundreds of amino acid residues, which to some extent at least is independent of the particular residues in question.

At present two types of folding have been suggested, the cyclol type[3,4] and the hydrogen bond type[5]. The search for other types of folding is being continued. So far, it has not proved possible to discard either theory on the grounds that the type of link postulated is out of the question. It is, therefore, very desirable to test these theories by checking their implications against known facts Accordingly it is now considered whether the cyclol theory can stand the test of the body of facts relating to the 'globular' proteins, established by Svedberg and his collaborators[6].

THE CYCLOL FABRIC

In previous communications the cyclol postulate has been applied directly to polypeptides, and a number of molecules, cyclol 6, cyclol 18 ... and the general cyclol fabric (Fig. 1) have been suggested for consideration. These are all of one polyhexagonal type, in which the individual hexagons are alternately '2-way' diazine hexagons sharing opposite sides with triazine hexagons and '3-way' triazine hexagons sharing alternate sides with diazine hexagons. In default of information as to the sides and angles of these hexagons, a mean value is at present adopted for the C—C and C—N distances indifferently, and the tetrahedral angle δ as the valency angle for C. The valency angle for N is also taken as δ, since it has this value in hexamethylene tetramine[7], in which, as in the cyclol fabric, each N atom is joined to three C atoms.

In accordance with these assumptions, the individual hexagons in the cyclol fabric are at present taken to be 'crumpled' as in cyclohexane. The mid-points of the sides of a 'crumpled' hexagon are the vertices of a plane hexagon, and the geometrical problems can be simplified by taking these plane hexagons as the fundamental units in a 'median' network which represents the cyclol in a new way, each 'crumpled' hexagon being replaced by a 'median' hexagon.

In previous communications the cyclols have been considered only in the case when all the median hexagons lie in one common plane. With this limitation there has, of course, been no question of building a closed (that is, a space-enclosing) cyclol. To do so, it is necessary to investigate the conditions under which a cyclol fabric can bend about a line. Evidently it is permissible for two abutting median hexagons to lie on different planes, if the angle between the planes is the tetrahedral angle δ. Thus a cyclol fabric need not have a single median plane, but may turn about certain lines provided that the angle between abutting median planes is δ. The problem of the possible existence of space-enclosing cyclols can then be stated precisely as follows. Is it possible for a cyclol network to bend across one line after another so that it joins up and thus surrounds a portion of space ? In other words, can a cyclol network be drawn, not on a plane but on the surface of some polyhedron such that the faces at any edge crossed by the network abut at the tetrahedral angle ?

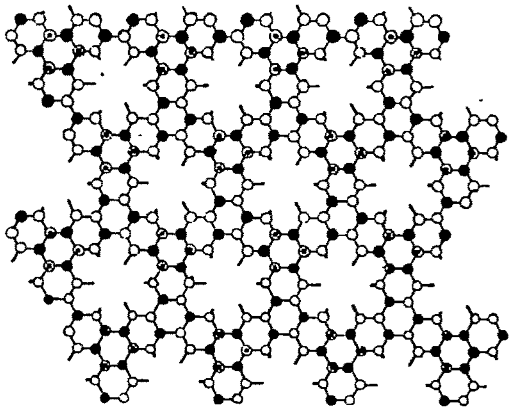

Fig. 1.

THE CYCLOL PATTERN. THE MEDIAN PLANE OF THE LAMINA IS THE PLANE OF THE PAPER. THE LAMINA HAS ITS 'FRONT' SURFACE ABOVE AND ITS 'BACK' SURFACE BELOW THE PAPER.

● = N.

○ = C(OH), PEPTIDE HYDROXYL UPWARDS.

○ = C(OH), PEPTIDE HYDROXYL DOWNWARDS.

○— = CHR, DIRECTION OF SIDE CHAIN INITIALLY OUTWARDS.

○- = CHR, DIRECTION OF SIDE CHAIN INITIALLY UPWARDS.

THE CLOSED CYCLOLS

To solve this problem, all the polyhedra in which some at least of the dihedral angles are equal to the tetrahedral angle will be considered in turn. As a first step it is remarked that among the regular and semi-regular polyhedra[8], only four satisfy the conditions. These are the truncated tetrahedron, the octahedron, the truncated octahedron and the skew triangular prism. On this occasion, as an example of this method of building megamolecules, attention is directed to the truncated tetrahedron, on which it has proved possible to draw closed cyclol networks. These networks form a linear series $C_1, C_2, \ldots C_n, \ldots$ which comprise $72, 288, \ldots 72n^2, \ldots$ amino acid residues. Figs. 2 and 3 show models of C_1 and C_2 in which the cyclol fabric is represented by the median hexagons. These models have 4 hexagonal faces, 4 triangular faces and 6 slits. The actual distribution of the (C—C—N) groups of atoms in the amino acid residues in the molecule can be inferred from the median hexagons, which are to be regarded simply as a shorthand notation.

The possibility of building closed cyclols on the other polyhedra mentioned above and on polyhedra which are not regular or semi-regular is being investigated. If they can be constructed they will also exist in linear series, each comprising numbers of residues represented by a quadratic function of the natural numbers 1, 2, . . . n, . . .

---

* This article is based upon lectures given at the Harvard, Yale and George Washington University Medical Schools and at the Medical Centre, Columbia University, in October and November 1936 Communicated to the Editor of NATURE on March 10, 1937

The cyclol hypothesis therefore predicts the existence of one or more series of 'space-enclosing' protein molecules, each series comprising numbers of residues given by a quadratic function of the natural numbers 1, 2, 3, . . . n, . . . and in particular of a series C_1, C_2, . . . C_n, . . . having the shape of truncated tetrahedra and comprising 72, 288, . . . $72n^2$, . . . residues.

These predictions are, it is claimed, confirmed by the results obtained by Svedberg and his collaborators[6].

(1) It is found that certain proteins are 'globular' molecules which, in appropriate circumstances, are monodisperse. The cyclol theory implies the existence of space-enclosing molecules containing certain specific numbers of amino acid residues: their polyhedral character is in accord with and offers an interpretation of the nature of this 'globularity'.

(2) It is found that certain molecules exist in different degrees of association in solutions of different pH, having a maximum molecular weight in a certain pH range and dissociating reversibly into molecules with submultiple molecular weights on one or both sides of this range. This is interpreted to mean that, in certain types of protein, the molecule will form multiple molecules at appropriate pH values by linkages between peptide hydroxyls or by salt linkages between side chains, the process of dissociation on changing the pH being reversible.

(3) It is found that the molecular weights of proteins are not distributed at random, but fall into a sequence of widely separated classes, the molecular weights in one class varying by as much as 15 per cent from a mean value. This is interpreted to mean that the proteins falling into one of these classes have a common structure as regards the arrangement of the constituent amino acids, and it is further suggested that each class connotes one closed cyclol network or an association of a certain number of such units. The variation in molecular weight within a class is then accounted for by the different selections of residues in the various proteins which can yield an average residue weight varying (say) from 100 to 135, which may also entail the presence of different numbers of water molecules in the molecule[9]. A further modification is also introduced if imino acid residues are present.

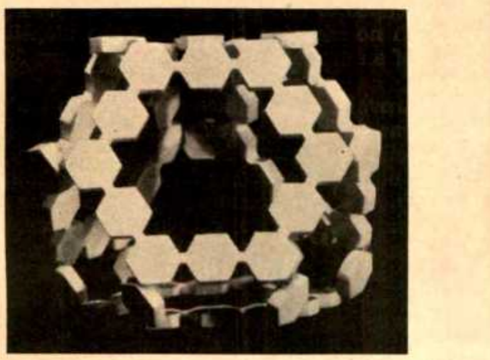

Fig. 2.

These tests are only qualitative. It would be of greater interest to apply more stringent quantitative tests. This will only be possible when data are available which give, for some of the 'globular' proteins, the shape of the molecule, the average value of the weights of the contained amino acid residues, the number of imino acid residues and the numbers of water molecules which form an integral part of the molecular structure.

It is, however, suggested for consideration in the future, that the group of proteins with molecular weights ranging from 33,600 to 40,500[10] are closed cyclol molecules of type C_2. This molecular weight class is of particular importance, since Svedberg has suggested that very many, possibly most, other proteins have molecular weights which are multiples of (say) 36,000.

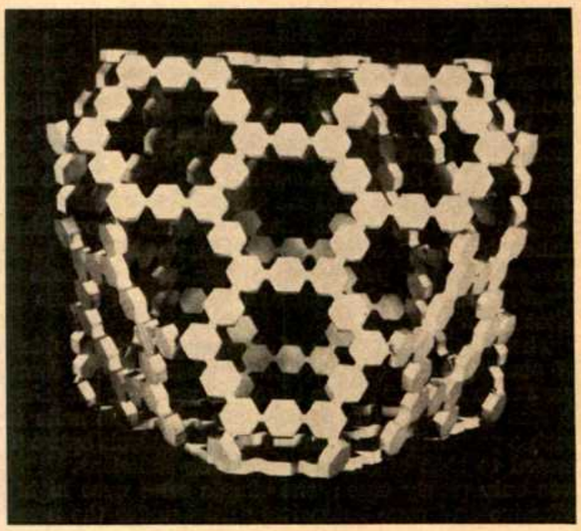

Fig. 3.

Full details of this work will appear shortly.

Postscript added May 28, 1937: My attention has been directed to recent work by Bergmann and his collaborators, which strongly confirms the conclusion reached above. In particular, it may here be put on record that one of the predictions has now been verified: Bergmann and Niemann (*J. Biol. Chem.*, **118**, 301; 1937) deduce from the chemical analysis of egg albumin that this molecule (which belongs to the group of proteins with molecular weights in the neighbourhood of 36,000) consists of exactly 288 residues as predicted by the cyclol hypothesis. Full details of my work are in course of publication in the *Proceedings of the Royal Society*.

Chemistry and Agriculture

THE thirty-eighth Bedson Lecture was delivered by Sir John Russell, director of the Rothamsted Experimental Station, on "Applications of Chemistry to Modern Food Production", at Armstrong College, Newcastle-on-Tyne, on May 21.

Sir John approached the problem by a short survey of British agriculture. His conclusions are: we are eating less bread but more meat, vegetables, butter, cheese to-day than in 1913, and although home production of milk, potatoes and vegetables is high, the home production of butter and flour is low, a matter of significance from the point of view of defence. The farmer, he said, must be judged on his own efficiency and not on the ultimate bulk production of agriculture, and statistics show that although there are fewer farmers now than in 1913, the output per person is greater and he feeds a greater number of persons than do the farmers of most other countries.

The classical approach of chemistry to the problem of plant growth was to find a substitute for farmyard manure, and at the time this was first broached it was suggested that a mixture of simple salts in such a proportion that the ultimate analysis approximated to that of manure would be sufficient. This was only partly true; the simple salts were highly effective and were extensively used under the name of artificial fertilizers, but the optimum proportions could be ascertained only by field trial. Interesting consequences followed from the circumstance that these fertilizers contained not only the specified plant nutrient but various amounts of other elements also. Extensive use of chemical fertilizers pushed up production for foodstuffs even where the actual acreage under cultivation has fallen.

Less is known of the more complex problem of the actual elements necessary to plant growth and their action. Science is advancing along two lines of investigation: trial and error methods and systematic statistical investigation. With regard to the function of the necessary elements, a study of plant deficiency diseases has proved useful. Examples of the results are: the addition of borax in certain conditions causes better growth of certain plants; and traces of manganese, copper and other elements appear to be essential to good growth. Some plants will take up particular nutrients more readily than others, so that the correct choice of a fertilizer will lead to preferential growth of these plants.

The soil is now receiving attention from chemists. One method of attack is to carry out field experiments in different types of soil with the same groups of fertilizers and to correlate the results with those of chemical examination. The method is slow and has to be rigorously controlled on a statistical basis.

Finally, Sir John dealt with the organic constituents of manure and described how experiments are carried out from two directions: the investigation of extracts of manure and the use of known organic compounds in growth tests. Examples of compounds exercising a marked effect on growth are indoleacetic acid and naphthalene-acetic acid.

Macculloch's Geological Map of Scotland

WHEN Henry T. de la Beche was trying, in the early eighteen-thirties, to persuade the Government to allow him to undertake an official geological survey of Great Britain, he encountered many objections of a financial nature. Even in 1840, five years after the "Ordnance Geological Survey", as it was at first called, had been officially established, and de la Beche sought permission to spend the winter in London instead of in the field, a letter from the Board of Ordnance stated that the authorities had "adverted to what occurred in respect of the Scotch Geological Survey, and they desire that special care may be taken to prevent the occurrence of a similar fault in the English Survey".

As a result of the perusal of a Parliamentary paper dealing with the expenses of the "Mineralogical Survey of Scotland", submitted to the Commons in 1830, and of the minute books of the Highland and Agricultural Society of Scotland, Mr. V. A. Eyles has been able to show exactly what transpired in Scotland to make the authorities reluctant to give too free a hand to a man so enthusiastic and energetic as de la Beche.

The circumstances connected with the appointment of Dr. John Macculloch as geologist to the Trigonometrical Survey, and the preparation of his geological map of Scotland, which was not published until 1836, the year after his death, are outlined in a paper entitled "John Macculloch, F.R.S. and his Geological Map; an account of the first Geological Survey of Scotland" (V. A. Eyles, *Annals of Science*, **2**, 114–129; 1937). It appears that Macculloch's salary was to be £2 per day during the time he was at work, with an allowance of £1 a day for personal expenses, and 2*s*. for every mile he travelled. There was also an allowance of £90 per season for an assistant, but although no mention is made of the identity or the duties of an assistant, the pay was drawn for several years.

The travelling allowance gave rise to trouble with the Treasury, for in 1828 Macculloch charged for 7,764 miles of travel in 184 days. The auditors pointed out that, allowing for a journey from London to Glasgow, which accounted for 735 miles and four days, and for no work being done on Sundays, Macculloch must have travelled, on an average, 51–52 miles a day, which was, the report continues, "a rapidity of travel, which would hardly allow much time for scientific observation".

It would be unfair to the memory of a great man to refer only to this aspect of his work, for he was hard working and competent, and, as Mr. Eyles points out, in spite of the difficulties arising from a lack of good topographical maps, Macculloch's geological map of Scotland has stood the test of time. It became the basis of all subsequent geological maps of that country, and there are still areas of which little more is known than was recorded more than a century ago by that versatile Guernsey-born Scotsman.

F. J. N.

Science News a Century Ago

The Snake Nut Tree of Guiana

AT a meeting of the Linnean Society held on June 6, 1837, two communications were read from Robert Hermann Schomburgk (1804–65), who in 1831–35 explored British Guiana on behalf of the Royal Geographical Society. The first of these dealt with several new species of Orchideœ found in Guiana, and the second with the snake nut tree. The nut, he said, was the size of a walnut, and when the kernel was opened, and the membrane removed, there was an appearance of a snake lying with its body coiled up, the head, eyes and mouth being very distinct. From this appearance, by some singular analogy, it was employed as a remedy for the bites of snakes, for which it enjoyed a considerable reputation. The colonists were unacquainted with the mode of its growth as they only found it on the banks of brooks and rivulets after floods, but imagined that it grew on a creeper by the side, which explained the reason that it was found on the low islands and in these situations. Having been informed of the whereabouts of the tree, Schomburgk visited it, but it was not sufficiently far advanced for him to recognize the class and order to which it belonged. The tree was of the first magnitude, its branches dividing at a height of 40–50 feet. It contained nothing remarkable except the fruit, which was not known to possess any medicinal properties.

Schomburgk, who was born and educated in Germany, was Government Commissioner for surveying and making boundaries in British Guiana in 1841–43, establishing the 'Schomburgk line'. In 1844 he was knighted.

Vyse's Exploration of the Egyptian Pyramids

IN 1835–37, Colonel (afterwards Major-General) Richard William Howard Vyse (1784–1853) explored the pyramids of Egypt, and some of his discoveries were described in letters read to the Royal Society of Literature on June 8, 1837. The principal results of his exertions were the discovery of three large chambers in the Great Pyramid and the excavation of a remarkable mummy pit in its vicinity. The first of the newly opened chambers was 38 ft. 6 in. from east to west and 17 ft. 1 in. from north to south. This had been named the Wellington Chamber by Colonel Vyse, and he had had that illustrious name inscribed on its northern walls. The second chamber he had named after Nelson, and the third after Lady Arbuthnot, who was present at its discovery. The three chambers were above one another, and it was supposed their object was to lessen the superincumbent weight above the King's Chamber. A great quantity of drawings had been sent home to be engraved, including accurate sections of all the pyramids, and facsimiles of hieroglyphics in the newly discovered chambers.

The Royal Astronomical Society

THE last meeting of the session of the Royal Astronomical Society was held on June 9, 1837, when several papers were read. Baily, the president, who was in the chair, communicated a paper on the non-existence of the star called 42 Virginis, the insertion of which into the British Catalogue of Flamsteed he attributed to an error in computation. Baron Zach had given, in his zodiacal catalogue, a star which he called 42 Virginis, which, however, did not agree with the position given by Flamsteed, but what was very singular, this star also was not then found in the heavens.

Another paper was by Main, principal assistant at the Royal Observatory, on the position of the node, and the inclination of Venus. It appeared that Encke had altered the place of the node from the observations of the transits of 1761 and 1769, and this was found not to correspond with the best modern observations. Main therefore had undertaken the arduous task of determining these positions anew from observations made by Airy at Cambridge.

Premiums offered by the Zoological Society

IN the *Athenæum* of June 10, 1837, it was stated that the Council of the Zoological Society had determined to offer annual medals, or equivalent sums of money, by way of premiums for subjects connected with zoology. The premiums for 1837 were to be awarded for the following: (1) For importing either a pair of musk oxen, or a specimen of the hippopotamus, male or female; or a pair of the *Ornithorhynchus paradoxis*; (2) to the breeder of the greatest number of curassows in the year 1837; (3) to the importer of a male and female Indian pheasant, of a species not already alive in Great Britain; (4) to the breeder of the best specimens of Indian fowls in the year 1837; (5) to the breeder of the most rare or most interesting foreign quadruped in the year 1837; (6) for the best essay on the care and treatment of the species of the genus *Felis* in confinement.

University Events

ABERDEEN.—A capital sum has been given anonymously to the University for the foundation of a part-time lectureship on psychopathology. It is a condition of the gift that the lecturer shall not be an alienist and that the clinical work should be done at the Royal Infirmary. £500 has also been received from Lord Glanely for research in rheumatism.

CAMBRIDGE.—Dr. H. Hamshaw Thomas has been appointed reader in plant morphology; Dr. W. B. Lewis, of Gonville and Caius College, University lecturer in physics; Dr. H. Carmichael, of St. John's College, E. S. Shire, of King's College, University demonstrators in physics; and Dr. W. C. Price (Wales and Johns Hopkins), and Dr. E. A. Moelwyn-Hughes, of Corpus Christi College, University demonstrators in chemistry.

G. L. Clark, of Fitzwilliam House, has been elected to the Sheepshanks Exhibition for 1937.

It is proposed that a second assistant directorship of research in colloid science be established, and that the General Board be authorized to appoint in the first instance to this post Dr. J. H. Schulman.

The following have been approved for the degree of Sc.D.: B. H. C. Matthews, of King's College; R. S. Morrell, of Gonville and Caius College; G. C. Steward, of Gonville and Caius College; and L. R. Cox, of Queens' College.

LONDON.—The University enters upon its second centennium (the completion of its first hundred years was celebrated last July) with a student enrolment of approximately twenty-five thousand. The report recently presented by the acting principal on the work of 1936–37 gives the number of internal students as 12,734, and of these nine tenths were reading for degrees and diplomas, namely, in science (3,727), medicine (3,309), arts (2,957), engineering (1,351) and economics (1,001). Of the external students, some 11,000 in all, 6,779 entered for examinations, and of these nearly three fifths were receiving instruction in institutions in London (1,200) or elsewhere; two thirds of the remainder were prepared by correspondence courses and the rest wholly by private study. An indication of the world-wide extent of the university's contacts is to be found in the fact that the lecturers in the forty-nine courses of special lectures arranged by the Senate were drawn not only from the British Isles but also from Austria, Belgium, China, France, Germany, Holland, Hungary, Italy, South Africa, Sweden and the United States. The report chronicles a significant event in the field of physical culture: for the first time in its history, the University took part in an international athletic match, namely, between teams from the Universities and from boys' schools of Paris and London.

A Carpenter Medal with a money prize of the value of £20 in all will be awarded this year for work of exceptional distinction on statistical, genetic, comparative or experimental psychology including the functions of the cerebro-spinal system, for which a doctor's degree (other than the Ph.D.) has been awarded during the period of three years ending May 31, 1937. Applications should be made not later than June 10 to the Academic Registrar, University of London, from whom further information may be obtained.

Oxford.—At Encænia on June 23, honorary degrees will be conferred upon the following, among others:—D.C.L.: The Right Hon. W. G. A. Ormsby-Gore, Hon. R. H. Brand and Sir Herbert Baker. D.Sc.: Prof. Walter Nernst. D.Litt.: Dr. G. P. Gooch.

Prof. W. L. Bragg will give the Robert Boyle Memorial Lecture in the Museum at 8.45 p.m. on June 11. His subject will be, "The Crystallization Patterns of Alloys".

Societies and Academies

Edinburgh

Royal Society of Edinburgh, May 3.

H. H. Read: Metamorphic correlation in the polymetamorphic rocks of the Valla Field Block, Unst, Shetland Islands. Three metamorphisms under widely different physical conditions have affected the rocks of the western part of Unst. The mineral assemblages produced during each metamorphism in rocks of different compositions—pelitic, calcareous, siliceous, migmatitic, granitic and hornblendic—are correlated both isophysically and isochemically. It is concluded that in polymetamorphism the stability of an assemblage depends upon the bulk-composition of the rock, and that minerals cannot be considered apart from the rocks in which they occur.

J. Small: Quantitative evolution (2). Compositæ *Dp*-ages in relation to time. Using a geological time scale similar to that of Barrell, but with a longer Pliocene like that indicated by Urry (Nature, Feb. 20, p. 334), all the five average tribal *Dp*-ages of Compositæ are found to lie on or near a curve with the formula—$Dp.k+n.d.=t_k.2^n$; for Compositæ $k=0{\cdot}6$; $d=0{\cdot}9$; $t_k=1{\cdot}09375$ million years. From this bat curve, it is calculated that the free doubling period is approximately two million years. (3). *Dp*-ages in Gramineæ. The bat curve for Compositæ is applied to the grasses. The evolutionary sequences of *Dp*-ages in terms of time are found to be in almost complete agreement with the views given by Bews in his "World's Grasses".

W. Graham-Smith and T. S. Westoll: A new long-headed Dipnoan fish from the Upper Devonian of Scaumenac Bay, P.Q., Canada. During the summer of 1934, three specimens of a very distinct new Dipnoan were found at Scaumenac Bay, Quebec. These are described under the name *Fleurantia denticulata*, gen. et sp. nov. The species differs from other Dipnoans in having an extreme elongation of the snout. The dentition consists of a series of large conical teeth and a granulation of smaller teeth. The snout-elongation is shown to be probably correlated with the development of a sectorial dentition and with corresponding feeding-habits.

W. J. Hamilton: The early stages in the development of the ferret: the formation of the mesoblast and notochord. The mesoblastic cells arise from the ectoderm at the site of the future primitive streak. The cells spread anteriorly and laterally as two sheets which meet at the anterior part of the embryonic disk. Henson's Knot does not appear until the primitive streak is well formed and it is separated by a narrow neck from the anterior extremity of the streak. From the anterior part of Henson's Knot the archenteric process with the archenteric canal develops. The cells of the archenteric process become intercalated in the yolk-sac endoderm and form the archenteric plate which terminates anteriorly in the prochordal plate.

W. O. Kermack and A. G. M'Kendrick: Some distributions associated with a randomly arranged set of numbers. In a previous paper, certain frequency distributions associated with the occurrence of sequences or 'runs' of continuously increasing or decreasing numbers in a long series of randomly arranged unequal numbers, have been made use of as the basis of a test of randomness. The general mathematical theory of the distributions of such runs is now discussed for (*a*) an infinite linearly arranged set, (*b*) a finite linearly arranged set, and (*c*) a finite cyclicly arranged set of numbers. The distributions are in general obtained as solutions of difference equations, and expressions are given for the generating functions of these frequency distributions.

K. B. Lal: Immature stages of some Scottish and other Psyllidæ. In the course of previous researches (*Trans. Roy. Entom. Soc.*, 83; 1934) the author realized the difficulty of associating the immature stages of the thirteen species discussed with their particular species. Full descriptions of these stages are therefore given for each species, and the various characters important in distinguishing the species are clearly and carefully illustrated.

D. S. Raitt: The benthic Amphipoda of the north-western North Sea and adjacent waters. Some 3,000 amphipods secured over the Scottish area by Peterson grab and from haddock stomachs were identified and their distributions studied. When division of the North Sea by the 40 and 100 metre depth contours was adopted, the rates of occurrence of the order in the three zones formed was 3 : 2 : 1.

The species, and their abundances, also varied from zone to zone. The genus *Ampelisca* was outstandingly abundant, however, forming 55 per cent of the grab material, with the single species *A. brevicornis* in complete domination, forming 25 per cent of the total grab captures.

Capetown

Royal Society of South Africa, March 17.

F. G. Cawston: Some characteristics of *Bulinus* and *Physopsis*. Considerable variation is observed in several species of *Bulinus*, so that the various shells may resemble one another very closely. *Physopsis africana* Krauss is readily distinguished by its relatively constant columella. It does not adhere so firmly to floating vegetation as allied shells; but, unlike the operculated shells, is a favourite food for ducks.

W. E. Isaac: Studies of South African seaweed vegetation. (1) West coast from Lambert's Bay to Cape Point.

J. C. Smuts: (1) The climate and stone implements of Rooikop. (2) Past climates and pre-Stellenbosch stone implements of Rietvlei (Pretoria), and Benoni.

F. E. Fritsch and F. Rich: (12) Algæ from the Belfast Pan, Transvaal. Belfast Pan is situated in the Transvaal Highveld, 120 miles due east of Pretoria, in a depression on top of a kopje. Samples of the algal vegetation were collected by Dr. E. M. Doidge in 1909, 1913, and 1924. It is remarkably rich in desmids, at least 143 species being present. The wealth of new varieties and forms may perhaps be correlated with the isolation of the Pan. Conjugation was seen in forty species.

M. R. Drennan: The Florisbad skull and brain cast.

B. V. Skvortzov: Contribution to our knowledge of the fossil diatomaceous flora of South Africa. (1) Fossil diatoms from distomaceous limestones from pan near Franzenkop and Prieska, Cape Province.

Cracow

Polish Academy of Science and Letters, March 8.

D. Doborzynski: Measurements of the dielectric constant by means of ponderomotive forces (1), (2) and (3). Discussion of the limitations of the method. Application to quartz crystals.

Th. Banachiewicz: The calculation of determinants.

M. Kamienski: The appearance of the Wolf I comet in 1933–34.

L. Marchlewski and W. Bednarczyk: The absorption of ultra-violet rays by certain organic substances (43). Results for lævulose, glucose and some sugars.

L. Marchlewski and Mlle. R. Grunbaum: Absorption of ultra-violet rays by certain organic substances. (44) Results for substances of importance in physiology. Also the spectra of the three isomeric nitranilines. (45) Phenanthrene derivatives.

L. Marchlewski and W. Bednarczyk: (46) Data for 8-hydroxyquinoline, for unsaturated acyclic alcohols, kiketopiperazine, benzophenone and *p*-toluyl-2-benzoic acid.

L. Marchlewski and J. Dabrowski: Studies on cellulose from flax. Comparative studies of cellulose from flax and from cotton.

B. Skarzynski: Spectrographic studies of the processes of enzyme hydrolysis of saccharose and of maltose.

A. Kocwa: New syntheses of compounds of the pyrazoquinoline type.

L. Chrobak: Analyses of the minerals formed on silver coins of the fifteenth century.

J. Dembowski: Contribution to the problem of instinct.

W. Swienty: The earliest stages of development of the blood vessels in the wing of the fowl.

Geneva

Society of Physics and Natural History, February 18.

K. H. Meyer and J. F. Sievers: The appearance of rubber-like elasticity in selenium. Grey amorphous selenium, heated to between 70°–79° C., acquires an elasticity recalling that of india-rubber, due to the formation of long directed molecular chains.

J. Weigle and H. Saini: The transformation of heavy ammonium chloride. The authors have studied heavy ammonium chloride under X-rays, and have found a sudden change of dimensions of the lattice in the neighbourhood of $-22°{\cdot}5$ C. instead of at $-30°$ C. as with ordinary ammonium chloride.

P. Dive: The geometry of the rotating disk in the Einstein system. The author maintains that the natural geometry of rigid bodies involved in the rotation of the disk is Euclidian.

G. Tiercy: A differential equation met with in a problem of aerodynamics. This concerns the study of the wind. It is found that the equation in question can be used with difficulty.

P. Rossier: (1) The relation between the brightness, colour index and effective wave-length of a star. The brightness is proportional to the colour index. The author generalizes this property in the case of receivers with non-concentrated sensibility. (2) The mean colour index of stars in the neighbourhood of bright stars. This index varies linearly as a function of the guide star. (3) An orthochromatic plate, the sensibility maxima of which have very unequal acuteness. For the Tizian plates, figures for acuteness are found of 41·6 and 940, the ratio of which is the highest known up to the present.

Sydney

Royal Society of New South Wales, April 1.

E. Booth: Some tests of thermal constants of glass bricks. Glass bricks are now regularly used for structural purposes; the type provided to the author (by the Australian Window Glass Pty. Ltd.) were hollow and of external dimensions 16·5 cm. by 16·5 cm. face and 10 cm. depth, the thickness of the glass walls being about 0·8 cm. The faces were patterned both inside and outside (crossed cylindrical lenses) on both fronts so as to prevent direct vision through the blocks, and were constructed in two moulded parts, sealed together by an aluminium solder at 1,400° F. so that the hollow was a partial vacuum, being closed at atmospheric pressure at a temperature of 1,100° F. Tests on thermal transmission (apart from radiation) were made between one face at room temperature and one at 0° C., suitable and satisfactory insulating precautions being adopted; the method is described. The result for a block is 1·8 gm. cal./min./cent./deg. per block, being 0·39 gm. cal./hour/sq. cm./cent./deg. face difference.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, June 7

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Peter Mott: "A Survey of West Greenland".

Tuesday, June 8

WARBURG INSTITUTE, at 5.30.—Miss Violet Alford: "Carnival and Saturnalia".*

Thursday, June 10

CHADWICK PUBLIC LECTURE, at 5—(at the Chelsea Physic Garden, Swan Walk, S.W.3).—H. Gilbert-Carter: "Plants in Health and Disease".*

Friday, June 11

UNIVERSITY OF OXFORD, at 8.45—(in the Museum).—Prof. W. L. Bragg: "The Crystallization Patterns of Alloys" (Robert Boyle Memorial Lecture).

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

LECTURER IN MECHANICAL ENGINEERING in the Chesterfield Technical College—The Clerk to the Governors (June 7)

ASSISTANT CIVIL ENGINEERS in the Directorate of Factories, War Department—The Chief Superintendent of Ordnance Factories (Advt No 140), Royal Arsenal, Woolwich, S E 18 (June 8).

LECTURER IN GEOGRAPHY in Birkbeck College, Fetter Lane, E C 4—The Secretary (June 10).

ASSISTANT (grade II) in the External Ballistics Department, Ordnance Committee, Royal Arsenal, Woolwich, S.E 18 (June 11).

ASSISTANT MASTER IN CHEMISTRY (subsidiary biology) in the South-East Essex Technical College, Longbridge Road, Dagenham—The Clerk to the Governors (June 12).

HEAD OF THE DEPARTMENT OF MATHEMATICS AND PHYSICS in the Polytechnic, Regent Street, London, W.1—The Director of Education (June 12).

LECTURER IN METALLURGY and ASSISTANT LECTURER IN ENGINEERING in the Swansea Technical College—The Director of Education, Education Offices, The Guildhall, Swansea (June 12)

HEAD of the Electrical Engineering and Physics Department of Coventry Technical College—The Director of Education, Council House, Coventry (June 12).

LECTURER IN MECHANICAL ENGINEERING in the Merchant Venturers' Technical College, Bristol—The Superintendent (June 14).

FISHERY OFFICER in the Fisheries Department of the Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S W.1—The Secretary (June 14).

ASSISTANT MASTER to teach Mathematics and Science in the Cambridgeshire Technical School—The Education Secretary, Shire Hall, Cambridge (June 14).

MANAGER (CIVIL ENGINEER) to the West Cumberland Industrial Development Company, 30, Roper Street, Whitehaven—The Secretary (June 15).

LECTURER IN ELECTRICAL ENGINEERING in King's College, Strand, London, W.C 2—The Secretary (June 15).

ASSISTANT LECTURER IN APPLIED MATHEMATICS in the University of Liverpool—The Registrar (June 18).

ASSISTANT KEEPER on the Higher Technical Staff of the Mechanical Engineering Division of the Science Museum, South Kensington, S.W 7—The Director (June 21).

LECTURER IN MATHEMATICS in the University of Sheffield—The Registrar (June 22).

LECTURER IN EXPERIMENTAL ZOOLOGY in the University of Liverpool—The Registrar (June 23).

RESEARCH CHEMIST at the Indian Tea Association Experimental Station, Tocklai, Assam—The Secretary, Indian Tea Association, 21 Mincing Lane, London, E C.3 (June 25)

HULME LECTURER IN PHYSIOLOGY in Brasenose College, Oxford—The Principal (June 26)

PROFESSOR OF ECONOMICS in Raffles College, Singapore—The Secretary, Universities Bureau of the British Empire, 88A, Gower Street, London, W.C 1 (June 30).

VETERINARY RESEARCH OFFICER (investigation of contagious bovine pleuro-pneumonia) in Kenya—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, London, S W.1 (June 30).

LECTURER IN MINING in the South Wales and Monmouthshire School of Mines, Treforest—The Director of Education, County Hall, Cardiff (June 30).

PROFESSOR OF BOTANY in the University of Sydney, New South Wales, Australia—The Registrar (September 15)

ASSISTANT ENGINEERS, ENGINEERING ASSISTANTS AND JUNIOR ENGINEERING ASSISTANTS in the Ministry of Transport, Whitehall Gardens, London, S.W.1—The Establishment Officer

ASSISTANT TEACHER OF ELECTRICAL ENGINEERING AND ASSISTANT TEACHER OF MATHEMATICS in the Acton Technical College—The Secretary to the Education Committee, 10 Great George Street, Westminster, S.W.1.

TEACHER OF MECHANICAL ENGINEERING in the Rochdale Municipal Technical School—The Secretary.

ROAD ENGINEER in the Public Works Department, Somaliland—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1.

PROFESSOR OF MINING in the University of Peiyang—The Universities' China Committee, 91 Gower Street, W.C.1.

ENGINEERING INSTRUCTOR in the Kingston Technical School, Jamaica—The Crown Agents for the Colonies, 4, Millbank, London, S.W.1.

Science and Peace

IN the remarkable differences between the world to-day and that of a century ago, the good changes and the evil are in the last resort due mainly to the use or misuse of scientific discovery. Men of science are, of course, not the sole agents in the transformation; their work is applied by others, under the direction of industrialists and Governments, for private gain or for the public good as judged by statesmen and administrators.

Until lately, the average man of science was scarcely more interested in the uses to which his work was put than is the ostrich in the fate of the eggs that she lays. There will always be scientific workers whose interests seem far removed from ordinary human affairs; but the activities of an increasing proportion of men of science are closely linked with social purposes. Many of these can work with good heart in full confidence that the fruits of their labours increase the health and happiness of mankind; but there is a darker side to the picture, since through science the horrors and waste of war have been greatly intensified. The result is that some people think that the only way to save civilization is to suppress further advances in scientific knowledge.

Responsibility for the deplorable growth of destructive forces cannot, however, be accepted by men of science except as citizens. Throughout recorded history there has been war, and the captains and the kings have always sought to increase their military strength by the inventions and the science of their time. The change in our day is not fundamental, but lies only in the much greater effectiveness with which the old purposes are pursued, through the application of modern scientific method and resources. From the military point of view, organized scientific effort meets with the same astonishing success as when applied to peaceful ends; but the result for mankind is to extend enormously the burden of fear and the potential human suffering through war. Indeed, ever since the Great War, this suffering has been not only potential but actual, as recently in Abyssinia and now in Spain.

The Founder of Christianity asked from the Cross forgiveness for those who set Him there, "for they know not what they do". The cross of war laid upon mankind is due, like that other Cross in Jerusalem, to the moral and intellectual frailty of man—to the craft of a few who are deeply evil; to the folly and weakness of others among the great, who are not lacking in goodwill; to the passions and tumult of the multitude. Perhaps the share of science in this modern crucifixion may be compared with the work of the soldiers who then drove in the nails and raised high the crosses.

Were these soldiers worse than other soldiers? Was not the Government and nation that made them soldiers, and assigned their tasks to them, more responsible than they for that evil? In like manner, are those scientific workers who are directly working for military ends to be regarded as worse than other men of science? Surely the chief responsibility lies with the community at large; and in proportion to his single-minded simplicity, the militarized man of science, like the common soldier, is to be honoured for the faithful following of his vocation.

Many minds, however, cannot find rest in simple obedience to authority, in simple national patriotism. The principle of the settlement of disputes by war is increasingly questioned by the mind and conscience of man, and not least among men of science. Many fair-seeming bubbles have been burst, and recognized for the hollow, puffed-out things that they are: the famous Oxford resolution on fighting for king and country was symptomatic of this. Of course, if Britain should become involved in war, the youth of Oxford would fight; but among them and the rest of the soldiers there would be a larger proportion than in any previous war, who from the outset realized the futility, the colossal folly of war. Even in Germany, with all its unchallenged internal propaganda, it is not too easy to resurrect the old 'Heldentum' nonsense, which many German ex-soldiers hoped had been cast into limbo for ever.

Already in the time of the Great War the prostitution of science to warfare was deeply felt by many British men of science, some of whom refused altogether to participate either as soldiers or as scientific workers. The same attitude would again be taken by many, should we be cursed by another war; even in the present time of uneasy peace, the activity in rearmament is renewing in the minds of many men of science the same tension of feeling, the same problems of conscience. Such scruples, sincerely held, claim at least the same measure of public consideration and respect as they received in Britain during the Great War. For such men there is often no choice whether they shall or shall not refuse war-service, scientific or otherwise; like Luther on a famous occasion, "they can no other".

Most men of science will know outstanding examples, among their colleagues, of men who so refused in the Great War, and, by our national wisdom, were spared the penalties that in other countries might have led to their death, by direct act or by obloquy and torment leading to suicide. Many such men have, in the years since then, rendered distinguished service to the community; their work, and that of many lesser men who followed the same course, has enriched the nation, and been rendered with loyal recognition of the toleration extended to them by their fellow-citizens during a time of great national stress.

To the main body of men of science, however, military preparations, and scientific co-operation in them, seem in the existing state of the world a necessary, though regrettable, measure. It is important that there should be mutual respect and understanding between this majority, and their colleagues who are extreme pacifists—the larger group standing by the minority, to protect them against victimization, and the minority co-operating wherever possible with their fellows, and respecting in them their loyalty to their duty as they perceive it.

Should this duty end, however, with the performance of their special technical functions? Does there not rest upon men of science as a body a responsibility for the promotion of peace, and peaceful methods of international adjustment, beyond that which already attaches to them as citizens? Their special outlook, education, training and gifts seem to involve this.

In the first place, scientific workers are better able than most men to reflect with knowledge upon the evolution of man, and to realize what immense conquests have already been made over ignorance, weakness and evil. They can in some measure review the progress of man in social organization, and envisage great improvements still to come, realizing that even to-day unity in government may be maintained, as in Canada, despite enduring differences of race, religion, language and traditions among the people. They know that wider loyalties can develop and become paramount over a hierarchy of narrower loyalties. They have, therefore, ground for good hope, since so much has been achieved by steps largely unconscious or groping, that far more can yet be done by conscious and well-chosen effort.

Secondly, they have long been accustomed to international co-operation, without which the state of science itself would still be relatively primitive. They can, therefore, well judge how fruitful would be the adoption of a similar policy in the social and economic sphere, even if military budgets continued as now; but such co-operation would also remove many of the chief causes of international mistrust, and enable much of these budgets to be diverted to happier uses.

Furthermore, their whole professional activity contrasts strongly both in method and success with the military method of settling international problems. The military method is inherently ill-designed to yield good results. Men of science know that the judgment is warped by bitter passions such as prevail in war, and that difficult problems are best attacked by earnest, dispassionate search after understanding and truth, with prolonged patience and resource; they have therefore a special duty to urge the application of these methods to international problems. To attempt to solve the problems by military force, or the threat of it, is to hazard our whole well-being, with no certainty that the better cause will prevail or the best solution be arrived at: on the contrary, with the certainty that whatever side gains the victory, those who bear the suffering—nowadays the majority of the people—will never reap a reward that will compensate them for their travail and sorrow.

Medical men form a group among scientific workers who have particular reason to hate war and to seek after peace: the wholesale maiming, poisoning and starvation involved in war is in extremest contrast with their lifework for the maintenance of health and the alleviation of human suffering. A campaign to arouse the interest of the medical profession in the promotion of peace has lately been launched, with much devoted work and considerable success: similar efforts have been in progress at Cambridge, Oxford and elsewhere, among scientific workers of other kinds. During the recent National Peace Congress in London, among the several Commissions which considered special aspects of the peace question was one on science and medicine, reference to the proceedings of which appears elsewhere in this issue (p. 993). It is hoped that, as a result of the meetings of this Commission, local groups of scientific workers will be formed in many other places, for the promotion of peace by study, research and propaganda.

We do not overlook the fact that urgent reasons can be given in favour of the present British rearmament, or that there is little likelihood that our vast military preparations will be devoted to selfish aggression. But it cannot be denied that a Europe armed to the teeth will be an unstable Europe, living under the shadow of fear that some spark may produce a disastrous conflagration. What we suggest is that some part of this great effort and expenditure on rearmament would be more fruitful for the peace of Europe and the world, if employed in other ways. The greater part of that expenditure might, indeed, be saved by a more active policy of international co-operation and appeasement.

The main argument against such proposals is that our very safety is threatened by other well-armed nations, so that rearmament is essential for the defence of our lives and ideals. We know ourselves that our intentions are wholly non-aggressive, but can we expect the rest of Europe to welcome a *pax britannica*, imposed on 'the lesser breeds' by means of our great national wealth? Surely the only kind of peace likely to endure in Europe is one that is corporately maintained by the community of European nations, whose instrument of co-operation is ready at hand in the League of Nations The best means to achieve this cannot now be discussed here, but a determined effort, and indeed lead, in this direction seems incumbent on the British Government to assist movements for the promotion of international peace and thus avoid the impression that recent activities are solely concerned with military measures for national defence in case of war.

Science and Social Responsibility

What Science Stands For

By Sir John Boyd Orr, Prof. A. V. Hill, Prof. J. C. Philip, Sir Richard Gregory, Sir A. Daniel Hall, Prof. Lancelot Hogben. Pp. 132. (London: George Allen and Unwin, Ltd., 1937.) 5*s*. net.

THE future historian of science will not fail to chronicle that the early part of the twentieth century was notable for the gradual emergence of a social conscience among scientific men, which, he will aver, was greatly stimulated by the mis-use of certain scientific discoveries for inhuman ends (for example, poison gas against civilians), and by the recognition that extending application of science to industry did not appreciably improve the status or the prospects of the working classes.

The effects of the so-called impact of science upon social life have for long been made prominent in the columns of NATURE, but it is only of late that they have engaged general attention, for example, at recent meetings of the British Association. Incidentally, the word 'impact' seems ill-chosen, for science has been penetrating, not merely impinging on, the material social fabric for at least a century. At last year's meeting in Blackpool, some notable addresses were given on this theme, of which five are reproduced in the volume before us. Covering as they do a diversity of subjects, the choice of an apt title could not have been an easy one; hence the use of the woolly preposition-verb 'stand for'. If the question implicit in the title had been put to T. H. Huxley, his reply would have been immediate: "For intellectual honesty and the fearless pursuit of truth". Pasteur would have said that science stands primarily for the alleviation of human suffering; Dr. Herbert Dingle that it stands for the co-ordination of sense observations; and a modern political dictator would see in science merely means of controlling the popular will. Sir Daniel Hall, in his vigorous and outspoken address on "Knowledge and Power", sees in science the means to enrich life, and he is as insistent on the non-material benefits as on the material. Sir Richard Gregory, writing on "Cultural and Social Values", elaborates this view, and strongly emphasizes the part played by science in developing the human mind, intellectually, æsthetically and morally.

Although the material fruits of scientific discovery are by no means ignored—Sir John Orr writes on nutrition and Prof. J. C. Philip on the ubiquity of chemistry—the ethical and educational issues which they raise, to wit, social responsibility for the applications of science and the place of science in education, are treated with the prominence they deserve. Sir John Orr thinks that the State has a moral responsibility for seeing that all its citizens obtain the food which health demands; and all the authors would agree that a one-sided training in letters, languages, or art is a very poor preparation for a modern statesman or ruler of men. A background of science is also essential for adapting our antiquated economic theories to modern actualities; and for encouraging the habit of acting on reason instead of on emotion. As Sir Daniel Hall says, "Everywhere we see individuals and nations responding to crude emotional impulses. . . . One function of an education based upon Science is to . . . teach boys and girls in their earliest formative years that all the world over men and women are . . . very much alike. Diversity exists among the individuals, and civilisation largely consists in giving that diversity full play". Prof. L. Hogben, the Sir Galahad of modern progress ("with manly grace, yet maiden meekness in his face"), demands nothing short of a transvaluation of all educational values.

After reading these interesting and valuable addresses, one is more than ever convinced that in real education for a full individual life and for good citizenship—the two are not incompatible—lies the one remaining hope for civilized humanity. As H. G. Wells so well put it: history is coming more and more to be "a race between education and catastrophe". E H. T.

Experimental Embryology

Experimentelle Beiträge zu einer Theorie der Entwicklung

Von Hans Spemann. (Deutsche Ausgabe der Silliman Lectures gehalten an der Yale University im Spätjahr 1933.) Pp. viii+296. (Berlin: Julius Springer, 1936.) 29.60 gold marks.

IN this book, Prof. Spemann has collected the main results of his life-long series of experiments on animal development and of those of his school, and he takes stock of the present position in regard to the problems of form-production. He is careful to warn his readers that this is not a text-book, but a record of a line of scientific thought pursued with the help of experimental methods. It is all the more welcome, for his acute analysis and logical progress from question to (experimentally provided) answer are most acceptable and helpful as guides through a field where isolated data are legion, but general principles few.

One of the most interesting of these principles is that known as 'double assurance'—the existence of two mechanisms which function independently to produce one and the same structure. Advanced to cover the case of the operculum of Anuran larvæ which can be perforated by an arm-bud and also without an arm-bud, the notion of double assurance has recently fallen out of favour since the realization that the perforation is brought about by other structures (the atrophying gills). But in regard to the lens, which in certain frogs can be induced by the eye-cup but can also develop without an eye-cup, Prof. Spemann shows that a duplicity of formative methods undoubtedly exists: one involving diffusion of a presumed chemical substance from the eye-cup, the other involving 'determination' *in situ* of the lens before closure of the neural folds. The question how such independent sets of processes are correlated and initiated in ontogeny, or have evolved in phylogeny, is not the least of the fascinating problems which this work raises. Special attention is devoted to fundamental definitions such as 'potency' and 'determination', and also to the results of biochemical analysis of the mode of action of the organizer.

Perhaps one of the most important sections of Prof. Spemann's book is that in which he reviews the hypotheses of 'gradients' and 'fields' that have been advanced to account for certain aspects of development. These he has difficulty in accepting; in particular: that the graded rates of tissue-activity postulated by the gradient hypothesis can be the specific causes of the movements of cell-groups that result in gastrulation and form-production; that the long adaptive history of the presence of certain highly differentiated structures in the head-region of animals can be condensed developmentally into a matter of differential oxygen supply to different parts of the egg; that quantitative differences of rate of activity can result in qualitative differences of structure; and so on.

To consider these objections here would take too long, and it must suffice to direct the reader's attention to them. Some of them can probably be met; for example, it seems that yolkless cells cleave faster than yolk-laden cells, not directly because of greater activity of their protoplasm, but indirectly because the greater activity has oxidized and prevented the deposition of yolk in them. For the rest, it is probable that Child and his followers, in wanting to avoid appealing to *chemical* localizations to account for the *earliest* phases of differentiation, and being therefore driven back on to *physical* regional differences, have assumed too lightly that these differences are manifested in rates of metabolism or protoplasmic activity. It is, of course, the peculiar position of the gradient hypothesis that it is the only concept so far framed which covers the outstanding phenomena of development and regulation, but that it is exceedingly difficult to devise or perform experiments to prove its validity satisfactorily.

Without doubt, however, the greatest debt in which Prof. Spemann has placed his readers is for the admirably clear, and, it may be added, delightfully sympathetic, account he has given of the discovery and properties of the amphibian organizer. Many other authors have written about it in their books, and now at last here is a book dealing with these fundamentally important matters with the first-hand knowledge of their discoverer. The Silliman Lectures, on which the book is based, were delivered in 1933; but the book is brought completely up to date and includes the advances made during the past few years. G. R. DE BEER.

German Physics

Deutsche Physik
Von Philipp Lenard. In 4 Bänden. Band 1: Einleitung und Mechanik. Pp. xv+249. (München: J. F. Lehmann, 1936). 10 gold marks.

PROF. P. LENARD is known to fame in two capacities, as the great experimenter whose work on phosphorescence and electronics is fundamental for modern physics, and as the politician, the stalwart fighter against the Jewish evil, of whom Herr Rosenberg has said: "As a thinker, however, Professor Lenard has taught that all knowledge is not the same, but that souls of alien race produce bodies of knowledge of a quite different spiritual content". The present book, which is the first of a series designed to present the elements of physics to young students, shows him likewise in two capacities, as a profound political thinker and patriot on one hand, and as physicist on the other. The two are spatially separated, the one activity being confined to the preface and introduction and having, apparently, very little influence on the rest of the book, which has something in common with the excellent little work of the non-Aryan Warburg.

The preface is a clear exposition of Prof. Lenard's views on the harm done to physics by the Jewish people. The author states that every race has its own kind of physics: in the past there was a physics of the Arabs; to-day one can perhaps speak of a physics of the Japanese. There is no Negro physics, but recognition of the fact that there is a Jewish physics has been delayed simply because Jews write not in one language, but in many. "Jewish physics is then, a delusion and a sign of degeneration from the fundamental Aryan physics. It was necessary to stress this here with emphasis, for only when the fundamental opposition between Jewish and Aryan physics has become clear can the full appreciation of the value of the latter come into being again after having been lost so long." Einstein's theory of relativity is cited as particularly pernicious, as is also the Jewish division of physics into classic and modern, a piece of trickery designed to delude the German student. The preface, in fact, shows Prof. Lenard's competence in a field in which he is now an acknowledged master, for he has been entrusted with the task of reporting upon the question "Jewry in Science" for the Reichsinstitut für Geschichte.

The book itself consists of an introduction and a treatise on mechanics: it is being followed by three other volumes, dealing with the rest of physics. In the introduction, Prof. Lenard insists that all natural laws are simple, and that for an understanding of the fundamentals of physics very little mathematics is necessary. He shows himself particularly skilful in expounding the laws of mechanics, including such matters as the dynamics of rotating bodies, with a minimum of mathematical analysis: even those students who have mastered the conventional exposition in the ordinary text-books of rigid dynamics will probably find that Lenard's method of presentation helps them to realize what it is all about. It is, however, hard to understand why the editor of Heinrich Hertz and the admirer of Maxwell should speak as deprecatingly of theoretical and mathematical physics as does Lenard. He is probably thinking on one hand of those physicists who conceal their lack of real understanding behind a mist of formulæ, and on the other hand of Faraday, who discovered basic quantitative laws without any mathematical knowledge; but there are theoretical physicists who discover new truths, while Faradays cannot be expected even once a generation. Lenard's book shows how far a man with a real grasp of physical laws can go without mathematics, how clearly many fundamental matters, even the elements of hydrodynamics, may be expounded almost without symbols. It is the work of a great lecturer and teacher. At the same time the simplicity is sometimes a little misleading—to say that "the measure of inertia is called mass. This is the definition of the conception 'mass'" is scarcely a fair solution of the difficulty.

The book is in the best German tradition, as exemplified, for example, by Riecke, from whose book some of the illustrations are, apparently, taken. It does not touch upon recent work, but limits itself to physics as known at, say, the end of the past century. This is possibly not at all a bad thing in a book intended to ground the student in the really fundamental parts of physics; but at the same time the interest could have been widened by reference to some more recent matters, such as the lift of an aeroplane wing in the section on hydrodynamics.

As a record of the methods of one who, besides being an investigator of the first rank was also one of the best teachers of his time, the book has a claim on the attention of all who have to present the facts of physics, German or even non-Aryan, to the student.

E. N. DA C. A.

International Co-operation in Telephony

Comité Consultatif International Telephonique (C.C.I.F.)

Proceedings of the Xth Plenary Meeting, Budapest, 3rd–10th September 1934. Translated into English by the Technical Staff of the International Standard Electric Corporation. Pp. 660. (London: International Standard Electric Corporation, Ltd., 1936.) 25*s*. net.

IT is quite impossible in a short review to give an adequate account of the material, highly compressed and specialized in scope, which appears in the present volume of 660 pages. For the information in the field covered, that of telephonic communication between countries, it provides a bargain for those who can understand. There is so much that it takes the translators some two years to turn the five French volumes of the original into one volume in English. A detailed discussion is therefore not called for, especially since the material is not the work of individuals but of a large number of committees, the members of which may be located in several countries and do their work through the post.

The important thing about the Comité Consultatif International Telephonique (C.C.I.F.), which deals with telephony, and its parallel organizations, the C C.I.T. and C.C.I.R., which deal with telegraphy and radio respectively, is that they form an excellent example of what can be achieved internationally if the problem to be solved—here telephonic communication at the lowest cost and with the highest speed—can be stated clearly and given to investigators who are prepared to find a solution which is acceptable to the majority. The interesting thing about the system is that it has no power of compulsion on its members to carry out any instructions. It sets up a sub-committee to report on the data of a particular aspect of the general problem; the report may say that research must be done, and this is allocated to the particular telephone authority which has the facilities for carrying it out. When this is done and further considered, the C.C.I.F. makes its recommendations, and it is up to the participating administrations to carry out these recommendations so far as is desirable at the time in order to co-operate with similar organizations in other countries.

As contrasted with the world of politics, the countries lose little time in adopting recommendations for the improvement in international telephony. Further, the principles adopted by the C.C.I.F. soon find themselves prevalent in the domestic sphere of the individual countries, since for telephony the greatest measure of uniformity in practice makes for greater general effectiveness in what we now regard as the indispensable method of communication. If engineers were given other problems within their competence to solve, the world would be a better place.

L. E. C. H.

Flora of West Tropical Africa

the British West African Colonies, British Cameroons, the French and Portuguese Colonies south of the Tropic of Cancer to Lake Chad, and Fernando Po. By Dr. J. Hutchinson and Dr. J. M. Dalziel. Prepared at the Herbarium, Royal Botanic Gardens, Kew, under the supervision of the Director. (Published under the authority of the Secretary of State for the Colonies.) Vol. 2, Part 2. Pp. 293–651. (London: The Crown Agents for the Colonies, 1936.) 8*s*. 6*d*.

The publication of the second part of vol. 2 completes this "Flora". The part contains the account of the Monocotyledons, which are represented by thirty-five families. The arrangement, as in the previous parts, follows Dr. J. Hutchinson's "Families of Flowering Plants". An artificial key to the families which are dealt with in this part is provided, and an index to families, genera and synonyms contained in the entire work occupies forty-three pages at the end. A short account of the principal vegetational types, accompanied by a map, is given. The illustrations, many of which occupy full pages, are by Mr. W. E. Trevithick and Miss S. Ross-Craig.

The most important family from the economic point of view is the Gramineæ, the key to the tribes and genera of which is by Mr. C. E. Hubbard. 137 genera, and 503 species of grasses are included. The account of the Orchidaceæ is by Mr. V. S. Summerhayes and is of especial interest as Schlechter's classification of the Angræcoid genera is used for the first time in any flora. The remaining families have been dealt with by Dr. Hutchinson, with the exception of one or two genera: *Cyperus* Linn. by Miss E. A. Bruce, *Pycreus* Beauv. with Mr. B. L. Burtt, and *Sorghum* Pers. with Mr. J. D. Snowden.

The number of new species is considerable, whilst many names published by Dr. A. Chevalier without description have been adopted, and will be validated by Latin diagnoses in future numbers of the *Kew Bulletin*.

The accounts of certain families such as Zingiberaceæ, Marantaceæ, and Palmæ have suffered from the imperfect nature of the specimens which were available, whilst the paucity of the material of a number of the species is at once noticeable on glancing through the pages: many have only once been collected within the area covered.

Commonwealth Bureau of Census and Statistics, Canberra

Official Year Book of the Commonwealth of Australia. No. 29, 1936. Prepared by Dr. Roland Wilson. Pp. xxxii + 1015. (Canberra: Commonwealth Government Printer, 1936.) 5*s*.

This useful yearbook follows the same arrangement and embraces the same scope as previous issues: in statistics and to a less extent in description it gives a full account of nearly every aspect of Australian life, with further chapters on the territories of the Commonwealth including Papua, New Guinea and Nauru. History also finds a place in the detailed chronological table of events and a full reprint of the Commonwealth Constitution Act. Two excellent features are notable in the statistical matter: one being the comparable figures for other countries, and the other the figures for recent years in the Commonwealth.

As usual in every issue, there are certain distinctive features. Vital statistics, which are always treated fully, this year include analyses of the causes of death and also details of the dwellings of the population at the time of the census. There is also a special article on Australian population mortality.

The list of books and other publications dealing with Australia has been revised and is classified under subject headings. Maps show the distribution of rainfall and the location of the various artesian basins.

Mercury Arcs

By Prof. F. J. Teago and J. F. Gill. (Methuen's Monographs on Physical Subjects.) Pp. vii + 104. (London: Methuen and Co., Ltd., 1936.) 3*s*. net.

This little monograph formed the basis of a course of lectures on design given at the University of Liverpool. The subject of the conversion of alternating to direct current is very much to the front at the present time. The crystal detector for converting the rapidly alternating currents employed in radio transmission work, into direct current, so that they make an audible signal in the telephone, is an example of their use. Liquid rectifiers can be used for converting an alternating current into a direct current, so that the A.C. supply can be used to charge an accumulator. This is a useful practical application. Copper oxide valves having unilateral conductivity are much employed for handling the large outputs used in industry. The introduction of the A.C. grid in Great Britain has also introduced an ever developing demand for these electrical valves.

Some engineers may think that too many mathematical theorems are given in this book, but examination shows that they are simple and easy to understand, and as a rule they explain very satisfactorily some of the physical phenomena.

Control of Electrical Motors

By Paisley B. Harwood. Pp. vii + 390. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 22*s*. 6*d*. net.

Every year many thousands of motors are used for driving machinery. Each of these motors requires a controller of some kind. A simple manual starter might suffice for a small fan, but for the control required for a newspaper press something much more complicated has to be provided. Some engineer has to specify the duty of the controller required and someone else usually has to design and build it. In addition, it has to be installed and workmen trained to operate it. This book describes the working characteristics of the various kinds of motors and explains how these characteristics can be used for control purposes. Problems frequently encountered such as motor acceleration, dynamic braking and 'resistor' design are discussed fully. This book is easy to understand, and will be found useful by both engineers and operators.

Water-Power in the United States*

By Dr. Brysson Cunningham

III. NORRIS AND WHEELER DAMS

ON the side of the North American continent opposite to the valley of the Columbia River lies another notable valley—the Tennessee Valley, mainly in the State of that name, but also including parts of Mississippi, Alabama, Georgia, North Carolina, Kentucky and Virginia, with a basin comprising 40,600 square miles. For the co-ordinated development of this great territory, considerably larger than the whole of Ireland, a special body, the Tennessee Valley Authority, has been created by U.S. Congress with the duty of improving navigation, controlling floods, generating hydro-electric power and arresting soil erosion. For this purpose a series of ten dams of varying heights, and at irregular intervals, has been designed and in part executed along the course of the River Tennessee and its tributary the River Clinch. Perhaps the most notable of these, until recently, was the Wilson Dam, 137 ft. high and 4,860 ft. long, impounding a reservoir with a capacity of half a million acre-feet and generating power to the extent of 261,400 horse-power. The Wilson Dam was completed in 1925; but since that date, two other and even more striking dams have come into existence, the Norris Dam and the Wheeler Dam, completed as recently as last year.

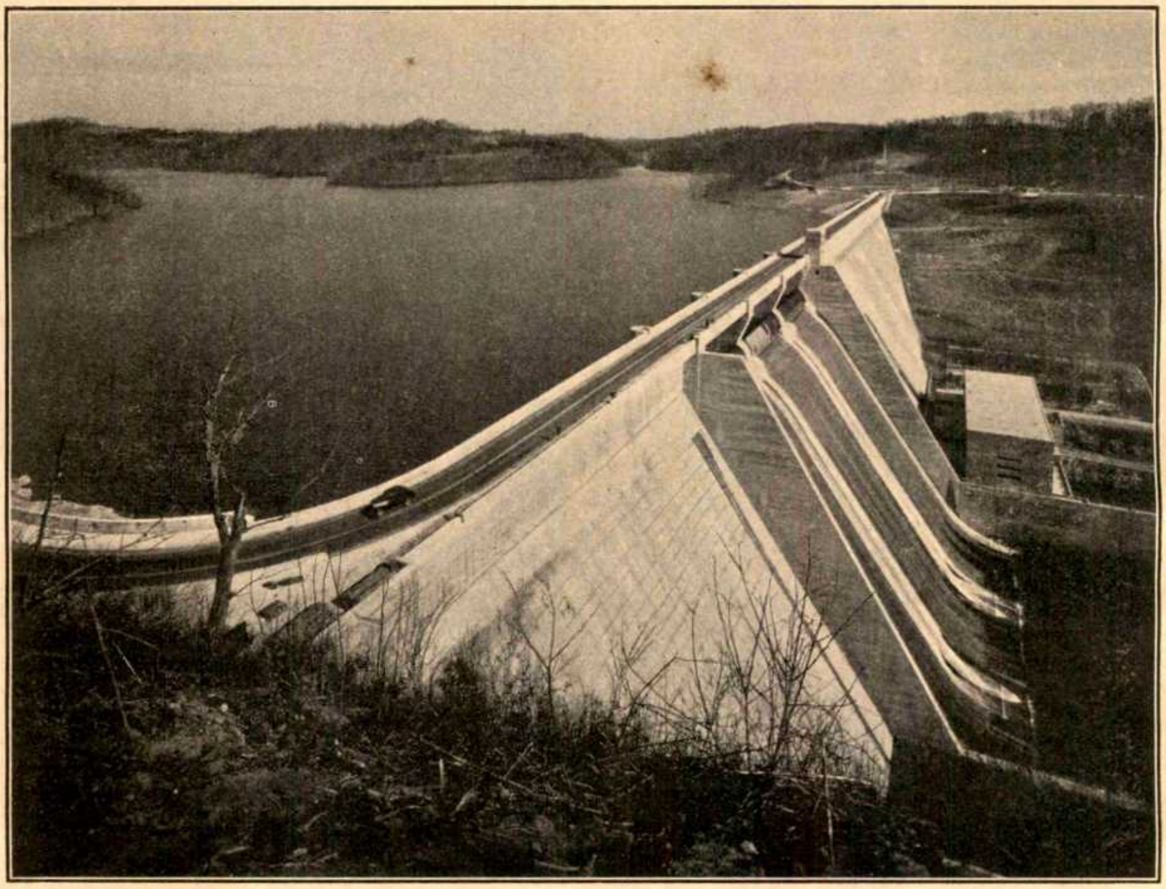

Fig. 1.

GENERAL VIEW OF THE NORRIS DAM ON THE CLINCH RIVER, TENNESSEE, SHOWING THE POWER HOUSE AND IMPOUNDED LAKE.

Of the two, the Norris Dam (Fig. 1) located on the Clinch River in north-eastern Tennessee, about 25 miles north-west of Knoxville, is the loftier and impounds a reservoir of greater capacity. The impounded area is more than 50 square miles, with a shore line of over 700 miles, winding in and out of many valleys formed by the hills above the dam. The reservoir capacity is 2,570,000 acre-feet at normal water-level, but may attain a maximum of 3,400,000 acre-feet. The dam itself is a straight mass-concrete structure, with a total length along its crest of 1,872 ft. It has a height of 265 ft above the lowest foundation level and is 204 ft. thick at the base. The spillway, confined within side walls of concrete, discharges into a concrete hydraulic 'jump pool', which extends 215 ft. downstream from the toe of the dam. Along the crest of the spillway, between two 12-feet concrete piers, are three hydraulically-operated steel drum gates, each 100 ft. long, designed to retain water at flood peak-level.

---

* Previous articles in NATURE, May 1, p. 738, and May 22, p. 823.

Though primarily a flood control and navigation work for the Tennessee and Mississippi Rivers, the Norris Dam is provided with power-generating plant consisting of two 66,000 horse-power generators. The cost of the entire installation was 35 million dollars (£7,000,000).

The Wheeler Dam (Fig. 2) is not remarkable for its height, which is only 72 ft., but it has a length of 6,335 ft.—1,475 ft. more than the Wilson Dam and 4,463 ft. more than the Norris Dam. It is located on the Tennessee River, 275 miles above Paducah, Kentucky, where the Tennessee joins the Ohio. Situated at the upper end of Wilson Lake, it is 15½ miles above the Wilson Dam at Muscle Shoals. It impounds a volume of water aggregating 1,260,000 acre-feet in a reservoir which has a shore line of 951 miles.

The dam is a gravity concrete structure, with the above mentioned length of 6,335 ft. composed, successively, of a non-overflow section 177 ft. long, 613 ft. power house, another non-overflow section 718 ft. long, 2,700 ft. of spillway, 1,756 ft. of non-overflow, 162 ft. of navigation lock structure and a final non-overflow section of 209 ft. to the north bank of the river. The spillway is divided into sixty bays, each bay being surmounted by a radial gate, 15 ft. high and 40 ft. long.

The power plant is of the outdoor type, with no housing over the crane or the generating units, the generators being protected from the weather by metal covers. The station is designed to accommodate eight main generating units of an

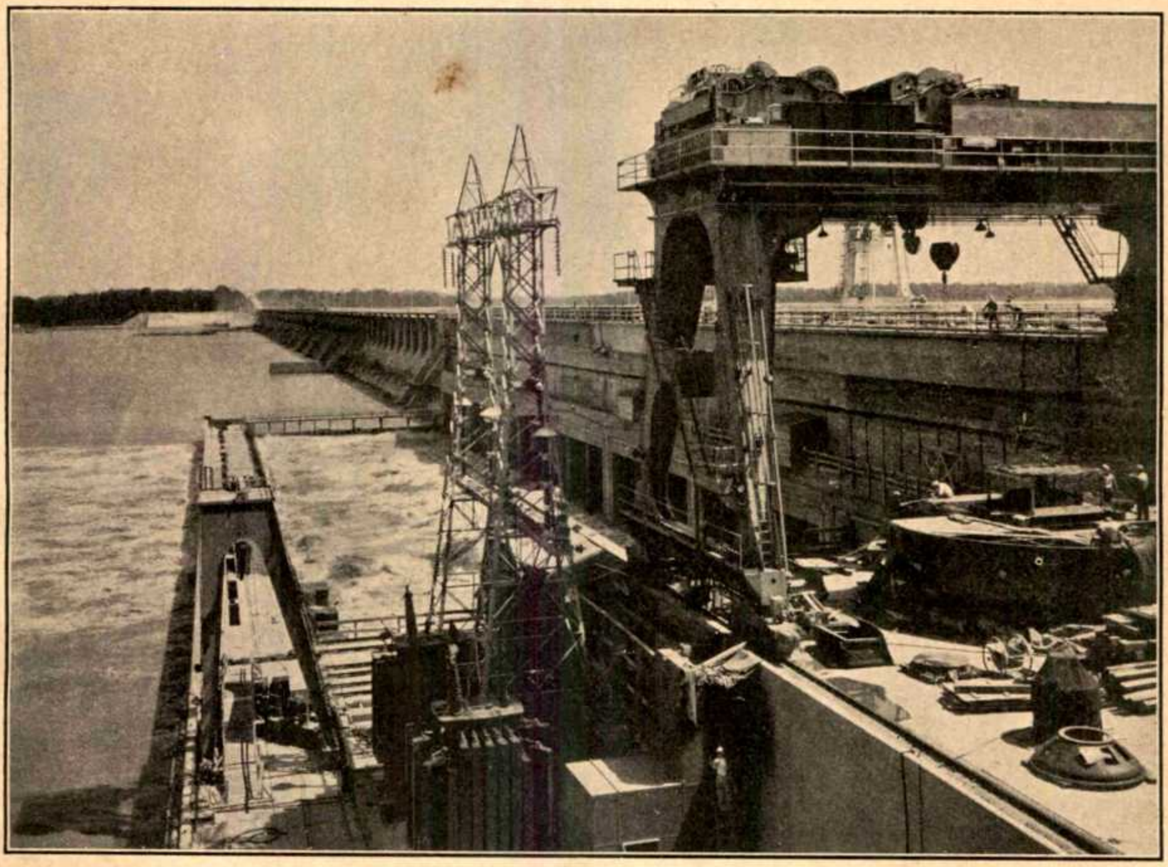

Fig. 2.

DOWNSTREAM VIEW OF THE WHEELER DAM ON THE TENNESSEE RIVER IN ALABAMA.

aggregate capacity of 360,000 horse-power. Only two units of 45,000 horse-power each, have as yet been installed. The system came into operation on November 9 last.

The individual projects, which have been described above, form part of an organized design for the utilization of the resources of the whole of the Tennessee watershed, by means of storage reservoirs in the headwaters, which will retain the run-off during the rainy season and release it during the dry season, so regulating the flow during the whole year to suit the requirements of navigation and to remove the danger of flooding.

Another interesting and important feature of the undertaking is the arrest of soil denudation. Under the influence of heavy rainfall, millions of tons of fertile top soil are removed from the hillsides, and further large quantities are lost by sheet erosion on the plains. This silt would normally be transported by the river currents over long distances, but the interposition of a series of dams causes it to settle and enables it to be reclaimed. But, going a step further back in preventive measures, the Authority is engaged in treating the eroded hillsides and encouraging the growth of vegetation with the aid of plant foods, and in particular, phosphates. At Muscle Shoals, a demonstration unit has been built to produce triple superphosphate from the raw phosphate rock found in central Tennessee. The electric power used for this purpose is derived from the hydraulic energy converted at the impounding dams.

The information on which the foregoing article has been based has been courteously supplied by the Tennessee Valley Authority, to which also I am indebted for the photographic illustrations.

Natural and Artificial Membranes

THE late Sir William Hardy was responsible for the foundation of the Colloid Committee of the Faraday Society, the duties of which were periodically to call meetings at which biologists, physicists and chemists could meet to discuss topics of mutual interest. The fifth meeting of this character was held on April 22–24 at University College, London, under the presidency of Prof. M. W. Travers of Bristol and the chairmanship of Prof. R. A. Peters of Oxford, the subject of discussion being membranes, their properties and functions. This particular meeting was graced by the presence of a number of distinguished foreigners, amongst whom we may include Dr. Ancel Keys of Rochester, Min., L. R. Blinks of Stanford, Mrs. Brooks of Berkeley, Cal., Prof. E. Gorter of Leyden, Prof. R. Collander of Helsingfors, Prof. E. Manegold of Dresden, Prof. Kurt H. Meyer of Genthod-Genève, Dr. W. Teorell of Uppsala and Dr. W. Wilbrandt of Bern, who all took part in the discussion. We were also pleased to note the presence of Profs. H. Mark and W. Ostwald, constant visitors to these meetings. It was to be regretted that several distinguished scientific workers were unable to present their papers; these included Profs. A. Krogh, Newton Harvey, E. Ponder, W. J. V. Osterhout and Cole.

It was clear from the contributions and from the discussion that in spite of the importance, both structural and functional, of membranes in organized living systems, we are still a long way from obtaining a complete description of the microstructure of even one of these or a general interpretation of their behaviour. It would appear that all natural membranes are composite in the sense that they contain both a lipoid-like and a non-lipoid component. The structural relationship of the components to each other is still *sub judice*. Exponents were not lacking of the extreme view of complete stratification of each component, one possibly in a monolayer, as well as those who upheld the view of a systematic mosaic or even haphazard intermingling. Some species of interaction, at least between the components of each 'phase', appears necessary to account for the physical properties of the complete membranes.

Whilst cationic and anionic permeability of the protein component of the membrane and the 'solubility of organic substances' in the lipoid component, as well as the ionic partition as defined by the Gibbs – Donnan membrane equilibrium are readily understandable in general terms, it appeared to many that these now well-recognized and important factors do not suffice to account for all the observed phenomena. So many questions were asked by our biologist friends at the meeting for the consideration of the physicist and chemist that it seemed difficult at times to realize how much progress had been made since the first meeting summoned by the Colloid Committee. There were three questions raised of unusual interest to many non-specialists present, to which no generally satisfactory answers could be given. These were the apparently abnormal behaviour of the potassium ion, the origin of bio-electric phenomena and the mechanism of narcosis.

In a medium containing a variety of salts, no satisfactory mechanism has been proposed for the relative enrichment in potassium of a portion separated from the bulk by means of a membrane, for example, red cells as discussed by Dr. M. Maizels. It was doubtful whether membrane charge, ionic size, solubility or complex formation could be the operative factors. It may be significant that not only is the lipoid/water partition coefficient for many potassium salts or complexes favourable for such separation, a view supported by Prof. Osterhout, but also that the ionic mobility of the potassium ion is some fifty per cent greater than that of the sodium ion, and thus in a dynamic system with migrating water as medium some separation should be possible.

According to Profs. S. C. Brooks and W. Stiles, separations due to mobility difference might be effected by exchange with ions, for example, those of carbonic acid produced in the metabolism. But if the final dynamic distribution of ions be calculated on the basis of a steady Donnan diffusion equilibrium, Dr. Teorell showed that under biological conditions the accumulation due to interdiffusion could not amount to more than 2 per cent.

If separation be accomplished by continued ionic transport involving an electric potential or a counter current of flowing liquid, it serves to emphasize the fact frequently forgotten by the non-biologist that these interesting properties are exhibited by living systems, and as such their dynamic state, involving possibly a continuous and steady flux of ions or liquid, may prove of paramount importance.

Such a theory demands the existence and the maintenance of an osmotic or an electrical gradient present within the membranes. From the discussion supported by Dr. G. S. Hartley, it was considered that diffusion or non-polarizable potentials could perform work; Prof. H. Freundlich suggested that work could also be obtained from temperature gradients (Soret effect). Drs. D. Gatty and R. B. Dean pointed out that redox potentials cannot be responsible for ionic accumulation. Dr. F. C. Steward and Dr. Ancel Keys inclined to the view that water and salt transport through plant cells and gills were due to metabolic processes oxidative in character.

Similar considerations may apply to the phenomena of bioelectric potentials. Some confusion exists owing to the misapprehension of the facts concerning the Donnan potential; namely, that the membrane potential can only be measured either electrostatically by the use of non-reversible electrodes in the two solutions separated by the membrane, or by the difference in the potentials given by each solution separately to a reversible electrode against a standard electrode in a solution containing the common ion. In spite of the fact demonstrated beautifully by Prof. Kurt Meyer that both acidophil and basophil membranes can be detected by staining methods in systems exhibiting bioelectric phenomena, it is not only doubtful whether these methods are certain criteria for selective ionic permeability, but also the serious difficulty that currents can be drawn from these presumably readily polarized systems does not appear to be surmountable unless a dynamic mechanism is operative.

A number of papers, including those of Profs. K. C. Cole, L. R. Blinks and Drs. Dean and Gatty, involved the use of electrical measurements to obtain information as to the equivalent electrical circuit which a cell with various hypothetical structures would present; *inter alia* it was brought out that Frickes' previous estimate for the thickness of the red cell wall must be considered in error.

An excellent summary of the views as to the origin of potential differences obtained in nerves was given by Dr. S. L. Cowan, who showed that diffusion potentials alone are not adequate. Dr. H. Rosenberg elaborated the core conductor system, whilst Mr. J. Z. Young discussed the chemical evidence as to the structure of the axon and the myelin sheaths of the nerve. He suggested in a general way that radially orientated lipoid layers may be responsible for nervous stimulation. It may be significant in this connexion that the phase boundary potentials exhibited by monolayers at interfaces are generally much larger than those potential differences obtainable by a Gibbs–Donnan distribution in biological systems containing a relatively high salt concentration; such monolayers on polarization naturally accumulate ions, and provided there exists some mechanism for destroying or changing the monolayer on stimulation, the result would be an ionic flow. Papers were communicated on the properties of protein monolayers by Prof. E. Gorter, by Dr J. S. Mitchell and Dr. J. H. Schulman. The Overton lipoid solubility hypothesis of narcotic action was revived in new form by Prof. Kurt Meyer, utilizing oleic acid as the model for the lipoid in evaluating the critical partition coefficients.

Prof. A. J. Clark, in a critical review, pointed out that the problem did not appear as simple as suggested by either Overton or by Traube, and that it appeared probable that selectively narcotizable and differentiated areas were involved. Several anæsthetics do not appear to conform to the oleic acid solubility rule, and the response of various types of nerve systems is not identical. The hypothesis advanced by Dr. Schulman and the present writer, in which interaction of the polar head or the non-polar portion of a narcotic with a lipo protein complex, appears to overcome the disadvantage of the older theories, but in its present state of development is too general and vague to be of much practical utility.

Papers dealing with the more practical side of artificial membranes were presented by Prof. Manegold and Dr. W. J. Elford. Dr. G. S. Adair gave a paper dealing with refinements of the Donnan membrane equilibrium.

The meeting was one full of interesting topics, but somewhat discursive owing to the attempt to deal with too many diverse phenomena at one time.

ERIC K. RIDEAL.

The Soviet Expedition to the North Pole

THE institution of a station for scientific research within a few miles of the North Pole marks a new phase in polar exploration, and is a development of the intensive exploration which the Soviet Union has pursued in Arctic regions during the last few years. The earliest attempts to penetrate high northern latitudes, away back in the sixteenth and early seventeenth centuries, were inspired by the hope of direct trade routes with the Far East and were alternatives to the still older attempts to find the North-West and North-East Passages. The early nineteenth century saw a revival of the northern ventures, and the Franklin disaster in the middle of that century led to a focusing of interest in polar regions, and stimulated journeys that were more adventurous than scientific in their outlook. But in an age of exploration that relied on man-hauled sledges and preserved food, that feared low temperatures and had to reckon with inevitable scurvy, the inner polar regions maintained their isolation.

Petermann's hypothesis of an open polar sea led to more than one failure and was utterly refuted by Nares, Greely and others. Then Nansen, imbued with scientific aims, brought a new technique to bear on the problem. The pack-ice that had thwarted his predecessors was to afford him the means of advance, and so in the drifting *Fram* he penetrated to lat. 86° N., and on foot some miles farther north. Nansen discovered a deep, landless polar ocean covered with drifting pack-ice. There the solution of the polar problem was to rest for some years. Even if Cagni beat Nansen's record by a few miles and Peary actually reached the Pole in 1909, these expeditions were mainly adventurous achievements and added little to scientific research. Amundsen's attempt to emulate Nansen had its value but failed to gain a high latitude.

Sledge and ship had both played their part in different ages: air-voyaging was next to be tried. Early attempts were naturally failures. In 1925 Amundsen reached 87° 43′ N. by air and returned with difficulty. In 1926, with Nobile, he crossed the Pole by airship, and in the same year Byrd also reached the Pole. These attempts showed not only the possibility of flying in arctic regions but also revealed large smooth floes with a relative lack of pressure ridges in the vicinity of the Pole. None of these expeditions, however, stayed more than a few hours, and others much less, at the Pole or anywhere in inner polar regions. Thus observations were casual and of little help, while little or no oceanographical work could be done.

Prof. O. J. Schmidt, who is in charge of the Soviet expedition to the Pole, aims at a more valuable type of exploration in placing a party in the vicinity of the North Pole for at least twelve months. The experience of arctic flying and arctic conditions generally that Soviet aviators and explorers have gained in recent years makes this possible. In connexion with the northern sea route between Europe and the Siberian rivers, of which much use is now being made, meteorological observations from the far north will be invaluable, especially in relation to the movements of the pack-ice. These observations are to be taken both at sea-level and at high altitudes. The direction of the ice drift will be studied and Prof. Schmidt points out that the station will be shifting continually in position, but it is not known if this shift will be steadily in one direction or rotatory around a certain point. In any event, these movements will facilitate soundings of the depths of the Arctic Ocean, of which little is known.

Chemical and physical analyses of the water are important in relation to the inflow of Atlantic water, and the bearing of that inflow on ice formation and ice-wastage. Good and bad ice years have long been recognized at Spitsbergen, Greenland and in the Kara Sea, but the factors involved are not understood and prediction is impossible. Magnetic and geophysical researches are also planned and biological examinations of the sea-water will be made. The station will be in radio communication with Moscow, and, it is hoped, in flying communication through many months of the year. The smooth floes afford a suitable aerodrome, and shelters are being constructed. The Soviet Union Year Book Press Service, to which we are indebted for information, lays stress on the importance of the researches in establishing regular communication by air between Europe and America across the Arctic Ocean, a modern revival in new guise of the earliest dream of a transpolar route.

Prof. Schmidt has chosen as the resident leader of the station I. D. Papanin, who has had long experience in Franz Josef Land and at Cape Chelyuskin. With him are three other experienced men, E. T. Krenkel, P. P. Shirshov and E. K. Federov. The winter dwelling is to be a tent of duralumin and rubber lined with eiderdown, reindeer hide and canvas. It is 3 7 m. long, 2 7 m. wide and 2 m. high, and has windows of unbreakable glass. The whole tent weighs only 350 lb. This will replace the silk hut used on the expedition's arrival on May 21. Paraffin is to be used for cooking and for generating electric light. The original site of the station was 20 kilometres from the North Pole on the Franz Josef Land side

Obituary Notices

Prof. Alfred Adler

ALFRED ADLER, who died suddenly on May 28, was the son of a Viennese merchant. He was born in 1870 and educated in Vienna. He decided to study medicine and qualified at the age of twenty-five years. Soon after qualification he fell under the influence of Freud, and formed one of that close little group which developed the new science of psychoanalysis. He stood some of the almost universal abuse which was flung against the Psychoanalytical Society when the new ideas became known.

In spite of this, Adler's ideas never accorded closely with those of Freud and almost from the beginning he showed that he intended to take a different road from his master. Whereas Freud developed elaborate psychic entities based upon the unconscious—the id, the superego and so on—Adler tended to simplify instead of elaborate.

So early as 1907 Adler described the influence of what he called 'organ inferiority'. He described cases which showed that the inferiority of an organ or group of organs might occur as a tendency in one individual or even in a family. He noticed that one person might have a series of diseases all attacking, for example, the urinary system. In the case of a family, one member after another would suffer from diseases all centred on one organ.

From this idea of the inferiority of an organ or group of organs, Adler developed the theory of 'overcompensation'. He felt that not only did the body try to compensate itself for the weakness but even succeeded in fortifying itself to an unnecessary degree, as, for example, when the scar following a wound is thicker and stronger than the original skin. He believed that this 'overcompensation' was not limited to the somatic or body-structure but also invaded the psychic superstructure. The result of this was that the organ which started as inferior was finally so overcompensated that it became superior to the other organs. He gave Beethoven as an example of this process, his early deafness only increasing the capacity to compose more and more magnificent music.

Adler found that he could explain every phenomena by his principles of inferiority and over-compensation. He put forward his views openly, and as they did not accord with those of infantile sexuality which Freud was developing at this time, there was a feeling of tension in the Vienna group of the newly formed Psychoanalytical Society. Adler was therefore asked to read a paper in which he could put his ideas before the Society. The result was a tremendous storm and, in spite of the fact that he was president of the Vienna Group, he was asked to withdraw. He did so and took nine other members with him. He then founded the Society for Individual Psychology (first called the Society for Free Analysis).

Away from the trammels of the Freudians, Adler developed better and applied his views to all types of neurosis. He thought that all neurotic illness was caused by a feeling of inferiority and a wish to dominate the environment through illness. This feeling of inferiority was engendered in childhood by the infant's weakness and its relation to its parents and brothers and sisters. This view is, of course, in direct contradiction to that of Freud, who believes that neurosis is the result of maldevelopment of the sexual instinct, which produces fixations at various psychic levels.

Adler felt that since man has the greatest strength, women must have a desire to be masculine and that neurotic illness in them is to be attributed to their wish to possess the strength of a man. He called this the 'masculine protest'. He believed that this was the cause of prostitution, homosexuality and even crime, as well as neurosis. Much of the neurotic illness in men, he thought, was due to the feeling of inadequate masculinity. All symptoms were explicable as symbolic attempts to express a purpose—in fact all neurosis was the expression of a purpose; fear of falling, for example, was explained as a fear of 'falling' sexually. Vomiting was a desire to reject some unpleasant thought or fact, and so on. He called this symbolization 'organ jargon'.

Adler's psychology is explanatory and easy to understand, but it lacks a coherent systematization such as one finds in the psychoanalytical theories. This looseness allows anyone to interpret the theories as he fancies, and tends to reduce them to art rather than science. Adler himself felt this, and a year ago told the writer that he thought that many who preached his views did not properly understand them. He was reluctant to build a rigid system, however, since he felt that the human mind was not easily crushed into any inflexible mould.

Adler worked in Vienna until a few years ago, when he left and accepted a professorship in America. He has visited England nearly every year since in order to lecture. He was a lecturer of singular patience, and would answer questions long after his lectures were supposed to have finished. He was a man of great friendliness—those who knew him might differ from him in theory but they could not quarrel with him in person for he never showed the aggression of which he wrote so much.

Major J. H. Hardcastle

MAJOR JOHN HERSCHEL HARDCASTLE, who died at Sidcup, Kent, on April 21, was born on May 9, 1870, at Netherhall, Bury St. Edmunds, a son of the late Henry Hardcastle, barrister. His maternal grandfather was Sir John Herschel, the astronomer, and his great-grandfather was the famous discoverer of the planet Uranus.

Hardcastle was educated at Haileybury and the Royal Military Academy, Woolwich, passing out ninth from the latter; thence he received his commission in the Royal Regiment of Artillery in 1889. He was promoted to captain in 1899. In 1902 he joined the advanced class for artillery officers at the Ordnance College, Woolwich, and there came under the influence of Sir George Greenhill. After obtaining the 'p.a.c.' certificate he was employed by the Ordnance Board at Woolwich in 1904–6 on important research work on the resistance of the air to artillery projectiles. This work culminated in the production of the official Ballistic Tables, in the compilation of which he assisted. These tables are still used.

Retired from the Army in 1906, Hardcastle thereafter devoted himself to research work in internal ballistics and small arms, working successively with the firms of Kynoch and Nobel's Explosives. During this period he introduced the pointed bullet. At the beginning of the Great War he returned to Woolwich, and was given charge of the small arms range in the Arsenal. Here he continued his researches into the ballistics of small arms, and towards the end of the War, produced formulæ which facilitated the rapid calculation of small arms ballistics. He remained at Woolwich until 1924 and assisted in the compilation of the "Text Book of Small Arms". After his retirement from the Service he acted as ballistic consultant to Imperial Chemical Industries, Ltd., and B.S.A. Guns, Ltd.

Most of Hardcastle's publications are in the form of papers and articles in the *Royal Artillery Journal*. He put his scientific knowledge of small arms to practical use, as he was a very fine rifle shot and was in the English Elcho team. F. R. W. HUNT.

Prof. W. Natanson

POLISH science has sustained a heavy loss by the death, on February 26, of Prof. Władysław Natanson, who had occupied the chair of physics at the Jagellonian University of Cracow since 1904, after having been assistant professor there since 1894.

Natanson was born in Warsaw on June 18, 1864, his uncle, Jacob Natanson, being a Polish chemist of some distinction. He graduated as doctor of philosophy at Dorpat in 1888, having previously studied at St. Petersburg, Graz and Cambridge. He then went to Cracow, where his post-graduate researches in physics gained him the doctorate of that university too (1891). Three years later he became *Docent* and continued his work at Cracow until his death.

Practically all his life, Natanson was working in adverse circumstances. It was never easy for him to secure adequate equipment for his laboratory from the Austrian authorities in pre-War days, nor had the Polish Government funds to spare for several years after the country had regained its independence. In spite of this, Natanson succeeded in making valuable contributions to his science, particularly by his publications on the kinetic theory of gases, which he developed to explain phenomena connected with diffusion, expansion by heat, vortex rings, molecular collisions, etc.

Theoretical and mathematical papers from his pen and dealing with isothermal formulæ, Clerk Maxwell's law, the kinetic theory and dissociation phenomena have appeared from time to time in British periodicals, but most of his work was published in Continental journals. In 1903 he observed the accidental double refraction of liquids, which he endeavoured to explain by a molecular theory of refraction, reflection and extinction. He is perhaps best known in Great Britain for his investigations on the dissociation of nitrogen peroxide on heating, and its re-association on cooling.

For his own countrymen, Natanson contributed articles on scientific phenomena (several, for example, dealt with the blue colour of the sky) to the semi-popular reviews and he also wrote some standard text-books of physics. His "Elements of Physics", first published at Lwów in 1894, has gone through five editions. Prof. Natanson also had a wide knowledge of the history of science, and his biographical sketches of Bacon, Newton, Lord Kelvin and others did much to stimulate an interest in British culture and science among the Polish people. He was one of the original members of the Cracow Academy of Sciences, and was for seven years the editor of its publications. Later his work gained him recognition abroad, and among other distinctions he held the office of vice-president of the International Union of Physics. G. D.

WE regret to announce the following deaths:

M. Louis Ravaz, *correspondant* for the Section of Rural Economy of the Paris Academy of Sciences.

Prof. J. M. Reade, professor of botany in the University of Georgia, on May 8, aged sixty-one years.

News and Views

Science and Peace Problems

DURING the National Peace Congress held in London on May 28–31, under the presidency of Dr. E. W. Barnes, Bishop of Birmingham, one of its commissions considered the attitude which members of the scientific and medical professions should adopt towards peace questions. The chairman, Prof. S. Chapman, who also gave the opening address in place of Prof. P. M. S. Blackett, who was absent through illness, advocated the establishment under international auspices of a world service of information on current events, as objective as possible, without comment or propaganda: controlled by a body of men chosen internationally according to some carefully devised scheme (like the judges of the Hague Court), for their personal qualities of judgment and impartiality; the daily bulletin being broadcast in the principal national languages, to provide men and women everywhere with a basis on which to form their political judgments. Dr. H. Joules and Dr. Howard Hughes described the organization and work of the Medical Peace Campaign.

THE meeting devoted much time to the discussion of the present rearmament programme; criticism was made of its exclusive emphasis on imperial defence rather than on collective security, and its execution by private firms for profit, without the safeguards recommended by the Royal Commission on Armament Manufacture. The official plans for air raid precautions were also discussed, and the experiments in progress by peace groups of scientific workers at Cambridge and Oxford, which question the efficacy of those precautions (see NATURE of April 10, p. 606). Members of these groups outlined the means which had been found effective in arousing interest among laboratory workers and maintaining discussion of peace. While it was judged unlikely that scientific workers would be able to reach common ground on the question whether or no they should participate in military preparation, tolerance between men taking different attitudes on this question was urged, and co-operation in peace work to the utmost possible extent. It should be made clear that men of science, in common with most members of the public, regard war as degrading to human progress as well as futile, and are willing to help in national and international work aimed at discovering and removing its causes and preventing its recurrence.

Relations between Science and Philosophy

THE fourteenth 'Unity School' organized by Mr. F. S. Marvin was held in the last week-end in May at Farnham Castle, and was a great success. The subject for discussion was the "Relations between Science and Philosophy", and as both sides were well represented and a large proportion of the disputants were fairly young people, the debates were as lively and vigorous as they were invariably friendly. Though it was remarked afterwards that there seemed little 'unity' in the arguments, it may well be that a perfectly frank statement of difference in an atmosphere of friendly feeling is the best way to reach a useful working agreement. There was certainly no attempt to set up any water-tight compartment for philosophic thinking on one side, or any rejection of the useful function of philosophy by the men of science on the other. The only body of people who seemed to stand isolated and not acceptable to either side were the 'logical positivists'. But Wittgenstein was only a name—if so much—to most of the audience, and further investigation was clearly necessary.

ON the side of science, the most novel and striking contribution was made by Dr. Redcliffe Salaman, director of the Potato Virus Research Station at Cambridge. His demonstration of the infinitesimal size of these organisms introduced one into a region where vital and inanimate objects seem to exist indistinguishably side by side. He gave full details of the discoveries which have lately been made in this sphere in the United States, especially by Stanley. A full and useful discussion followed as to the nature and working of the protein crystalloid bodies now revealed in certain viruses. It turned largely on matter which has been communicated to NATURE, and left many of the audience wondering whether in these crystals something has not been found which is an actual link between living and non-living. It was decided at the close of the proceedings to continue the series of 'Unity Schools' on somewhat similar lines next year. Mrs. Innes, of Coneydale, Welwyn Garden City, will be glad to answer any inquiries. Contact between the various branches, especially of physical and social science, was felt to be the most useful line of approach to 'unity' at the present time.

Total Solar Eclipse of June 8

FROM Press reports, it appears that the total eclipse of the sun was observed under perfect conditions on June 8 at Canton Island in the South Pacific, where the American expedition organized by the U.S. Naval Observatory and the National Geographic Society of Washington had established its stations (see NATURE, April 24, p. 698). The *Daily Telegraph*, in co-operation with the National Broadcasting Company of America, arranged for Prof. A. Fowler to speak from a studio in Broadcasting House, London, to leading astronomers observing the eclipse on Canton Island, and the conversation is described in the issue of June 9. It appears that many photographs were taken, and that the corona, as was expected, was of the type of maximum solar activity.

The spectroscopic programme also seems to have been carried out successfully. The *Daily Telegraph* is to be congratulated upon its enterprise in obtaining direct information by radio of observations of an eclipse from a station more than 9,000 miles away. This very remarkable achievement merits a place in astronomical history.

Blood Groups in Africa

AT the beginning of April, Dr. Ronald Elsdon-Dew and Mr. J. de Bruijne, of the South African Institute of Medical Research, left Johannesburg on a prolonged tour of investigation of the blood groups of African peoples, and more especially of the Bantu. They propose to examine various tribes in Southern and Northern Rhodesia, Nyasaland, Tanganyika, Kenya, the Anglo-Egyptian Sudan, Uganda and the Belgian Congo. Dr. Elsdon-Dew, who holds the appointment of assistant pathologist in the Medico-legal Department of the South African Institute of Medical Research, has been engaged on an intensive study of the African blood-groups since 1932, and has examined the blood grouping of more than five thousand South African Bantu. In publishing his results, and the somewhat startling inferences as to the racial history of Africa to which in his opinion they appeared to point, he emphasized the fact that theorizing on the serology of African peoples must of necessity be tentative, for in this respect Africa is still the Dark Continent. The present expedition has been undertaken to remedy the lack of material for purposes of comparison which gave to his ethnological argument a highly speculative character, more especially as regards the existence of a hypothetical primitive black race, possessing neither the *A* nor the *B* groups, to which his results appeared to point, and with which, serologically, the Southern Bantu apparently showed a closer affinity than any other people of which the blood groups were known. The expedition, which is travelling by motor caravan, will be at work for about six months.

Local Archæological Studies in Nottingham

PUBLICATION of the first annual report of the Excavation Section of the Thoroton Society of Nottinghamshire falls opportunely at a moment when attention has been directed in Parliament to the opportunity open to local archæological and scientific societies to educate their neighbours, the local authority and the local public generally, as to the desirability of preserving for posterity buildings and erections of historical or æsthetic interest and places of natural beauty (see NATURE, Feb. 27, p. 345). The Excavation Section of the Thoroton Society has been formed as an outcome of the enthusiasm of a small number of students of the past history of the city of Nottingham, but more especially through the efforts of Mr. G. F. Campion, who was anxious that the work of local excavation carried out by himself and his father before him over a number of years should be placed on a permanent footing. Very wisely it was decided not to form a new society for this purpose, but to join forces with the Thoroton Society, the long-established centre of archæological and antiquarian interest in the county. Thus the activities of the newly established section will be directed not only to continuing the work of excavation, but also to the expert examination and record of the numerous evidences of the city's past cultural history which are being brought to light with increasing frequency in the building operations in progress in connexion with the improvement and enlargement of business and other premises in Nottingham. It should at least be able to ensure that nothing worthy of note is overlooked—a matter of much importance in an area like Nottingham which is honeycombed with underground caves. The record of the first year's operations covers not only the excavations in Nottingham's Norman and Plantagenet castle, and a Roman fortress, but also the supervision of excavations for building operations on eight sites, which produced some interesting samples of medieval pottery, including a fabric unknown from any other area and thought to be an exclusive product of Nottingham.

Miocene Implements

A NUMBER of years ago, the late Mr. Edward Westlake collected a very large series of specimens of flaked chert and flint from Upper Miocene deposits at Aurillac, and other sites, in the Cantal, France. These specimens, which number several thousands, are now housed at the Museum, Ipswich, where they are being studied by Mr. Reid Moir. When his examination of the collection is completed, Mr. Reid Moir proposes to describe it; but it may be said that a great many of the specimens exhibit, in a marked degree, certain characteristics which have been generally accepted as indicative of artificial shaping. Archæologists, and those interested in the antiquity of man, owe a debt of gratitude to Mr. Westlake's insight and care in getting together such a vast and important collection, which, from many aspects, is unique. There would seem to be no doubt as to the Upper Miocene age of the deposits from which the specimens were derived, and their adequate description may well prove to be a significant contribution to the solution of the problem of the antiquity of the human race.

Dry Crossings of the Nile

WITH reference to the two letters to the Editor in NATURE of June 5, p. 961, under the title "Dry Crossings of the Nile", from E. J. Wayland and Dr. H. E. Hurst, we have received the following from Dr. A. E. H. Tutton: "It may be of interest to add to the record of the observations by Dr. Wayland, from the air in 1930 and by an actual passage on foot in 1933, that a natural bridge does from time to time exist across the higher reaches of the Nile, strong enough to bear the elephant, a still more remarkable observation by my late brother-in-law, Mr. Leonard Loat, made and recorded by him in the year 1902, during his survey of the fishes of the Nile for Lord Cromer's Government and the British Museum (Natural History). In a letter to me describing the difficulties then being met with, owing to the remarkable density and solidity of the 'sudd' between Fashoda and Gondokoro, he states that he had just observed a herd of over two hundred elephants walking on the sudd over the river. When he returned to England for a short leave, before undertaking a similar survey up the Blue Nile, I asked him whether he had recorded a solid fact or was indulging in a traveller's tale, as it seemed a very extraordinary circumstance, if true. He was most emphatic, however, as to its being literally true, and that he had ceased to count the elephants after the two hundredth; also that he had been accompanied by a big-game hunter friend at the time, as well, of course, as by the Egyptian skipper and Sudanese crew of his little survey vessel, a specially fitted dahabeyah, all of whom were greatly interested in the unusual spectacle. It is referred to in the obituary notice of Mr. Loat's work which appeared in *The Times* of April 30, 1932."

Memorial Tablet to Telford

DURING the conversazione of the Institution of Civil Engineers held on June 2, the president, Sir Alexander Gibb, unveiled a small tablet in the newly completed extension of the main library recalling Telford's gift of books to the Institution. When Telford accepted the presidency in 1820, he wrote: "As proof of my sincere desire to promote the prosperity of the Institution, I beg leave to present it a collection of Books connected with the profession of a Civil Engineer; they will form no inconsiderable portion of a suitable library, destined, I trust, at no distant period to become a valuable one. . . ." The library now contains 62,300 volumes, and Telford's books, with some others, have been placed in cases under the window in the west wall of the extension. Hollin's bust of Telford stands on the top of the cases, just above the tablet recalling his gift, while the oil paintings which the great engineer bequeathed to the Institution of the Pont Cysylltau Aqueduct and the Menai Bridge have been hung one on each side of the window.

Hooker's Aneroid Barometer

THE British Association has recently received from Miss Hooker, daughter of Sir Joseph Hooker, a gift of the aneroid barometer which used to hang by the fireplace in Charles Darwin's 'old study' at Down House, where it will now be replaced. A small repair has been kindly carried out by Messrs. Negretti and Zambra, and the aneroid is in working order. The face bears the words "Holosteric Barometer" and beneath them the figure 19, but no maker's name; the usual verbal indications of weather conditions are provided, and the dial is graduated continuously round the whole circle, figured from 25 in. up to 31 in., the remaining arc, between 31 and 25 in., being also graduated, as the whole scale is, in fiftieth parts of an inch. A small label, affixed perhaps when the instrument came into Hooker's possession, bears the name of "C. Darwin".

New Central Botanical Gardens for Moscow

BOTANICAL gardens, to be known as the Central Botanical Gardens of the U.S.S.R., will shortly be constructed on the southern and northern slopes of the Lenin Hills, on the outskirts of Moscow, according to the Soviet Union Year Book Press Service. The gardens will occupy a site of 825 acres, bounded by the projected Rublevskoye Chaussee, the Palace of Soviets, the Andreyev Canal and the Moscow River. A considerable part of the site will be used as a scientific research station. Special hothouses and structures will be put up in this section for the purpose. The middle of the Gardens will have a group of hothouses with varying artificial climates for the growing of plants from all over the world. A model orchard will be used for showing Michurin and other horticultural experiments. The Botanical Gardens will be attractively laid out with terraces, fountains and waterfalls. A funicular railway will connect the Moscow River Embankment with the top of the Lenin Hills. The Academy of Sciences of the U.S.S.R. has appointed a special commission to take charge of the designing and construction of the Gardens. The Commission includes V. L. Komarov, president of the Academy, Prof. N. I. Vavilov, Prof. B. A. Keller, A. M. Lezhav, director of the Central Department of Sub-Tropical Crops of the Commissariat of Agriculture of the U.S.S.R., and I. S. Gorshkov, director of the Michurin Central Laboratory of Genetics.

Future of the Coal Gas Industry

THE seventy-fourth annual meeting of the Institution of Gas Engineers was held on June 1–4, under the presidency of Mr. Stephen Lacey, of London. The papers contributed illustrated the problems and trends of the gas industry to-day—the tendency gathering in momentum on one hand to replace the consumption of raw coal by smokeless fuels and methods, and on the other to use fuels in a 'fluid' form amenable to ready and automatic control. The gas industry as a producer of smokeless fuels—both solid and fluid—is deeply involved in this trend, and the papers read retailed divergent opinions as to the future. A major problem of the industry is to maintain an economic balance between coke and gas. In Great Britain, gas engineers do not anticipate an early displacement of solid fuels; the industry must look for a combination of the two. Mr. C. F. Broadhead, of Melbourne, Australia, influenced by the acute instability of markets for by-products in that country, favoured concentration on complete gasification of coal. This idea, which is by no means new, is attracting renewed attention, and as Mr. Lacey said, is now the aim of an important branch of the Institution's research work. The uncertainty about the future of the supplies of suitable gas coal has stimulated interest in this problem. It has long been felt that the service of the gas industry would be more efficiently rendered if organized into larger units. Such an organization of the electrical industry has been imposed by law and a somewhat analogous process is now proceeding in the gas industry, but voluntarily, and by the formation of corporations or holding companies. This process has evoked a mixed reception, and a paper by Mr. G. M. Gill records how the holding companies have already given technical and financial assistance to many small isolated companies, enabling them to pursue a more progressive policy.

A Meteorological Chronology

GEOPHYSICAL MEMOIR No. 70 of the Meteorological Office, by C. E. Britton, is entitled "A Meteorological Chronology to A.D. 1450". It is a symposium of various compilations of historical references to the weather of the British Isles, and a full bibliography of these is given at the end of the memoir. The main body of the work is in diary form, each year for which any notable meteorological event has been recorded appearing in turn, with particulars of such events. The first year is 2668 B.C., but it is pointed out that these very early dates, derived from such sources as the Irish Chronicles, are "largely legendary", being probably in the nature of oral traditions. The events chronicled in these years are chiefly the overflowing of various Irish lakes and rivers. The traditional period is followed by the Roman period, and the author points out that the very large number of meteorological events assigned to those times by various annalists and chroniclers do not appear to have been recorded by any contemporary writer; many indeed appear for the first time on record in the eighteenth century, with no information from the chronicler as to where the information was obtained. A typical specimen of this class of record is that of Dr. Thomas Short of Sheffield, who published a "General Chronological History of the Air, Weather, Seasons, Meteors, Etc." in two volumes in 1749—a work that occupied the worthy doctor for fifteen years. Without disputing the interest attaching to a work of the character of this symposium, one may doubt if its scientific value for meteorology is appreciable. It is amusing to notice the sobering of the record in its later years—the gradual dying out of such events as several days' downpour of blood, for example—with its suggestion that a very large part of the events before, say, A.D. 1000, are pure inventions or unrecognizable distortions of happenings not so very different from those of modern times.

A Theory of Atomic Structure

OUR attention has been directed to a theory of atomic structure which has been elaborated by Mr. C. F. Krafft, of Washington, D.C., and published by him in book form under the title "The Mechanistic Autonomy of Nature, with 1935 and 1936 Supplements". In this theory the atomic nucleus has been discarded in favour of a system of vortex rings arranged in the form of polygons, which may break up into chemically active groups and then fuse with other similar groups to form larger polygons. Thus the valency 'bonds' are made up of protons as well as electrons and the structural centre of the atom is apparently void. Whether this theory will survive the critical examination of the physicist is not certain, but the author claims that it enables him to interpret the chemical structures of compounds like diborane B_2H_6, etc., which are apparently anomalous. He asserts that "the very existence of diborane flatly disproves the entire nuclear theory of atomic structure, and not even its endorsement by high authorities can save it". In view of this bold statement, it is interesting to recall the fact that this very problem was brilliantly solved quite recently by Dr. E. Wiberg, an account of whose work on the subject was published in NATURE of February 27, p. 381.

Storage Battery Cars

RECENT progress in the design of storage batteries has turned the attention of traction engineers to developing storage battery cars for use on rails. These cars are very trustworthy in service and simple to operate. The maintenance costs of the equipment are much lower than when Diesel engines are used. Battery maintenance is usually carried out by the manufacturers on the basis of the number of miles run, and the cost depends on the current price of lead. The 'standstill' charges affect about ten per cent of the total stock in service, and due to battery overhauls they are usually out of commission for three or four days during the year. According to *Electrical Industries* of May 19, charging the batteries is very simple. It is carried out at night by connecting them to a power supply, and when fully charged the current is automatically switched off. At the terminal points of the system the whole battery can be replaced in a quarter of an hour. The distance that can be covered in a single battery charge is now 185 miles. Trials on the German State Railways show that some cars can travel for 250 miles non-stop at 25 m.p.h., and half that distance can be covered at 40 m.p.h. In the first case the power consumption is 18 watt hours per ton mile and in the second 26 watt hours per ton mile. At the present time, there are 170 cars on the German State Railways and their average speed is between 37 and 47 m.p.h. The average yearly car mileage during 1935 was 38,500. In Poland, France and the north of Italy, storage battery cars, mostly of the double bogie type, are run on tramways and suburban lines. Each car carries about a hundred passengers and has four motors giving a total of about 180 horse-power.

The National Physical Laboratory

THE annual report of the Laboratory for 1936 is presented in a new form. Hitherto it has been a quarto volume of about 250 pages, well illustrated and cost 12*s.*; now it is royal octavo of 144 pages without illustrations but costs only 2*s.* 6*d.* The saving of space has been secured by the omission of detail of limited interest. The death of Sir Joseph Petavel, the director, was referred to in the last report and until the appointment of a successor Sir Frank Smith was in charge. Several members of the staff have been transferred to other Government Departments or have been absorbed by industry. Many of the senior members have taken part in conferences at home and abroad and have lectured in provincial centres of industry on the work of the

NATURE

SUPPLEMENT

No. 3528 SATURDAY, JUNE 12, 1937 Vol. 139

On the Origin of Laws of Nature

By Prof. E. A. Milne, M.B.E., F.R.S., University of Oxford

[IN NATURE of May 8, we published an article by Dr. Herbert Dingle entitled "Modern Aristotelianism". The article, as letters from a number of correspondents showed, created considerable interest, and it was decided to invite further contributions on the subject from a number of representative investigators. Prof. E. A. Milne, who was singled out by Dr. Dingle for particular criticism, has sent an article expounding the ideas behind his recent work and touching on many of the points under discussion. This serves as an opening article to a series of contributions, many of them sent in the form of "Letters to the Editor", which have been arranged roughly in the order of their content under the general title of "Physical Science and Philosophy". Finally, Dr. Dingle has summed up the discussion and dealt with some of the main points raised. It is hoped that a useful purpose will have been served by bringing together in this way a number of contributions bearing on the old question of the relation of physics to philosophy.—Editor, NATURE.]

As the status of a recent series of writings by me has been called in question, it may be permissible to give some statement of their general tenour. The following account contains nothing that is not already explicit or implicit in the original investigations, and will be superfluous to those who have followed the details.

The general object of the investigations[1] in question was to determine the consequences of the assumption that the universe is, on the average, homogeneous. Had I used this as an ordinary physical hypothesis, that is, used it in conjunction with the existing body of physical doctrine and laws of Nature, the investigations would probably have passed without challenge. But I did not so use it. By an extreme application of the principle of the economy of thought, I investigated the consequences of this assumption without appealing to any empirical quantitative 'laws of Nature' whatever. I used it as a sole basis of argument. I did so because it early appeared that very much more could be deduced from it than was commonly recognized.* At first, indeed, I used it in conjunction with well-known kinematic laws developed in the so-called 'special' theory of relativity. Hence the provisional name 'kinematic relativity'. But it soon appeared that these kinematic laws were themselves the first deductions from the basic assumption, or from allied but simpler considerations in kinematics. From October 1933, when I first gave in seminars in Oxford the substance of Chap. ii of "World-Structure", I have endeavoured to develop the consequences without any empirical appeal save to the existence of a temporal experience, an awareness of a before-and-after relation, for each individual observer. Such an appeal, as has been emphasized throughout, is necessary before *motion* can be described at all. This is well understood from the works of A. A. Robb, and it has been evident from the time of Zeno. The exclusion of all empirical appeals was not complete in my own writings, but it has been further completed in papers by G. J. Whitrow[2], A. G. Walker[3], H. P. Robertson[4], and others. Some similar work has been developed by L. Page[5], and further work on the meaning of uniform time is in preparation by me in collaboration with Whitrow.

The hypothesis is that the universe is homogeneous on the average in both distribution and motion, both of these being quantitatively measurable, in principle, by any observer by means of measures of angle and temporal experience alone. The single measuring instruments allowed are the clock and theodolite, and it can be shown to be possible for clock graduations to be chosen so that the motion appears to be uniform to all of a class of observers, this mode of clock-graduation constituting the definition of the measure of 'uniform kinematic time *t*'. The indefinable concept of the rigid transportable measuring-rod is avoided, and the vague 'pointer-readings' of current relativity are made explicit. Throughout, full attention has been paid to the theory of knowledge—to Einstein's principle of introducing only elements which can in principle be observed.

---

*It is fundamental because it enumerates a set of equivalent frames of reference.

It is an astonishing thing that the elimination of other empirical appeals, including all appeals to quantitative laws of physics, can be carried out as far as it can, however imperfect the present state of the theory. No one has been more astonished than the present writer. It is not an *a priori* belief to be scoffed at; it is a fact of experience to be reckoned with, that when we do thus eliminate such empirical appeals, regularities emerge (as logical consequences of the hypothesis) which play the part of the very laws of Nature which are *observed* to hold good. These regularities have the logical status of *theorems*, and the resulting logical structure has the status (or would have the status if it were perfect) of an abstract geometry based on axioms. It will be well therefore for a moment to consider what is meant by a geometry.

A geometry is a body of deductive inferences from axiomatic definitions which in effect afford the minimal descriptions of the subjects of discourse. The axioms of a geometry are essentially a complete set of definitions which delimit what we are talking about. The elements in the geometry—point, line, etc.—are never explicitly otherwise defined than as entities occurring in certain statements of relations. A geometer never says what a point *is*. Instead he makes a constructive statement about a point—he calls it an axiom—which affords a basis for inference. The logical consequences of the axioms constitute the theorems, and no 'fact' is appealed to in proving a theorem unless it has already occurred in an axiom or earlier theorem. This is what is meant by saying that geometry is an exact science—it makes no use of the principle of induction—it appeals to no empirical generalizations based on experience. The choice of axioms may be guided by suggestions derived from experience, but no recourse to experience is made in establishing the theorems. They depend for their validity on the self-consistency of the axioms and the freedom of the deductive steps from logical errors.

In this way systems are constructed which may or may not have their counterparts in the external world. We then appeal to observation to verify the existence, or establish the non-existence, of entities in Nature corresponding to the entities mentioned in the axioms—exactly or approximately as the case may be. For example, we can identify a given two-spread as a Euclidean plane by verifying (to a certain approximation) that the theorems of Euclidean geometry hold good in it; alternatively the two-spread may be such that the theorems of non-Euclidean geometry hold good in it. But in either case it is not that the theorems depend for their validity on recourse to observation or on any application of the principle of induction. It is their relevance to a particular state of affairs which can be so established. The role of observation is a double one: it is to discover theorems empirically, but it is also to verify the relevance of theorems discovered by inference from axioms, and hence to identify in Nature objects corresponding to, or approximately realizing, the entities mentioned in the axioms. The theorems exist in their own right. Thus when we say that geometry is an exact science, we are paying attention to one aspect—the deductive; we may equally say that it is an empirical science, namely, when we pay attention to another aspect—its relevance to Nature. In early Egyptian days, we understand, geometry was purely an empirical science; the Greeks carried it, though not quite perfectly, to its deductive phase.

Consider now physics. It has clearly an Egyptian aspect and a Greek aspect. The trend of physical investigation is at once to extend the number of known facts by empirical discovery, and to diminish the number of independent facts by establishing some as consequences of others. To the extent to which physics reposes on empirical laws of Nature not deduced from other laws—on 'brute facts'* capable of no further explanation—it is irrational and inexact; irrational because no reason can be assigned for the existence of these irreducible laws of Nature, and inexact because they can only be known to hold approximately, through the principle of induction. But we can contemplate the possibility of the completion of the second of the two trends mentioned, by reduction of the number of brute facts to the minimal description of what is the subject of discourse. Physics would then attain the status of a geometry. The minimal description, the relations satisfied by what *is*, would constitute the axioms. Theorems in the resulting logical structure would play the part of laws of Nature, and the validity of the theorems would depend, as in a geometry, on the self-consistency of the axioms and the correctness of the logical reasoning. The laws would exist not as regularities imposed from without but as a consequence of what *is*. The role of observation would again be to attempt to verify in Nature the existence of entities corresponding to those mentioned in the axioms or any afterwards constructed, by ascertaining whether the resulting theorems hold good in the external world. The relevance of the theorems to Nature would require to be established by observation, but these theorems or laws of Nature would hold good in their own right, as the inevitable consequences of our having said exactly what we were talking about.

Just as geometers have constructed systems and logical entities not realizable in Nature—like a four-dimensional cube—so here the resulting logical structure may not correspond to Nature. But just as results of great value have followed from the construction of non-realizable abstract geometries, so it is valuable to construct an abstract physics for its own sake. It is remarkable that those who are most prone to criticize my procedure on the ground that it is 'mere logic' immediately avail themselves of the results of 'mere logic' by adopting non-Euclidean geometries.

---

* It is not known whether this phrase is an insult to the facts or a compliment to the brutes.

In the deductive structure raised, the substratum or smoothed-out homogeneous universe plays the same part as the plane in Euclidean geometry. It is the platform on which, or the background against which, the entities constructed have the properties enunciated in the theorems. Instead of properties of patterns of points, we have properties of sets of fundamental particles. The difference from geometry is that the platform is a moving one (in some of its modes of description). We have superposed *motion* on geometry. Like the plane or any surface of constant curvature in geometry, the substratum is of the same nature everywhere. It is a remarkable fact that the theorems to which one is led cover the successive provinces of kinematics, dynamics, gravitation and (in preparation) electrodynamics, and agree in general outline with the empirically discovered laws of Nature concerning these provinces. Whether the structure in all its details is 'realized' in Nature is an interesting and important question, but it is more interesting that the procedure is possible and at least partially successful. Nature *is* very like the abstract structure. An example of identification by appeal to observation is the identification of kinematic time in terms of dynamical time by comparison of the laws of dynamics obtained deductively with the empirical Newtonian dynamics.

This throws a flood of light on the problem of the 'origin' of laws of Nature. Empirical physics by itself cannot attack this problem. A residue of laws of Nature, not otherwise explained, would partake of the character of magic. To believe in this would be a form of superstition. It would mean that there were two creations, one of the matter of the world, another of a set of laws for the world to obey., The alternative belief is that the universe is rational. By this I mean that given the mere statement of *what is*, the laws obeyed can be deduced by a process of inference. There would then be not two creations but one, and we should be left only with the supreme irrationality of creation itself, in Whitehead's phrase. We can only test this belief by an act of renunciation, by exploring the possibility of deducing from some assumed description of just *what is* the laws which *what is* obeys, avoiding so far as possible all appeal to empirically ascertained laws. Laws of Nature would then be no more arbitrary than geometrical theorems. God's creation would be subject to laws not at God's further disposal. The laws would be consequences of the world-shape.

As for the basic assumption itself, that the world is homogeneous, it is perfectly open for anyone to make a different assumption (for example, that it is not homogeneous, but stratified round a particular centre) and repeat the procedure. Either the laws of Nature would come out different—in which case we should have to attribute new effects to distant unobservable portions of the universe; or they would come out the same—in which case the original axioms would have been shown to be unduly restrictive, but the deductive character of the laws would be more secure still. Progress in this direction has been made by A. G. Walker, in repeating the procedure for a Riemannian space. But it was surely justifiable, in so unconventional a programme as the logical deduction of laws of Nature, first to explore the possibilities in the simple contexts of homogeneity and Euclidean private spaces. Through an unmapped region, one path must first be trodden.

The work was first criticized as being solely kinematical. Now that it has been developed so as to construct a dynamics and account of gravitation, critics appear to resent the fact that laws of dynamics come out as deductions. The individual investigator must be left in peace to state his own problems and solve them by his own methods, and criticism of these on the ground that they go beyond Renaissance science is merely a form of authoritarianism.

One further point may be mentioned. The procedure we have outlined is essentially different from that of general relativity. General relativity, on a basis of empirical experience, proposes certain laws of Nature, but is still, without further assumption, unable to say what are the contents of the world which is to obey them. In almost all its treatments of the cosmological problem, general relativity goes on to make the same assumption that I make, that the universe is on the average homogeneous. The assumption was first made by Einstein. But it now follows that general relativity makes redundant assumptions. For the assumption of homogeneity itself implies the laws that will be followed. It may be that the laws adopted in general relativity coincide with those that can be deduced from the assumption of homogeneity. If so, general relativity is fortunate. Actually investigations given elsewhere throw considerable doubt on the "field equations" of relativity, partly because the latter lead, if pushed to extremes, to inadmissible consequences. But the important point is that it is not legitimate *both* to assume a homogeneous universe *and* to assume laws for it to obey. Laws can be deduced from homogeneity, but the procedure is not reversible.

It may remove misapprehensions to remark that the actual discreteness or local inhomogeneity of the world in detail leads to no difficulties. Technical methods have now been developed for superposing on general homogeneity local variations, and for dealing with such systems as a spiral nebula.

Physical Science and Philosophy

Sir Arthur Eddington, F.R.S., Observatory, Cambridge

In his entertaining article in Nature of May 8, Dr. Dingle inveighs against a new departure in scientific method, which has grown out of the revolution of thought provoked by relativity theory. For my own part, I will not quarrel with the label 'Aristotelian'. Whether or not my view has anything in common with that of Aristotle, it presents a definite contrast to the 'Galilean' view; and I feel great satisfaction at having shocked a die-hard of the latter school.

But I think Dingle is wrong in identifying the Aristotelians with those whose deductions rest on a supposed uniformity of the universe. (I have toned down his rhetoric a little.) A conspicuous example is Dr. Hubble's deduction that the red-shift in nebular spectra is due to some cause other than velocity. But I would not class Hubble as an Aristotelian; he is more usually held up as a model of orthodoxy to errant theoretical cosmogonists. For my part, I have made a point of exposing a number of fallacies, current at one time, which arose from applying the uniform model to actual conditions without taking account of the irregularity of the universe. The distribution of the galaxies, like the distribution of the planets, comes under the heading "particular events and objects of our experience" which, according to my statement partially quoted by Dingle[1], cannot be deduced from epistemological considerations.

A doctrine is not to be judged by the follies that have been committed in its name. If Kepler concluded by Aristotelian sophistry that there can be only five planets besides the earth, Bode obtained by Galilean induction his law of planetary distances. The planet Neptune contradicts them both impartially. I can only accept responsibility for the "new Aristotelianism" in the form in which it has been promulgated and applied in my own writings. I here offer a short explanation and defence of this form.

In physical science *a priori* conclusions have long been anathema. It has come to be accepted as a scientific principle that we can have no *a priori* knowledge of the universe. Agreed; provided that by 'universe' is here meant an *objective* universe, as was clearly intended when the principle was framed. But I have calculated, for example, the mass-ratio of the proton and electron by an *a priori* method which does not involve any observational measurements. For present purposes we may assume that the calculation is sound, since criticism has not been directed against any particular step in the argument. What follows? We are given—

(*a*) It is impossible to have *a priori* knowledge of an objective universe.

(*b*) The mass-ratio has been found by an *a priori* method.

Therefore: *Knowledge of the mass-ratio is not knowledge of an objective universe.*

After a rather extensive series of researches, I have found that a great part of the current scheme of physics is deducible by *a priori* argument and therefore does not constitute knowledge of an objective universe. When the constant, which I had regarded as the last stronghold of objectivity, namely "the number of particles in the universe", surrendered, I could no longer resist the conclusion: The general laws of Nature (embodied in the fundamental equations of mathematical physics), including the universal constants associated with them, do not express knowledge of an objective universe. If anyone points out that in that case they are not *really* laws of Nature or natural constants, I do not object; but I continue to use the designation applied to them in current physics. Observation, besides revealing laws of Nature, supplies details of particular systems and events. It is in these particulars that the objective element in our knowledge resides; there is no objective element in the general laws.

One consequence of the new outlook, which, I believe, rouses the passions of the Galileans, is that a law of Nature has a compulsory character, and is not merely an empirical regularity which we have hitherto found to be fulfilled in our limited experience. Conflict with the laws of Nature is *impossible.* "Impossible" you may say "is a word which no genuine scientist should use". Very well; let us substitute another—which makes the laws no less compulsory. Conflict with the laws of Nature is *unobservable.* Physical knowledge, as ordinarily expressed, is not stated in terms of observables, and requires translation in order to get at its observational content. Carrying the translation into the language of observables further than it is usually carried in relativity theory and quantum theory, it appears that the supposed deviation would have no observational equivalent. It is like trying to find the English equivalent of a misspelt German word.

In the theory of relativity it was realized for the first time that induction from observation should be based on what the observer observes, not on what he alleges he observes. This elimination of metaphysical speculation and return to the "hard facts of observation", besides purifying and extending Galilean induction, was also the origin of the Aristotelian divagation. Attention was directed, not only to the result of the measurement (*a posteriori* information), but also to the nature of the process of measurement (*a priori* information). We cannot, of course, predict the result of the measurement from our *a priori* knowledge of how the measurement is going to be made; but it does not seem unlikely that we should be able to predict certain general properties that the resulting measurements will have. A valuer may arrive at the generalization *a posteriori* that no article in a certain house is worth more than sixpence; the same conclusion might have been reached *a priori* by noticing that the owner furnished it from Woolworth's. The observer is called upon to supply the furniture of the mansion of physical knowledge. The Aristotelian by watching his method of obtaining the furniture may anticipate some of the conclusions which the Galilean reaches by inspecting the furniture.

Consider an example. A measurement consists in comparing a relation between two entities with a relation of the same kind between two other entities, the latter relation being treated as 'standard'. It therefore concerns four entities in all. Without more investigation we are led to expect that this number four will in some way make itself evident in the world-picture which embodies the results of observational measurement. This expectation in itself tells us practically nothing*; many threads must be woven together before a pattern appears. But the example will serve to show where I get the straw for the bricks which I make—or drop—in my theory.

A more abundant source of *a priori* material is the fact that our inductions are based, not on observations generally, but on "good" observations, that is, observations made in (or reduced to) conventionally defined conditions. It must be emphasized that (according to Dr. Dingle) these conventions are entirely arbitrary. Faithful Galileans, who have no *a priori* theory of Nature, cannot speak of one convention being more 'natural' than another.

As a further example I may as well take what has probably been regarded as the most glaring application of Aristotelianism, namely, the result that the number of particles in the universe, N, is precisely $2.136.2^{256}$. I have not forgotten Kepler's fiasco with the number of the planets; but in attempting to out-Kepler Kepler, we have the advantage of three hundred years' progress. The number N is one of the constants of physics, ascertainable approximately by Galilean methods. I describe it as it is described in current physics; but, of course, if I show that it can also be calculated *a priori*, it cannot represent knowledge of an objective universe and therefore cannot be an arithmetical count of objective particles.

Quantum physicists tell us that a particle (say, an electron) is not normally in a definite place but is smeared over a probability distribution; also that electrons are not distinguishable from one another. That does not seem very promising material for counting. (I would suggest to quantum physicists who suffer from insomnia that, instead of counting sheep in a green field, they should try counting electrons in a probability distribution.) Nevertheless, quantum physicists tell us confidently how many electrons there are in a gram of hydrogen. Ten years ago I wrote with enthusiasm about Dirac's delightful dodge, which turns arithmetic into wave mechanics by means of a wave function whose eigenvalues are the integers—at the same time emphasizing that it was a dodge[2]. By this method the wave function, which describes a system physically, is made to supply an arithmetic for reckoning the number of its particles. When the quantum physicist states the number of particles in a system, whether few or many, he gives the number reckoned by quantum arithmetic. The natural constant N is a number in quantum arithmetic; it could have no other meaning, for Pythagorean arithmetic is a non-starter in the competition. When further we introduce the condition that the wave function of the universe is relativistic, that is, that it is the embodiment of information that has been obtained by observational measurements, we find that in the corresponding arithmetic the integers run only from 1 to $2.136.2^{256}$. This upper limit may be said to replace infinity in relativistic quantum arithmetic in the same sense in which the velocity of light replaces infinite velocity in relativistic kinematics. We can thus obtain the number of "all the particles that there are" from our *a priori* knowledge of the arithmetic that is used for enumerating them. From the philosophical point of view we have 'debunked' N; but here we must stress rather the fact that the Aristotelian method anticipates information, which when obtained *a posteriori* by Galilean induction is counted as a valuable addition to knowledge.

Finally, since the statement of my philosophy[1] quoted without its safeguards by Dingle has also been quoted by almost all the reviewers of my book, I would like to make it clear that it is not the basis but the unexpected conclusion of the investigation.

---

* In particular, it does not warrant numerological speculations. I think the number four introduced in this way is responsible for the four dimensions of space-time, *but only indirectly*. In the actual calculation the number of dimensions of space-time is reached by the route $\frac{4.3}{1.2}-1-1=4$.

Prof. P. A. M. Dirac, F.R.S., St. John's College, Cambridge

IN his article in NATURE of May 8, Dr. H. Dingle criticizes my letter to NATURE of February 20, on the grounds that it departs from the Galilean scientific method of building up theory to fit observations. The successful development of science requires a proper balance to be maintained between the method of building up from observations and the method of deducing by pure reasoning from speculative assumptions, and I think my letter satisfies this condition; but as it was written rather concisely, I would like here to restate the main points of the argument in a form which brings its observational basis to the forefront, and is essentially independent of cosmological theory.

We begin by taking all the constants of Nature provided by observation, comprising the atomic constants and some astronomical ones, namely, the gravitational constant, the red-shift of the spiral nebulæ per unit distance, and the average density of matter. (The last has a definite meaning on account of the fact that the spiral nebulæ are distributed with uniform density, as far as can be seen with the largest telescopes.) From these constants of Nature we construct all the simpler dimensionless numbers that we can, and make them all greater than unity by taking the reciprocals of those that are less. A remarkable result now comes to light. The numbers we obtain, instead of being scattered about in a random way, are distributed in clusters, there being one cluster of small numbers (the largest of these being the ratio of the mass of the proton to that of the electron), a second cluster of numbers in the neighbourhood of 10^{39}, and a third cluster of numbers in the neighbourhood of 10^{78}.

From kinematical considerations based on the assumption that the red-shift phenomenon appears the same when observed from different spiral nebulæ (a reasonable assumption in view of the uniformity in the distribution of the spiral nebulæ), one can deduce that the red-shift per unit distance is not constant in time, but is slowly decreasing, at the rate of about one part in 2×10^{9} per annum. Milne's work provides a detailed treatment of this question. One may adopt a picture using the recession explanation of the red-shift, when the red-shift per unit distance will be slowly decreasing because of the increasing distance of the nebulæ. (But one is not obliged to adopt this picture, there being another mathematically equivalent picture without recession, based on Milne's time variable γ.)

The red-shift per unit distance has the dimensions of $\delta\nu/\nu l$, that is, $(\text{distance})^{-1}$. To get a dimensionless number from it, we must multiply it by a constant of Nature with the dimensions of distance, the simplest of these being h/mc, e^2/mc^2, and the corresponding expressions with the proton mass replacing the electron mass. The numbers so obtained are all less than unity and their reciprocals are in the 10^{39} cluster. These reciprocals must be slowly increasing in time, on account of the decrease in the red-shift per unit distance.

I now make the hypothesis that the clustering of the dimensionless numbers is a fundamental natural phenomenon, which will hold for all time. This requires that, since some of the numbers in the 10^{39} cluster are increasing, they must all be increasing in the same ratio, and the numbers in the 10^{78} cluster must be increasing according to the square of this ratio. This is a tentative hypothesis, which one may hope will prove susceptible to experimental verification in its developments, though any direct test would be very difficult on account of the enormous time-scale involved.

S. Chandrasekhar, in his letter to Nature of May 1, makes an interesting contribution which, in the present terminology, would run as follows: if one brings the average mass of a star and of a spiral nebula into the scheme, one gets further clusters of numbers in the neighbourhood of the $1\frac{1}{2}$ and $1\frac{3}{4}$ powers of 10^{39}. From the foregoing ideas one would expect these to increase at the rate of the $1\frac{1}{2}$ and $1\frac{3}{4}$ powers respectively of the rate of increase of the 10^{39} cluster. This would enable one to calculate the rate of increase in the average mass of a star and of a spiral nebula, and hence also the rate of increase in the average number of stars in a spiral nebula.

Prof. W. H. McCrea, Queen's University, Belfast

Dr. H. Dingle's objection to "modern Aristotelianism" seems to be itself what he would call Aristotelian rather than Galilean. For a truly Galilean point of view would be to observe whether Eddington, or Milne, or anyone else, can in fact deduce properties of the physical world from a knowledge of "the system of thought by which the human mind interprets to itself the content of its sensory experience". Should it turn out that such a deduction is possible, the fact would be a new and exceedingly important experimental result, throwing fresh light upon the relation of the "physical world" to the human mind, and worthy of the attention of all true Galileans. On the other hand, to say that, "Nature nothing careth whether her abstruse reasons and methods of operating be, or be not, exposed to the Capacity of Men," is to assert something about Nature which is meaningless in regard to the experimental observation of Nature; by definition, man can experiment or theorize only about that which *is* exposed to the capacity of men—perhaps a trivial remark.

What Dr. Dingle has done is to reopen the question of the relation of mathematical physics to experimental physics, since he claims to detect a new and perverted point of view in the former. Now a system of mathematical physics, apart from the alleged perversion, is the working out of the mathematical consequences of certain hypotheses. The worth of the theory is judged on one hand by the fewness and simplicity of its hypotheses, and on the other by the closeness of the agreement of its predictions with the results of observation, and also the number of phenomena which it can so predict from the one set of hypotheses. Incidentally, some misunderstanding seems to arise because, for mathematical convenience, the hypotheses are generally stated as axioms, postulates, or 'laws', since the purely mathematical part of the theory is not concerned with their truth, in any sense, but only with their mutual consistency. Newton's laws of motion, and the principle of relativity, are examples of the hypotheses of two such theories.

Mathematical physics advances then, in one direction, by reducing the number of its hypotheses. This is well shown by the examples quoted by Dingle. Newton's theory was based on the hypothesis of his laws of motion and *also* upon implicit hypotheses about space and time. General relativity replaced this dual set of hypotheses by a single set. There is now "no such thing as a body in space, but matter is an aspect of the space-time structure" (Veblen and

Whitehead). Also the number and accuracy of the physical predictions were thereby increased. Milne next gives us a theory with still simpler and more easily apprehended hypotheses framed in terms of the equivalence of observers. The emphasis is on this equivalence, rather than on the cosmological principle as a property of the universe, as suggested by Dingle. Also, once again the number of phenomena brought within the scope of the theory has been increased. I think it is fair, in the present state of the theory, to class Milne's equivalences of observers (there are two kinds of equivalence specified) with Newton's laws, or the principle of relativity, as basic hypotheses of a system of mathematical physics; then this system falls naturally into place in the historical development, without being guilty of the type of heresy suspected by Dingle.

However, there is one significant feature in Milne's theory which must not be overlooked. The constancy of the velocity of light was a hypothesis in some formulations of special relativity theory. In Milne's theory it becomes a *convention*. This possibility, that a hypothesis might be discovered to be a convention, or that the theory might be so readjusted that it becomes a convention, was clearly shown by Poincaré in "La Science et l'Hypothèse". There are actually other examples as well in Milne's work.

This leads us on to inquire how far back this process of reducing hypotheses may be pushed. Now there is one set of 'hypotheses' implicit in all these theories. They all inevitably postulate or spring from the processes of human thought. Is it then possible that we may dispense with all other hypotheses, that is, that all other hypotheses will be revealed as conventions of thought or the expression of thought? Eddington's theory, presented in the "Relativity Theory of Protons and Electrons", and referred to by Dingle, may be regarded as, in fact, an effort to do this. The scientific attitude is, not to cavil at the attempt, but to see if it is successful. The theory is still too new for a consensus of scientific opinion to have been expressed; it is the purpose of this note merely to suggest that it is in harmony with the historic evolution of mathematical physics*. I fear, however, that I may have intruded into a region where angels might well fear to tread.

---

* Some of these ideas were developed in an inaugural lecture on "Mathematics and Cosmology", before the Queen's University on October 25, 1936.

Prof J. B. S. Haldane, F.R.S., University College, London

DR. DINGLE's spirited attack on Prof. Milne and Sir Arthur Eddington, in NATURE of May 8, will inevitably excite some sympathy among workers in sciences such as biology, where chains of reasoning are shorter than in cosmology. If Milne really attempted "to derive the laws of dynamics rationally —without recourse to experience", he would perhaps merit the title of traitor which Dingle awards him. But in actual fact his cosmological principle is based on the hypothesis that observers on the earth are not unique, and that observers on other stars would form a world-picture similar to our own. Now this hypothesis would have appeared fantastic to Aristotle, Ptolemy or St. Thomas. It is based on the deduction from astronomical observations that our own sun is one of a very large number of stars in one of a very large number of galaxies. The fact that it can be used as a basis for dynamics is remarkable, but Milne certainly did not frame it "without recourse to experience".

Similarly Eddington states that "An intelligence, unacquainted with our universe, but acquainted with the system of thought by which the human mind interprets to itself the content of sensory experience, should be able to attain all the knowledge of physics that we have attained by experiment". May be, but the system of thought in question happens to be determined, at least to a considerable extent, by the sensory experience. If Sir Arthur Eddington's entire sensory experience had been confined, say, to listening to the music of Bach, I venture to suggest that his system of thought would have been different. Actually this system is a highly specialized social product. I doubt whether the system of thought employed by the Australian aborigines to interpret their sensory experience would be so sound a basis for theoretical physics as that current in Cambridge.

However this may be, I trust that Dr. Dingle's article will not prevent biologists and geologists from studying Milne's cosmology, which, if accepted as a working hypothesis, will profoundly affect their sciences. For example, kinematical time, which is finite in the past, appears to be appropriate for describing chemical events, whilst many physical phenomena, such as the earth's rotation, proceed uniformly on a dynamical time scale which is infinite in the past, and corresponds to the logarithm of the kinematical scale.

Now many of the properties of matter are relations between chemical and physical events. For example, a given mass of a particular mixture at a certain temperature and pressure generates so many ergs per second. Clearly such properties of matter must change with time if Milne is correct; and $1\cdot5\times10^9$ years ago on the kinematic scale they may well have been sufficiently different to make life as we know it impossible. The conversion of chemical into kinetic energy is an essential feature of animal and even plant life; and in terms of our ordinary dynamical units this was, according to Milne, less rapid in the remote past.

There was, in fact, a moment when life of any sort first became possible, and the higher forms of life may only have become possible at a later date. If this is accepted, it cannot but alter our conceptions of evolution. Similarly a change in the properties of matter may account for some of the peculiarities of pre-Cambrian geology.

It is to be hoped that Prof. Milne and his colleagues will work out the secular changes in properties of matter such as density, rigidity, viscosity, surface tension, conductivity and the like, which may be expected to follow from his cosmological principles. If the results serve to illuminate the history of geological and organic evolution, we shall be kept too busy to find much time to blame him for a perhaps unduly idealistic account of their origin.

Dr. Harold Jeffreys, F.R.S., St. John's College, Cambridge

Dr. Dingle's article in Nature of May 8 seems to me an excellent statement of the position, and I am in full agreement with it. It is curious that advocates of the views criticized in the article usually refer to Mach, a large part of whose work was devoted to attacking the 'inherent necessity' view of causality and to showing how the laws of mechanics, then and usually still taught as a deductive science, were derived from experimental considerations. The principle of the rejection of unobservables, which is a practical working rule of induction, has now become misapplied, so that anything that an author does not wish to talk about can be disposed of by being called 'unobservable', however clearly observable it may be; and 'unobserved so far' and 'unobservable' are taken to mean the same thing, thus denying that there can be any knowledge that we have not already.

Milne[1] remarks that "the laws of dynamics are exact and simple, and hold good, because they are logical inferences from axiomatic definitions, obtained by a fairly short deductive train of thought. It is thus no longer necessary to appeal, as a warrant for a belief in the 'truth' of these laws of nature, to the so-called 'principle of induction', which has never been satisfactorily stated, much less demonstrated . . . observation vindicates, not the truth of the theorems . . . but the applicability of the definitions to the things occurring in nature".

We may admit the legitimacy of giving definitions and axioms as intuitive suggestions, working out the consequences deductively, and then testing the results by comparison with observation. But, as Whitehead and Russell point out, a definition depends for its validity on the existence of the thing defined, and therefore requires either a postulate or an existence theorem. It is perfectly possible to write down a definition of a plane equilateral right-angled triangle, but that is not the end of the matter. Where the existence has to be tested by experience the postulate depends on experience for its verification; and without a principle of induction there is no reason to suppose that it is true in any instances beyond those yet discovered. The fact that the principle of induction cannot be demonstrated from the axioms of logic has been known for centuries; but that merely shows that additional axioms are necessary. The axioms of logic also cannot be demonstrated; the great achievement of Whitehead and Russell was to reduce their number. Without using induction, Milne and Eddington could not order their lives for a day, and what they are really asserting is that they are entitled to use special axioms in physics, for which no need has been shown.

As for the statement of the extra postulates needed for a theory of induction, the essentials are better stated in Karl Pearson's "Grammar of Science" than in any other work known to me. Following on Pearson's lines, I think that I have given a set of simple postulates that will enable any type of observational data to be assimilated into the theory, without any need to assume that different fundamental principles of learning are needed in different subjects[2]. Other systems have been given by Prof. R. A. Fisher and other statisticians. Enough has been said already about the differences between these. The important point at the moment is that they are all satisfactory in the senses that (1) they do not treat any hypothesis as *a priori* certain; (2) they provide methods of choosing between hypotheses by means of observations; (3) they give estimates of the parameters involved in any hypothesis consistent with the observations; (4) they recognize that decisions made by them will sometimes be wrong, and give estimates of, alternatively, what degree of confidence we can reasonably attach to a decision, or how often, supposing that we use the rules regularly, we may expect the decisions to be right; (5) they all contain provision for correcting wrong decisions when observations become capable of giving further tests, thus recognizing that scientific progress is by successive approximation.

I should expect the decisions by my methods to lead to the correct decisions most rapidly, because the method contains more explicit provision for allowing for the whole of the data; but many rules given by Fisher, and others accepted by him, are of exactly the same form as mine and would in practice be used in the same way, while in other cases where there are differences the actual limits recommended are such that it would be extremely rarely that the decisions would differ in any specific application, and then we should both be doubtful. I should much prefer Fisher's system to any that asserts that only one hypothesis is to be considered at all, and, apparently, that a subject is meaningless until its laws have been predicted in terms of this hypothesis.

In one respect the position is even worse than is stated in Dr. Dingle's article. An author's preference for what he believes to be a deductive system may lead him to omit arguments that tend in favour of his main thesis. Einstein's theory was not the first explanation of the excess motion of the perihelion of Mercury. A completely satisfactory theory, as it then appeared, of the motion had already been given by Seeliger, attributing it to the attraction of the zodiacal matter. This accounted also for the excess motion of the node of Venus, which is 3·5 times its standard error, and was not explained by Einstein's theory. A larger random error would be expected to occur about once in 2,500 times; even allowing for the fact that the residual is selected as the extreme one out of 15 we should still not expect it more than once in 170 times. Newcomb had such confidence in this determination that he proposed to use it to determine the solar parallax dynamically. Yet writers on relativity all say that the residuals are perfectly satisfactory. De Sitter's last reference to the subject[3] gives a recalculation, which increases the residual, but he calls Newcomb's standard errors probable errors. Enough extra matter to account for the node of Venus would put the perihelion of Mercury hopelessly wrong. It might just possibly be a random error, but it was not legitimate to assert this until the alternative of additional matter near the sun was disposed of, particularly as such matter was seen. The question was whether there was enough of it. Similarly the refraction of a gas near the sun could account for the eclipse displacement of star images. Being prepared to take Einstein's theory seriously, but not being satisfied with the purely *a priori* arguments given for it, I obtained estimates of the quantity of matter present from its observed luminosity, and found that it would not account for 1/100 of the observed effects[4]. Consequently Einstein's theory was the only one suggested that was in accordance with the facts.

Now the remarkable thing is that, so far as I am aware, no exponent of relativity has ever mentioned this work or any improvement on it, the possibility of which I fully admit. It is apparently considered satisfactory to give a purely deductive theory from premises that are capable of being questioned, leaving with only a passing mention a residual with a natural alternative explanation that would not ordinarily be exceeded more than once in 170 times; while the fact that the theory is the *only* suggested one that is observationally tenable is not thought worth mentioning. Or is it not mentioned *because* mention of it would admit that the postulates of the theory are not *a priori* certain? In any case mention of the matter would make the theory more convincing to those who are not dazzled by the mathematics.

Milne similarly is trying to combine the phenomena of light and gravitation into one system, but the only observed facts that appear to involve the velocity of light and the constant of gravitation together, the three Einstein crucial tests, are postponed for treatment to an indefinite date as minor effects. As most of his work rests on the hypothesis of the universal applicability of the Lorentz transformation, I should expect it to lead to the same predictions as Silberstein's, which *a priori* seemed as reasonable as Einstein's, but made the perihelion of Mercury go round the wrong way and had to be dropped when there appeared to be no reasonable possibility of enough extra matter to put it right[5]. At all events, there is still no reason to believe that Milne's theory will lead to the correct predictions.

I think the source of the trouble is the belief that there is some special virtue in mathematics. Instead of being regarded as what it is, a tool for dealing with arguments too complicated to be presented without it, it has become emotionalized to such an extent that many people think that nothing but mathematics has any meaning; whereas the opinion of some of the best pure mathematicians is that the characteristic feature of mathematics itself is that it has no meaning. Russell has described mathematics as "a subject where we do not know what we are talking about, or whether what we are saying is true". Its function in science is to connect postulates with observations. The utility of deduction is that in investigating the consequences of a well-supported law it is a convenient approximation to induction.

Dr. Norman R. Campbell

SCIENCE, as Dr. W. H. George has lately told us, is the activity of scientists; it has no heresy but orthodoxy. Accordingly when we find fellows of the Royal Society indulging in speculations that would have been dismissed as fantastic (or, even worse, metaphysical) a few years ago, the proper course is not to accuse that body of disloyalty to its seventeenth-century traditions, but to inquire why new interests have appeared so suddenly. The answer to that question is very simple: the new developments could have been (I think they were) predicted before they occurred.

Science (or at least physics) has long consisted of two distinct but complementary activities. The distinction between them has been obscured, because they were practised by the same individuals; but now that physicists are rapidly segregating into experimenters who evolve no theories and theorists who make no experiments, there is no excuse for ignoring it.

One activity consists in the discovering of demonstrable experiments and their description (so far as that is possible) by laws. Its procedure is induction, which is the building up of experiments of higher rank out of elements which are themselves experiments of lower rank. It is peculiar to science; its products grow by accretion with little secular modification; it is the source of the practical utility of science.

The other activity consists in devising theories to explain the laws. Explanation is not peculiar to science, and is subject to fashion. But it always consists essentially in some substitution of ideas more intrinsically acceptable for ideas less acceptable. The process can be analysed into three steps: the formulation of hypotheses involving the acceptable ideas alone, the deduction of consequences from these hypotheses, and the translation of these conclusions into propositions concerning the less acceptable ideas by means of a 'dictionary'. The peculiarity of scientific explanations is that they often (not always) predict new laws in addition to explaining old ones.

Until the end of the nineteenth century, the hypothetical ideas introduced by scientific explanations owed their acceptability to an analogy with terms used in stating laws, an analogy so close that the same word was usually used for both, and the distinction between them was overlooked by the careless. But the more thoughtful always realized that (for example) a statement about the density of water was nothing but an imperfect way of describing a demonstrable experiment, while a statement about the density of the æther meant something that could not be demonstrated by experiment at all.

At the beginning of the twentieth century, laws were discovered for the explanation of which no 'mechanical' theory of this type could be found. At first it seemed as if the second activity of science might have to be abandoned. But propositions were found from which, by the aid of dictionary, laws could be deduced and actually predicted. They resembled the conclusions of a mechanical theory in this, and also in involving ideas (such as a wave-function or an imaginary co-ordinate of space) that had no relation, apart from the dictionary, to any demonstrable experiment; they differed in not being deducible from any intrinsically acceptable hypothesis.

If the older structure of science was to be restored, hypotheses had to be found from which these propositions could be deduced. Since the propositions were mathematical and invented by mathematicians, it was inevitable that the hypothetical ideas should be highly abstract and that the acceptability of the resultant theory should lie in a conformity to mathematical ideals, that is to say, in the rigid deduction of elegant conclusions from the minimum of self-evident axioms. The work that makes Dr. H. Dingle so indignant appears to me a laudable attempt to solve this problem, and, if I read his "Principles" aright, so it does to Prof. Dirac. If the attempt succeeds, experimenters will not, of course, gain the satisfaction that they derived from mechanical theories—that appears a vain hope; but even the horror of logical rigidity that inspires the average experimenter may permit him to prefer a logical theory to none at all. Moreover, it is not necessary that all traces of the old analogies should be lost. It is noteworthy that both Dirac and Milne introduce as fundamental an idea closely analogous to the agreement between observers, which is implied in the conception of a demonstrable experiment. (Here, of course, Dr. Dingle is definitely wrong. If only a single observer existed, neither the Doppler nor any other experimental effect could be detected; he would have no means of distinguishing fact from his individual illusions.)

The rest of Dr. Dingle's objections appear to arise partly from a trivial dislike of the term universe —which I share, partly from a flat denial of the duality of physics and a persistent confusion of theories and laws. If he does not deem it important to observe the distinction between what is and what is not demonstrable experiment, surely he should welcome a movement to amalgamate the Royal with the Aristotelian Society.

By Prof. L. N. G. Filon, C.B.E., F.R.S., University College, London

WITHOUT necessarily endorsing all that Dr. Dingle has written about "the New Aristotelianism", one may be permitted to welcome a protest against the modern tendency in physics to proceed from abstract and universal *a priori* mathematical theories, which seem to spring up nowadays in disconcerting numbers.

The real trouble seems to be that, instead of starting from the facts of observation and gradually building up by induction particular laws, which may or may not eventually be linked up, some men of science appear to think that they can solve the whole problem of Nature by some all-inclusive mathematical intuition. What they are really doing is not to explain Nature, but to explore the possibilities of the human mind. If Prof. E. A. Milne's statement, which Dr. Dingle quotes, is really to be taken literally, it would probably lead to the conclusion that all science reduces to pure nominalism, a view to which few would care to subscribe.

Surely it is time that we got back to the more secure, if more pedestrian, methods of the nineteenth century. I seem to remember a phrase, to which at any rate a good deal of lip-service used to be paid, about hypotheses "which were crushed in the solitude of the study". Judging by much of the scientific literature which gets published nowadays, something seems to have gone wrong with the crushing-machines.

Prof. W. Peddie, University College, Dundee

THE recent timely strictures (NATURE, May 8, p. 784) made by Dr. Dingle on modern Aristotelian tendencies in some theoretical investigations in physics suggest that a change in the line of (metaphysical) attack on physical problems might be of value.

For example, if we *postulate* (1) an at least four-dimensional plane universe, (2) motion in our three dimensional part of which is responsible for our idea of space, while, (3) constancy of speed of an observer in the four dimensions originates our idea of absolute time, (4) local time is measured out by the fourth dimensional component of speed, we can deduce the necessity for special relativity.

By modification of some of these postulates we can revel in general relativity.

The difference in effect is that we can blame the objective physical universe for the formal laws of thought, instead of the laws of thought for the structure of the universe. We can escape from Aristotle and get back to Galileo and Newton.

Prof. R. A. Sampson, F.R.S., Royal Observatory, Edinburgh

I HOLD that we are limited beings, limited as regards our senses, which are our only means of understanding the world, and limited also in time. We cannot enlarge our reliance upon our senses. The microscope, for example, is taken as a means for extending our observations. But any observations made must be afterwards interpreted by the senses, so that we can infer what they represent. We are limited, too, in regard to understanding any communicator. Anything we hear must pass through two barriers: first, whether it expresses correctly what the communicator feels—many professional writers have complained of the difficulties of expression—and second, whether we can understand it. Many cases will occur to anybody when these limitations prove a total blank. I hold all this so strongly that I am not even interested to discuss the question with anyone who holds the opposite view. That means that I am *not* a "modern Aristotelian". But I doubt whether anyone is. Even in the case of those whose words may bear the fair conclusion that they *are* modern Aristotelians, and suppose that they *are* independent of experience, I think that their practice belies their words. It is a very difficult thing even to express oneself so as always to be consistent. Even with the advantage of consisting of the same skin and bone, one often says contradictory things. Then there is the certainty that the statements are not absolute, but depend upon the refinement of our means of expression. The same problem of understanding the world must present itself to primitive peoples, who have no adequate means of expressing their meaning.

The means that are supplied to us provide a distinctly partial means of understanding the world. The senses are very crude, and can only be extended in the way shown above. We cannot tell what time is. Probably it is no more than a physical displacement, like other physical displacements. If this is so, Nature, which depends upon the isolation of events, disappears as an entity, for it depends upon the separation of the time co-ordinate from the others. As I have remarked in another place, it would be a very convenient thing to foretell the future—even to foretell it roughly. We have memory, but not foresight. Descartes' dictum "*je pense, donc je suis*" ought to be supplemented with "*I thought and so I was*", for this is constantly used for prediction, in fact it supplies the second proposition upon which we can base a third. Indeed most of our devices seek to extend the intellect into the future. Ignoring the primitive claims to do so—like 'second sight'—the rules of logic are just such another device, a more subtle device but of just the same sort. For where logic works, it offers to tell us what will happen in another place and time, of which, *ex hypothesi*, we have no experience. Of course a large part of logic is merely explanatory, a mere unfolding of what is implied in the statements. Take, for example, mathematics. The statements found in Euclid are contained in the definitions, postulates and axioms. They are mere statements. None of them can be proved or disproved, and their interest is derived from the way in which they accord with the external world. All the rest is a process of unfolding; and so for other cases—all follow the same model.

To resume, however, the question of predicting the future. It is the greatest error that mathematics makes, that it slurs the distinction between the past and the future—the quantities that it handles being timeless. Of course, in a minor way, the distinction *is* recognized in thermodynamics, in the proposition that entropy must always increase in the future. But this is the sole case, and it might even be traced to a formal expression of the proposition that there is a notorious difference between the past and the future.

The fact is that Nature is becoming enormously complicated—almost too complicated to use. In the old days the same man might be a doctor of medicine and an astronomer. The same word was used to describe an astronomer as an astrologer. Those days are past. We must now be content with theories which express the *essentials* of what we wish to express; to take again an instance from mathematics, the ordinary theory of rotating liquids, which alone is workable, is indefensible hydrodynamically; yet it expresses what is essential of 'centrifugal force', and would collapse without it. So it contains what is requisite, and we extrapolate from it confidently. All statements that we reach are extrapolations from experience, and, as such, their interest depends upon their being approximately true. With our imperfect means of recognizing the truth, we cannot expect any statement to be more than approximately true.

What then is 'observable'? Ought we to limit theorems strictly to what is observable? To confine oneself to what is observable, seems to mean confining oneself to mere verification of experience. For before it is experienced, a prediction is of no value, and after it is experienced, the theory that has led us to look in the right place, must be replaced by the experiment made. Expectation, in fine, depends upon theory. The Brownian movement, for example, must be shown to accord with expectations. A theory will be more or less extensive according to the man that frames it. Some will be complicated by things which must for ever remain unobservable. Some will be directed to a single point. Some will be very extensive, like the law of gravitation or the theories of general dynamics. All are mere guesses at truth. This seems to supply the point of reconciliation for framing a theory independent of experience, such as is denounced in Dr. Dingle's article, and also with the work of a poet or other humanist, who gives us at most a number of illustrative cases.

Prof. C. G. Darwin, F.R.S., Christ's College, Cambridge.

THE most interesting moral to be drawn from Dr. Dingle's article has nothing to do with his detailed criticisms of the theories of the "Aristotelians"; but raises the matter of the curious relationship which at present subsists between metaphysics and science. This has somehow gone wrong. On one hand, we have the philosophers claiming that their metaphysics underlies all possible knowledge, so that they may tell us what we are allowed to think; surely at first sight one would have expected that they could settle the present controversy with authority. On the other hand, we have the men of science, each with his own philosophy, most usually formed without any professional study of the subject, often held with a most polemic enthusiasm, and showing the wildest divergencies.

The noticeable point is that these contradictious views do not seem to matter in the very least; we none of us doubt that both Dingle and Milne will help on the progress of science, and that the advances they make will have scarcely anything to do with their opposite metaphysical ideas. Each of us must have a philosophy of things in general, and this will include our philosophy of physics; it may be extracted from us with the methods of Socratic dialogue by some more expert philosopher, and the inquiry will usually reveal inconsistencies and impossibilities in our system, so that we shall end by wanting to do to our inquirer what the Athenians did to Socrates. That is not the point; for the fact remains that it is the science and not the philosophy that matters, and that most men of science do not find it worth their while to read the works of metaphysicians. Is not the salient fact about the philosophy of science that no professional philosopher can write a book that a man of science wants to read? Ought there not to be a meta-metaphysics which would bring a message of comfort telling us not to bother about our philosophy—a command most of us already obey—because we can get on with our business without it? A book on this subject would show what a lot of things there are that do not matter much, and it would have the advantage that *a fortiori* no one at all need read it.

Coming down to the details of the controversy, Dr. Dingle seems to want to hamper speculation by forbidding all but the most pedestrian forms of inductive reasoning. It is surely hard enough to make discoveries in science without having to obey arbitrary rules in doing so; in discovering the laws of Nature, foul means are perfectly fair. If Dirac is not to be allowed to conjecture the age of the earth from certain curious numerical coincidences, then Maxwell committed quite as great a crime in conjecturing that the velocity of light was the same thing as the ratio of the electric and magnetic units. It is absurd to maintain that such guesses are illegitimate. On the other hand, some of Dingle's antagonists have held the view that all Nature is contained in our own minds. Surely even if this is true it is a very unimportant statement. Is it not like asserting that anyone who knows the rules of chess has the whole game in his mind, and therefore will always win?

G. J. Whitrow, Christ Church, Oxford

Dr. H. Dingle, in his recent article "Modern Aristotelianism", not only attacks the particular methods adopted by contemporary mathematical investigators in relativistic cosmology, but even refuses to admit that this subject is worthy of scientific investigation as it is based not only on experience but also on reason. This point of view, like most *anti-intellectual* philosophies, is based on a pure myth—in this case a mythical interpretation of the history of scientific method.

Since modern scientific method originated with the Copernican theory of the universe, let us consider the attitude which Dingle, as an empiricist, would have adopted towards the then new cosmology. With the instruments of the day, there were no known celestial phenomena which were not accounted for by the Ptolemaic system. Consequently, he would have regarded Copernicus's system as a "pseudo-science of invertebrate cosmythology", and would have preferred the laborious Ptolemaic inductions built up through centuries of patient observation, since to the many serious objections which were advanced against his theory Copernicus could only plead mathematical simplicity. It follows that Dingle himself would have been in the 'Aristotelian' camp.

It is well known that the driving force of Kepler's work was his belief in the existence of mathematical harmonies in Nature. Similarly, Galileo regarded mathematics as the appropriate instrument for scientific investigation. "We do not learn to demonstrate from the manuals of logic but from the books of demonstration which are the mathematical"[1]. It is of course true, as Dingle points out, that he said "Nature nothing cares whether her reasons and methods of operating be or be not understandable by man". This, however, as Dingle does *not* point out, was merely an expression of his rejection of Scholastic *teleology*. In point of fact, Galileo's whole life's work was based on the firm belief that Nature *is* understandable by man. "Philosophy is written in that great book which ever lies before our eyes—I mean the universe. . . . This book is written in the mathematical language"[2]. Indeed there is little doubt that Galileo regarded mathematical demonstration as an *a priori* method of reaching truth. As Mr. J. J. Fahie has shown, "in order to be able to demonstrate to his opponents the truth of his conclusions he had been forced to prove them by a variety of experiments, though to satisfy his own mind alone he had never felt it necessary to make any"[3].

We thus find, *pace* Dingle, that the methods of modern cosmologists are not so opposed to those of Galileo as he would have us believe. The three fundamental rules on which scientific investigation has proceeded since the days of Copernicus are: (1) belief in the simplicity and uniformity of Nature; (2) belief in the possibility of a mathematical description of Nature; (3) gradual discarding of all anthropocentric concepts. In particular, the last rule has recently found expression in the principle of relativity which, in general terms, can be said to signify the autonomy of individual points of view in the description of Nature. Prof. Milne's concept of equivalent observers is one way of making this idea precise. Relativistic cosmology, as based on these three rules, is therefore in the true spirit of all natural philosophy since the Renaissance.

In conclusion, I should like to direct attention to the extreme outburst of irrationalism which leads

Dingle to declare that "Even mere verbal heresies such as the statement that science is based on faith in an 'Order of Nature' have been few and harmless; we may have said such things, but we have always acted as though Nature might nothing care for what our minds call order". Actually, the exact opposite has been the case, for, as Prof. Whitehead points out, "there can be no living science unless there is a widespread conviction in the existence of an Order of Things and in particular of an Order of Nature"[4].

Fr. W. McEntegart, S.J., Heythrop College, Chipping Norton

Dr. Dingle's contribution to Nature of May 8 is a notable portent, and his challenge is happily juxtaposed with Lord Rayleigh's article on "Optical Contact". The inarticulate many who are pining for a return to reality in physics must be heart-stirred to find themselves possessed of such a champion. But one small protest must be entered. Why does Dr. Dingle dub his unrealist targets Aristotelians? Let him, if he so wishes, name them Kantians, Hegelians, or even Fichteans. But Aristotle and every loyal Aristotelian are on his own side. No experimenter, aiming, in Dr. Dingle's own words, "at rationalizing observations", ever did, or ever can, dispense with philosophy. Sound metaphysics will not compensate for an insufficiency of observation, culpable or otherwise; but the absence of a solid metaphysical foundation will vitiate all attempts to rationalize observations, howsoever abundant they be.

The fiction that the peripatetic philosophy is an airy tissue of aprioristic deduction should by now be outworn. It is, itself, a rationalization of experience, firmly keyed to reality. It is the mould the impress of which is still unmistakable in the language and thought of the civilized world, and some serious acquaintance with it would have a salutary and sobering effect on the 'universe' fabricators of whom Dr. Dingle complains. Sir Arthur Eddington, for example, would find it a philosophy ample enough to accommodate all the intuitions he can command, and might cease to claim for epistemology a super-comprehension of the existing physical world.

Dr. Dingle bewails the new 'cosmolatry' engendered "by metaphysics out of mathematics". If, in the spirit of true science, he would but disregard the traditional taboo, and discover for himself what metaphysics is, he could not impute such disreputable offspring to so noble a sire: and is his confidence that "the theory of relativity appears to be the *innocent* cause" (italics mine) securely founded as touching the innocence? The 'hall-marks' alleged recall a wise saying of Whitehead's, "The history of science is strewn with the happy applications of discarded theories."[1]

Dr. H. Stafford Hatfield

Dr. H. Dingle's rather drastic remarks concerning present-day physical speculation seem to overlook one main factor in the progress of science—the capture of young minds of the highest order of genius. The genius of every age turns mainly in that direction which offers the greatest scope for the creative imagination. Since the time of Galileo, physics has seemed (however wrongly, according to some philosophers) to promise an eventual view of all time and all space, just as biology seems to offer an approach to the secret of life and mind. Most of their greatest exponents have combined a vigorous care for fact and sound reasoning with a delight in imaginative speculation. The great army of lesser workers, experimental hobbyists, mathematical cross-worders, even competitive careerists, find their world brighter for the speculative flights of men who, furthermore, often beat each at his own game.

A science kept strictly to facts and formulæ by 'pale Galileans' would recruit very few geniuses, fewer rank-and-file workers, and—fewer endowments!

Prof. G. Dawes Hicks, emeritus professor of philosophy, University College, London.*

I find it difficult to discuss profitably Dr. Herbert Dingle's article, because, although I think there is a certain amount of justification for the protest he raises against some current ways of presenting theories of the physical world, yet it seems to me he lays the blame upon the wrong things, and draws a contrast for which there is really no warrant.

Let me dwell, first, on the latter point. There were doubtless bastard "Aristotelians" at the time of the Renaissance, as there have been bastard "Galileans" since. But no genuine follower of Aristotle would have admitted for a moment that "Nature is the visible working-out of general principles known to the human mind apart from sense-perception", or that "reason could, apart from sense, dictate the course of experience". As a matter of fact, in handling the question how we come to reflect on general principles, Aristotle consistently maintained that it was by induction from experience. The human intellect was not supposed by him to operate *in abstracto*. On the contrary, general principles came to be apprehended in and through the matter furnished in sense-perception. Aristotle never questioned the validity of the data of sense. Indeed, the human mind or consciousness, as he conceived it, was just a capacity of becoming aware of the facts presented in sense-perception, and of dealing with them by certain processes which constitute the mental life itself. At the basis of all these was the process of sense-perception (αἴσθησις), and sense-perception had for its objects individual things (τὰ ὄντα). Not only so, sense-perception was not viewed as merely passive receptivity. It was a natural discriminative faculty

---

* This contribution, and another by Prof H. Levy, were not received in time to be submitted to Dr. Dingle for possible comment. Prof H. Levy's article arrived after this Supplement had been made up, and is printed on p 1025 of this issue.

(a δύναμις κριτική). Out of it, in its cruder forms, memory comes to be, and out of frequently repeated memories of the same thing experience (ἐμπειρία) is developed, from which again "originate the skill of the craftsman and the knowledge of the man of science". "These states of knowledge are neither innate in a determinate form, nor developed from other higher states of knowledge, but from sense-perception" (*Post. An.*, ii, 19, 100^a). The human subject is capable, that is to say, of comparing experiences of various kinds with each other, and of concentrating attention upon one characteristic of a concrete thing to the exclusion of other characteristics. Thus, on the basis of familiarity with concrete things, the human subject can build up an abstract science.

Aristotle certainly distinguished between the way in which we come to be aware of general principles and the evidence there is for their truth. He did not fall into J. S. Mill's error of supposing that the instances used in an induction serve not only to lead us to recognize the general principle they exemplify but also to guarantee likewise its validity. Aristotle held, indeed, that the ultimate principles of science neither permit of nor require proof. When through induction the scientist has attained to such a principle, reason enables him to see by a kind of intellectual intuition that it is true. We may, or may not, acquiesce in this view; but, at any rate, it does not involve the inconsistency of first pronouncing induction by imperfect enumeration to be (as it obviously is) fallacious, and then assuming that the ultimate premiss of natural science is established by this fallacious method.

That Aristotle failed to recognize the importance of observation in scientific investigation is simply contrary to all the information that has come down to us. In biology particularly, whether we have regard to his powers of observation, his collation of what others had observed, or his theoretical deductions therefrom, we cannot but be struck by his remarkable achievements. "All the general propositions which he expresses are", said Cuvier, "inductions, resulting from observation and the comparison of particular facts; never does he impose a rule *a priori*". "Linnaeus and Cuvier have been my two gods", wrote Darwin, "though in very different ways, but they were mere schoolboys to old Aristotle". It is worth while mentioning here a significant example of the trait we are referring to. After having discussed in detail the manner of the generation of bees, Aristotle adds, "the facts, however, have not yet been sufficiently grasped; if ever they are, then credit must be given rather to observation than to theories, and to theories only if what they affirm agrees with the observed facts" (*D. G.*, iii, 10, 760^b).

There was, indeed, among the ancients generally no lack of appreciation of the need of careful and accurate observation; and they probably made more use of experiment than appears at first sight from the accounts we have of their work. Not then in this respect did their outlook differ from ours. The acceptance of the Copernican system may, from some points of view, be looked upon as the beginning of the modern scientific era. Yet clearly it was not merely by patient observation of the facts that this revolution came about, for such observation by itself could have led no one to question what seems, on the face of it, to be an obvious fact, that the sun moves round the earth. Rather was the Copernican hypothesis adopted because it enabled the movements of the heavenly bodies to be expressed in simple mathematical formulæ. But, so far as mere observation of the facts was concerned, there was nothing to suggest that the simplest explanation could be accepted as the true one. It was because it had come to be seen that science requires, in order to get under way, the recognition of some theory of what explanation means, that the Copernican hypothesis in the long run prevailed. It is noteworthy that Galileo himself expressed his admiration for that trust in reason which induced Copernicus to adhere to his view, in spite of its apparent discrepancies with the facts, until more delicate observations in the end confirmed it. The great claim of Copernicus to fame rests, he said, upon this, "that he did constantly continue to affirm (being persuaded thereto by reason) that which sensible experiments seemed to contradict".

Now, this "rape of reason upon the senses", as Galileo styled it, really means that in order to make headway the scientific investigator is constrained to adopt, either explicitly or implicitly, as a necessary preliminary, some general philosophic view, good or bad, of the nature of things. "If science is not to degenerate into a medley of *ad hoc* hypotheses, it must", writes Whitehead, "become philosophical and must enter upon a thorough criticism of its own foundations." It is not because Sir Arthur Eddington and other writers on relativity approach their theme from a philosophic point of view, but because the particular philosophic point of view which they adopt so often evinces itself as thoroughly unworkable, that one finds their treatment unsatisfactory. For example, when it is laid down, at the start, that "the task of physical science is to infer knowledge of external objects from a set of signals passing along our nerves", or rather that "the material from which we have to make our inferences is not the signals themselves, but a fanciful story which has been in some way based on them", that "it is as though we were asked to decode a cipher message and were given, not the cipher itself, but a mistranslation of it made by a clumsy amateur", we are confronted not with a "new Aristotelianism" but with a theory of knowledge which leaves us gasping when we try to put its parts together. It is not a question, as Sir Arthur Eddington appears to think, between idealism and realism; neither on idealistic nor on realistic grounds could a notion of this sort be sustained. There are certain well-established truths concerning the nature of knowledge which simply put a view of the kind indicated altogether out of court. The unfortunate thing is that the excessive specialization of the present day renders it well-nigh impossible for the scientific investigator to keep himself abreast of what is being done in the fields of epistemology and the logical scrutiny of scientific method.

Deductive and Inductive Methods in Science: A Reply

By Dr. Herbert Dingle

LET me begin by removing misapprehensions. I did not, as Prof. J. B. S. Haldane suggests, attack Prof. E. A. Milne and Sir Arthur Eddington: "Milne", "Eddington" and "Dirac" were merely symbols to facilitate reference to certain passages of literature with which alone I was concerned. Nor did I award Prof. Milne the title of traitor. My point was that the present menace was *not* one of the ordinary cases of treachery to a cause; it was the creation, through the aberration of some of our most gifted minds, of an atmosphere in which treachery can flourish. I have the greatest respect for Prof. Milne, but I cannot speak too disrespectfully of the cosmological principle.

To Aristotle also let justice be done. The answer to Father McEntegart's question is that I called my "targets" Aristotelians because they have revived the fallacy maintained by those whom Galileo and Newton called Aristotelians and who never, to my knowledge, disowned the name. To avoid libelling Aristotle, I put the word in quotation marks at its first appearance.

Except in one instance, I will not comment on matters of history: the facts are open to anyone who is able and willing to read them without prejudice. But I feel that I must put in a mild protest on behalf of Newton. Referring to modern mathematical physics, Prof. W. H. McCrea tells us that "for mathematical convenience, the hypotheses are generally stated as axioms". I had noticed that, and I can see the convenience when one comes to interpret the results, though its advantage at other times escapes me. But it must be remembered that Newton's mathematics was much cruder than ours, and since he repeatedly said that he did not make, and strongly deprecated, hypotheses, the probability would seem to be that he meant what he said: and when you try to discover what he did mean by hypothesis, you find that it was something so like Prof. Milne's cosmological principle that, if you relied only on the effete process of inspection for comparing them, you would scarcely know the difference. It appears, therefore, that Prof. McCrea, in classifying Newton's laws of mechanics with Milne's principle, has credited Newton with a mathematical facility not available in his day.

Several questions have been raised relating to the theory of knowledge and such subjects, which interest me very much, but I must keep to the main point. If anyone is interested in my attitude to these matters, he will find it expressed in a book now passing through the press; having tried to be explicit in 100,000 words I do not wish to court misunderstanding in fifty. For the purpose of this discussion, therefore, I adopt the view that the aim of science is the discovery of the truth about Nature. I do not think those are the best terms of expression, but they are simple and familiar and are perfectly applicable here. The question is then whether we can discover the truth about Nature rationally without recourse to experience.

I am delighted at Sir Arthur Eddington's admission that "we can have no *a priori* knowledge of the universe". His further statement that "*Knowledge of the mass-ratio* (of proton to electron) *is not knowledge of an objective universe*", for all its italics, comes a little late to be impressive, for it is what a die-hard of the Galilean school has been vainly trying to tell him for years. Even so lately as in his "New Pathways in Science" he wrote (pp. 20–21) that protons and electrons have "the same kind of connection with human experience as . . . sticks and stones and stars".

Sir Arthur's new discovery confirms my statement that his philosophy lags far behind his instinctive ideas. Without any of his genius, I saw clearly nearly a decade ago what has been revealed to him only through the agony of giving birth to an intricate theory; my 'hunch' that there is a lot in the theory is accordingly strengthened. But since for one person who tries to understand it there are a thousand who are guided, or misguided, by his philosophy, I venture to assure him that his new vision does not include the requirement that conflict with the laws of Nature is impossible or unobservable. That is even farther from the truth than his earlier belief in universal indeterminacy, which presumably cannot remain undisturbed in the face of inviolable laws. However, all in good time: meanwhile, let me also have my italics—"*We can have no* a priori *knowledge of the universe*". *Vicisti, Galilei*!

Prof. Milne simply makes it more clear than before, if possible, that he is not concerned with science at all. He does not want to find out the truth about Nature; he wants to make a theory. "Systems are constructed which may or may not have their counterparts in the external world". We then appeal to observation "to discover theorems empirically" and "to verify the relevance of theorems discovered by inference from axioms". (I thought some observers tried to discover facts, but apparently I was mistaken; physics based on facts is "irrational and inexact".) But the appeal is really idle, for "theorems exist in their own right", which is by no means affected if observation should prove them irrelevant. We go on looking, presumably, through a kind of race-memory generated in the old days of superstition.

I have no objection to theorems existing in their own right, any more than to the Choral Symphony existing in its own right, but I should very much like to know by what right Prof. Milne steals a march on Beethoven by publishing his creations in scientific journals. He is not interested in the standard metre because it is "undefinable". It is a part of the external world, of course, but he does not want to know about the external world; definitions are all that matter. He writes about hypotheses because they can be defined as axioms, but he will not write about Nature. Since when has the Royal Society been dedicated to the study of definitions?

I am not, I repeat, trying to stifle newly-born methods of research; the situation is quite other. Let us see by an actual example what this theory is. It made its debut early in 1933 in a 95-page article[1] arising out of the problem of the apparent recession of the nebulæ. After four years, crammed with developments and amendments of the fundamental idea, the solution of the problem is reached; here it is: "Imagine a nebular nucleus joined to ourselves by a material bar, supposed rigid; would the end of the bar and the nebular nucleus separate? The answer is that they would if the bar is deemed rigid Deductive and Industive Methods of Science, etc. 2 on the kinematic scale but not if the bar is deemed rigid on the dynamic scale."[2] Everything depends, it seems, on what we "deem"; what, then, shall we deem the standard metre? Ah, we cannot say; that is undefinable. Well, perhaps not enough has been published yet; suppose we wait a few years longer? No, that will not do, for the question is settled already; this is the "solution of the much-disputed problem" (p. 345)—"we resolve the controversy" (pp. 328–9). And, indeed, Prof. Milne's problem *is* solved, because it is not a problem about Nature but about "axiomatic definitions" existing in their own right. On the *scientific* problem, which is concerned with the actual world, we get no help. I hope Prof. Haldane is not building too much on the possible contribution of the theory to the problem of organic evolution. When an observer in a spiral nebula can define an organism in terms of clock-readings, some light *may* be thrown on the clock. Since a non-observer on the earth can never define the standard metre in any terms, the prospect can scarcely be called bright.

I did not overlook Dr. H. Stafford Hatfield's point concerning the "delights of imaginative speculation" or "the capture of young minds". These practices, like armament racing, add to the joy of life, and the capture of young minds can be illustrated well enough (though more serious and equally relevant examples exist) by the last paragraph of Mr. G. J. Whitrow's contribution (p. 1008), in which he calls a statement of mine an "extreme outburst of irrationalism" because he has found a remark by Prof. Whitehead which exemplifies it. That before criticizing it all at he should have found a contribution to science by Prof. Whitehead or another that would collapse if one removed the presupposition of an "Order of Nature"; and that, if he had found it, he would have shown my statement to be inaccurate (contrary to fact) and not irrational (contrary to reason)—did not occur to him. Having been well captured, he has lost the faculty for distinguishing fact from reason, and, using Milne's device of "an extreme application of the principle of the economy of thought", he rushes into print in my support. Mr. Whitrow might have made brilliant and valuable contributions to science—and this is what kinematical relativity has made of him. Yes, it is fine sport, and may even bring endowments. If I were a rich would-be dictator, I would endow it myself.

Once more, I do not want to hamper speculation in the way Prof. C. G. Darwin suggests. I cited Prof. Dirac's letter not as a source of infection but as an example of the bacteria that can flourish in the poisoned atmosphere; in a pure environment it would not have come to birth, and we should still have had the old, incomparable Dirac. One may fly as well in pure as in foul air, and with better prospects. But my concern is with the general intellectual miasma that threatens to envelop the world of science, and I emphatically disagree with Prof. Darwin's opinion that it does not matter what you think about science so long as you advance it: as well say that it does not matter what you burn so long as you make a bonfire. If I never added a jot to science, but succeeded in discovering and making clear what science is doing, I should consider that I had served my generation at least as well as if I had discovered a new universe. In the last resort, this matters almost more than anything else. How many physicists to-day feel confident that they can read a statement concerning our ordinary everyday consciousness of time, for example, and say, not whether it is true or false, but even whether it is sensible or nonsensical, a serious idea or a clever hoax? The criterion for distinguishing sense from nonsense has to a large extent been lost: our minds are ready to tolerate any statement, no matter how ridiculous it obviously is, if only it comes from a man of repute and is accompanied by an array of symbols in Clarendon type.

If this state of mind exists among the *élite* of science, what will be the state of mind of a public taught to measure the value of an idea in terms of its incomprehensibility and to scorn the old science because it could be understood? The times are not so auspicious that we can rest comfortably in a mental atmosphere in which the ideas fittest to survive are not those which stand in the most rational relation to experience, but those which can don the most impressive garb of pseudo-profundity. There is evidence enough on the Continent of the effects of doctrines derived "rationally without recourse to experience". To purify the air seems to me an urgent necessity: I wish it were in other and better hands.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST ALBANS

Laboratory. In addition to the maintenance of standards of measurement and testing of instruments and materials, much research work has been done on these subjects and on others submitted by industry. A noise meter and an instrument for measuring the penetration of daylight into rooms have been devised. Light magnesium alloys of greatly increased strength have been produced, and the eight wind tunnels have been in full use. The use of protective coatings on steels liable to corrosion and the reasons for the superiority of certain oils as lubricants are being investigated, while the ship testing tank has been requisitioned for 78 per cent of the merchant shipping constructed in Great Britain.

Motion Pictures of Solar Prominences

VOL. 3, No. 1 of *Publications of the Observatory of the University of Michigan* contains a detailed description by R. McMath of the tower telescope of the McMath-Hulbert Observatory which has recently been built near Lake Angelus, Michigan. The telescope, which comprises a modified form of spectroheliograph ("the spectroheliokinematograph"), has been used to take successful motion pictures of solar prominences. A specimen film, taken in K_2 light and showing various types of prominences, was recently exhibited at one of the monthly meetings of the Royal Astronomical Society. The gradual movements of comparatively stable prominences, the eruptive motions of others, and the frequent occurrence of descending streams of prominence matter from points of origin above the chromosphere were beautifully shown (*The Observatory*, 85, April 1937). It may be noted that the founders and designers of the Observatory and its equipment, R. R. McMath, H. S. Hulbert and F. C. McMath, are non-professional astronomers. Acknowledgment is made by them in the present memoir for assistance received in advice, expert supervision and financial assistance during the building of their tower telescope.

The Zoological Society of London

"THE Zoo" progresses from strength to strength. A hundred years ago the then Earl of Derby announced that its income had mounted to £19,123; now it is £154,172; then the visitors numbered 363,392, now they are 1,962,122 plus another 484,453 at Whipsnade. The members who now number 8,307 were then 3,050. The stock of animals has increased slightly more rapidly than the members, 3,867 as against 1,025 in 1837. One of the outstanding exhibits of the year (according to the report submitted to the annual general meeting on April 29) was a group of young Hainan gibbons, but the first giant forest hogs to reach any zoological garden and several white-tailed gnus, a species now extinct in a wild state, will arouse equal interest when they are shown to the public. The only important building erected during the year was the Studio of Animal Art, opened on April 21 by Lord Snell; but an innovation which obviously met a popular need was the launching of the *Zoo* magazine, the circulation of which has been maintained at close upon 100,000 copies.

Dr. Marie Stopes's Coronation Ode

IN his broadcast speech on Coronation Day, May 12, H.M. King George referred to the Royal office to which he has succeeded as the symbol of the constitutional link of Empire and to the service which he desired to render while occupying it. Dr. Marie Stopes has been inspired by the occasion to compose a lyrical poem in which she happily expresses these and other attributes of kingship as represented by his present Majesty. Four lines may be appropriately quoted here: they are:

Thou art the centre of a world-wide plan
To make new triumph out of world-worn things.
Thou art the symbol of a nation's pride,
The dazzling spear-point of an Empire's van.

The ode has been attractively printed upon a card, and copies may be obtained from The Eclipse Press, 108 Whitfield Street, London, W.1, at the price of 1*d*. each or twenty for 1*s*.

Jubilee Number of *The Observatory*

THE inception sixty years ago of a monthly magazine, *The Observatory*, familiar in its blue covers to astronomers the world over, is commemorated in a special number, No. 755, of April 1937. The magazine was founded in 1875 by Sir William Christie, who was then Astronomer Royal, and it has been carried on voluntarily ever since, without any monetary grants whatsoever towards its publication, by successive editors, mainly from the observatory staffs at Greenwich and at Cambridge. The present number includes three special articles. In the first, Sir Frank Dyson reviews "Sixty Years of Meridian Astronomy"; the second article is by Sir Arthur Eddington (himself one of the joint editors in 1913–19) who writes on "Interstellar Matter"; while the third is from a veteran contributor (editor, 1893–1912), Mr. H. P. Hollis, whose article deals with Airy's water telescope. A unique feature of the past which found an appreciative circle of readers was the monthly anonymous contributions "From An Oxford Notebook" by the late Prof. H. H. Turner; these notes ran without a break from 1894 until Turner's death in 1930. The current numbers of *The Observatory* carry on the useful work of providing a report of the discussions at the meetings of the Royal Astronomical Society (including Geophysical Discussions), in publishing articles by astronomers of international repute, and in airing views in the pages devoted to correspondence.

Inland Water Survey

CAPT. W. N. MCCLEAN is publishing, in graphical form on standard sheets, the continuous record of water-levels, flows and storages, and of rainfall and temperature, for the Rivers Garry, Moriston and Ness, the three principal rivers of the Ness Basin of 700 square miles area. The records cover the period September 1929 to the end of the year 1935, and are obtainable in separate sheets or as a complete series for each river in a portfolio. The river survey work has been organized and carried out by the staff of River Flow Records, under the direction of

Capt. W. N. McClean. Capt. McClean's activity in the development of inland water survey in Great Britain is well known, and, in addition to the practical survey and record work, he initiated and organized the discussion on the need for this survey which the British Association staged at the York meeting in 1932. That discussion gave birth to the committees of the British Association and Institution of Civil Engineers, and these two bodies induced the Government to appoint the present Inland Water Survey Committee of the Ministry of Health. The graphical records of the Ness Basin rivers, which are similar to those published for the Aberdeenshire Dee, are the first of their type in Great Britain, and bring together the hydrological and meteorological records in a form from which statistical data may be derived or any desired analysis of river flow and storage may be made. A list of the published records can be obtained from "River Flow Records", Parliament Mansions, Victoria Street, S.W.1.

American Society of Ichthyologists and Herpetologists

AT the twentieth annual meeting of the American Society of Ichthyologists and Herpetologists, held in Washington, D.C., on May 4–8, the following officers were elected: *Honorary Presidents*, John T. Nichols and Dr. Leonhard Stejneger; *President*, Prof. William K. Gregory; *Vice-Presidents*, L. M. Klauber, Leonard P. Schultz, and Dr. Hobart M. Smith; *Secretary*, M. Graham Netting; *Treasurer*, Dr. Arthur W. Henn; *Editor-in-Chief*, Mrs. Helen T. Gaige, of *Copeia*; *Ichthyological Editor*, Lionel A. Walford; *Herpetological Editor*, Karl P. Schmidt. The election of four honorary foreign members was announced at the meeting; namely, for 1936, Prof. David M. S. Watson, University College, London, and Prof. Franz Werner, University of Vienna; for 1937, Dr. Leo S. Berg, Academy of Sciences, Leningrad and Dr. W. Wolterstorff, Museum fur Natur- und Heimatkunde, Magdeburg. Dr. G. A. Boulenger is the only previously elected honorary foreign member.

Systematics in Relation to General Biology

WHILE taxonomy has, in the past, been based mainly on morphology, the advances of the past two decades in cytology, ecology, genetics and other branches of biology have made it necessary to consider their contribution to the subject. As a result of meetings of members of the staffs of the John Innes Horticultural Institution and the Royal Botanic Gardens, Kew, and of zoologists interested in taxonomy, a "Committee on Systematics in Relation to General Biology" has been formed, the first open meeting of which will be held in the rooms of the Linnean Society, Burlington House, London, W.1, on June 25 at 3 p.m. All biologists interested in the general aims of the Committee are invited to attend. The chairman of the Committee is Dr. Julian S. Huxley, and the two secretaries are Mr. J. S. L. Gilmour, Royal Botanic Gardens, Kew (botany), and Mr. H. W. Parker, British Museum (Natural History), South Kensington, S.W.7 (zoology).

U.S. National Academy: New Members

THE following have recently been elected members of the U.S. National Academy of Sciences: Dr. C. B. Bridges, geneticist at the California Institute of Technology; Dr. O. E. Buckley, assistant director of research in the Bell Telephone Laboratories; Prof. A. J. Dempster, professor of physics in the University of Chicago; Prof. E. W. Goodpasture, professor of pathology in Vanderbilt University; Dr. C. G. Hartman, research associate in the Department of Embryology, Carnegie Institution of Washington: Dr. D. F. Hewett, U.S. Geological Survey; Prof. Leo Loeb, professor of comparative pathology in Washington University (St. Louis); Dr. D. A. MacInnes, associate member (physical chemistry) in the Rockefeller Institute for Medical Research; Dr. G. R. Minot, Boston City Hospital; Prof. J. von Neumann, professor of mathematical physics in the Institute for Advanced Study, Princeton; Dr. S. B. Nicholson, astronomer at Mt. Wilson Observatory; Prof. Otto Struve, director of Yerkes Observatory; Dr. F. B. Sumner, professor of biology in the Scripps Institution of Oceanography; Dr. Charles Thom, soil microbiologist in the U.S. Department of Agriculture, and Prof. E. C. Tolman, professor of psychology in the University of California. Prof. August Krogh, of the University of Copenhagen, known for his work in animal physiology, has been elected as a foreign associate of the Academy.

Announcements

DR. W. L. BURGESS, Dr. W. R. Wooldridge, Sir Louis J. Kershaw and Sir Joseph Barcroft have been appointed members of the committee set up in November 1936 to review the facilities available for veterinary education in Great Britain (see NATURE, 138, 837; 1936). Dr. Thomas Loveday, vice-chancellor of the University of Bristol, has been appointed chairman.

PROF. JAMES YOUNG, director of the Department of Obstetrics and Gynæcology at the British Post-Graduate School, has been elected chairman of the Medical Advisory Board of the British Social Hygiene Council in succession to Sir Farquhar Buzzard.

PROF. WLADIMIR KOPPEN, the eminent Graz meteorologist, has been awarded the shield of nobility by the German Chancellor.

DR. RICHARD HESS, professor of zoology at the University of Berlin, has been made an honorary member of the Bavarian Academy of Sciences.

THE British Homœopathic Congress will be held at the Langham Hotel, London, W.1. on June 17–18. Further information can be obtained from the Secretary, 69 Elizabeth Street, S.W.1.

THE Fourth General Assembly of the International Union for the Scientific Investigation of Population Problems will meet in Paris on July 28 in connexion with the International Population Congress, organized by the French National Committee, which takes place on July 29–August 1.

Letters to the Editor

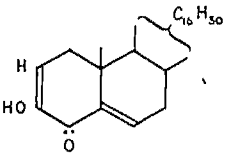
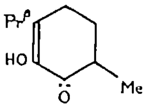
Cholesterol and the Adrenal Cortical Hormone

THE discovery that carbon atom C_4 of the cholesterol molecule is the first point of attack by oxygen, leading to the formation of *cis* $\Delta^{5,6}$-cholestene-3 : 4-diol, suggested that this reactive primary oxidation product may play an important role in the metabolism of cholesterol and the sexual hormones. Experimental confirmation of this view was obtained by feeding experiments, which showed that the diol, as well as its intermediate dehydration product cholestenone, were converted into coprosterol by the animal organism[1]. We have now obtained by mild oxidation of the 3-monoacetate (or 3-benzoate) of the *cis*-diol what is probably the oxide of 4-ketocholestenol 3-acetate (or 3-benzoate). These compounds yield on hydrolysis a highly reactive substance $C_{27}H_{42}O_2$ (I) which possesses the typical grouping —C=COH—CO— of diosphenol (buchu-camphor) (II).



I



II

As the substance, like diosphenol, functions in several tautomeric forms, it would be arbitrary to assign a definite structural designation to it, and we propose to call it *diosterol* (abbreviated from diossterol). Diosterol reduces ammoniacal silver solution, reacts with Schiff's fuchsin reagent and, as a phenol, is extracted by strong alkali from its ether- or benzene solution, forming yellow insoluble sodium or potassium salts (see forthcoming publication in conjunction with W. W. Starling and V. A. Petrow). The intensity of the ultra-violet absorption spectrum of diosterol is $\epsilon_M = 22,000$ at 320 mμ, that is, twice that of diosphenol at 270 mμ [2]. Diosterol was found to be identical with the "substance $C_{27}H_{42}O_2$" of Inhoffen[3] and Butenandt and Schramm[4], which is obtainable by a complex debromination process from certain bromination products of cholestenone.

Since it has now been shown that the same substance arises from cholesterol in definite stages by a process which may easily be visualized as a biological oxidation occurring in the animal organism, a hint is afforded in explanation of the unknown position and function of the fourth oxygen atom in the adrenal cortical hormone. This labile hormone, essential for life, possesses the remarkable property for a steroid of reducing ammoniacal silver solution, usually attributed to the terminal —CO.CH$_2$OH group in ring IV.

It is tempting to suggest that the diol and its immediate oxidation products may be steps in the biological formation from cholesterol of the labile cortical hormone of the adrenals. A new experimental approach to the system from the sexual hormones and other steroids has become available by the further discovery that the conversion of cholesterol into *cis*-cholestene-3 : 4-diol can be effected by simple treatment of cholesterol dibromide with silver acetate in pyridine at room temperature. This reaction, which is probably a general one, is at present being applied to steroids with a 5 : 6 ethylenic linkage.

Inhibition of the Gonadotropic Activity of Pregnancy Urine Extract by the Serum of Rabbits injected with an Extract of Male Urine

THE fact, first noted by Bachmann, Collip and Selye[1], that the serum of an animal which has received prolonged treatment with gonadotropic substances may acquire antigonadotropic properties, has been confirmed by many other workers. Twombly[2] was able to produce active antisera by the use of solutions of pregnancy urine extract, most of the initial gonadotropic activity of which had been lost during storage, and his results suggested that the presence of active gonadotropic substance, in the material used for repeated injection, might not be essential. We were able to confirm this supposition.

A precipitate was prepared from the urine of normal male factory workers, by a method known to be suitable for concentration of the gonadotropic substances in pregnancy urine. 3·9 mgm. of this preparation (representing 50 c.c. original urine) yielded no trace of a gonadotropic reaction in immature female rats ; 22·5 mgm. (representing 300 c.c. original urine) produced œstrus in six treated rats, with luteinization in one of them.

An adult female rabbit received 10·0 mgm. daily for 30 days (representing 130 c.c. original urine daily). The ovaries were apparently not influenced by this treatment, for autopsy showed ripe follicles only. Each of six immature female rats then received a total dose of 1·2 c.c. of the blood serum of this rabbit at the same time as 5 units of gonadotropic hormone from pregnancy urine (Pregnyl Organon). The serum was injected on the left, the Pregnyl on the right side of the rat, the number and interval of the injections being the same as in pregnancy tests according to Aschheim and Zondek. Œstrus, enlargement of the uterus and luteinization were completely inhibited by the addition of the rabbit serum, occurring only in the controls. Each of six immature male rats then received 12 R.U. of Pregnyl and 3 c.c. serum during six days. Addition of the serum to the gonadotropic preparations here inhibited the enlargement of seminal vesicles, preputial glands and testes produced in controls which had the same dose of hormone without serum.

Our experiments prove that it is possible to obtain rabbit serum with antigonadotropic properties by repeated injection of a negligibly gonadotropic extract of male urine. It is just possible that the effect is due to the traces of the gonadotropic hormone; more likely, in view of the experience of Twombly, it is due to the presence of a different substance with similar antigenic properties.

Rabbits treated with serum from a non-pregnant mare failed to produce a serum that would inhibit the gonadotropic activity of pregnant mare serum in immature female rats.

Coupled Oxidation of Ascorbic Acid and Hæmochromogens

Hæmochromogens catalyse the oxidation of ascorbic acid at a pH below 7 at which there is no autoxidation of ascorbic acid. We can confirm this result of Barron and co-workers[1], but the authors have overlooked that the hæmochromogens also undergo oxidation under these conditions, as first observed by Karrer and co-workers[2]. The product of this oxidation is verdohæmochromogen, a bile pigment iron compound[3].

We have studied in detail the coupled oxidation of ascorbic acid and pyridine hæmochromogen, with the double purpose of investigating whether or not the physiological hæmoglobin breakdown and the bile pigment formation can be assumed to proceed in this way and of getting information on the mechanism of hæmin catalysis.

Hæmin was measured spectro-colorimetrically as hæmochromogen after reduction with hyposulphite, ascorbic acid iodometrically or with the indicator method in the hydrogen cyanide trichloroacetic acid filtrate. In air, with a 2 mM. vitamin and a 0·2 mM. hæmin concentration, half the hæmochromogen is transformed into verdohæmochromogen during 1 minute at 37°, and after 10 minutes this oxidation is complete. The catalytic effect of pyridine-hæmochromogen, studied by Barron and co-workers over periods of hours, was thus largely due to verdohæmochromogen. The oxidation of 1 mgm. of vitamin is accompanied by that of 0·2-0·3 mgm. hæmin, rather independently of the hæmin and vitamin concentrations; at lower oxygen pressure relatively more hæmin is oxidized. The oxidation of vitamin leads to dehydroascorbic acid. Glutathione does not inhibit verdohæmochromogen formation in presence of ascorbic acid, but protects ascorbic acid by back reduction of dehydroascorbic acid; with glutathione alone, not verdohæmochromogen, but a hæmatin compound of hæmatin *a*-type is obtained. In the system oxygen—hæmochromogen—ascorbic acid—glutathione—glucose dehydrogenase—glucose, the oxidation of a hæmatin to a bile pigment is coupled with the final oxidation of glucose alone.

The mechanism of the coupled oxidation is interesting. Peroxides do not produce a verdohæm compound with hæmatin in pyridine, or if acting on pyridine hæmochromogen in the absence of atmospheric oxygen. Catalase, however, inhibits the oxidation of hæmin, though not of vitamin. Incubating hæmin in dilute pyridine with ascorbic acid and a small amount of hydrogen peroxide in nitrogen, the formation of a brown-green compound with an absorption band at 639 mμ is observed; by its properties it can be clearly distinguished from acid hæmatin and from hæmochromogens possessing a similar absorption band. It is retransformed to hæmochromogen by hyposulphite, by catalase and more slowly by ascorbic acid alone, and is oxidized to ferric hæmochromogen (parahæmatin) by ferricyanide or by an excess of hydrogen peroxide. We conclude from these observations that the substance is a ferrous hæm-hydrogen peroxide compound containing pyridine and perhaps also ascorbic acid. In nitrogen it is relatively stable in presence of an excess of ascorbic acid, but on admittance of air it is rapidly oxidized to verdohæmochromogen. For the oxidative splitting of the porphyrin ring to the bile pigment chain the action of oxygen on the hæm-hydrogen peroxide compound (combined action of oxygen and hydrogen peroxide) appears to be necessary.

The absorption band at 639 mμ is also observed during the initial stages of the coupled oxidation of hæmochromogen and vitamin by atmospheric oxygen. Here the hæm-hydrogen peroxide compound may arise by the transfer of hydrogen (Wieland) from ascorbic acid to a hæmochromogen peroxide (Warburg) formed initially by the action of oxygen on hæmochromogen; or hydrogen peroxide may be formed first in a radical chain mechanism[4] and then combine with hæmochromogen. The formation of the hæm-hydrogen peroxide compound from hæmochromogen, oxygen and ascorbic acid, and its reaction with hydrogen peroxide and ascorbic acid (peroxidase action of the hæmochromogen) constitute a catalytic cycle in which hæmochromogen acts as oxidase on ascorbic acid.

At the moment we are not yet certain how great a part of the vitamin oxidation proceeds in this way. Ferric hæmochromogen oxidizes ascorbic acid and ferrous hæmochromogen is re-oxidized by molecular oxygen. 10^{-3} mol cyanide inhibits very little, but ascorbic acid can reduce cyanhæmatin in pyridine. We have, however, additional evidence that the vitamin oxidation cannot be explained on this basis alone. If vitamin were to act in the reduction process only, we should find a greater percentage of the hæmatin in the form of hæmochromogen, when a higher vitamin concentration is applied; the contrary is true. For this reason, it must be assumed that ascorbic acid catalyses the oxidation of ferrous hæm, which is to be expected from the reaction mechanism described above. Again, vitamin may be oxidized and ferric hæmochromogen (in addition to verdohæmochromogen) arise in the reaction of the hæm-hydrogen peroxide compound with oxygen.

The absorption spectrum of the new hæm-hydrogen peroxide compound differs totally from that of the methæmoglobin-hydrogen peroxide compound[4] and from the catalase-hydrogen peroxide compounds[6] of Keilin and Hartree. In its properties it seems more closely related to the former.

An absorption band at 639 mμ has been observed by Warburg and co-workers[7] when *B. pasteurianum* was exposed to air in presence of cyanide. There is reason to assume that it is due to the same substance. Cyanide inhibits catalase and causes the accumulation of hydrogen peroxide in the cell, thus producing conditions under which the substance is formed from protohæmochromogen. Quite different are the substances with a band at 628 mμ, occurring as cytochrome a_2 in several bacteria; they are probably biliviolin-hæmochromogens[8].

Visual Purple System in Fresh-water Fishes

THE visual purple of mammals, birds, amphibians, and certain marine fishes [1,2] absorbs light maximally at 500 mμ and participates with retinene and vitamin A in a retinal cycle[3,4]. I shall refer to this substance specifically as *rhodopsin*[5]. The visual purple of freshwater fishes possesses different spectral properties[1]; I shall refer to it as *porphyropsin*.

I have examined the porphyropsin system in white perch (*Morone americana*), yellow perch (*Perca flavescens*) and pickerel (*Esox reticulatus*).

Isolated dark-adapted retinas from these fishes are purple in colour. Exposed to bright light they turn russet, then fade slowly to very pale yellow. The fading from russet to yellow occupies about ¾ hour at 25° C. and possesses a high temperature coefficient. Russet retinas, replaced in darkness, regenerate porphyropsin, though always markedly less than is present in the dark-adapted retina. The light process is therefore reversible. Completely faded retinas do not re-form porphyropsin; isolation of the retina from the eye abolishes this reaction.

The nature of these changes is revealed further in the following experiment. Right and left retinas of six dark-adapted white perch were prepared separately. One set was extracted by shaking with benzine in the dark, then was bleached in bright light and immediately re-extracted. The second set was bleached and allowed to fade completely before extraction. The three benzine extracts were brought into carbon disulphide and their spectra measured. They were concentrated in chloroform, and spectra of the blue products obtained on mixing with antimony trichloride were examined. The results are summarized in the following table:

Retinal condition	Colour	Benzine extract in CS_2	Antimony chloride reaction
(*A*) Dark-adapted	Purple	Faintest yellow: simple end-absorption in violet	Very small band at 696 mμ
(*B*) Bleached	Russet	Deep orange-yellow. end-absorption with inflection (band ?) at about 400 mμ	High band at 703 mμ
(*C*) Bleached and faded	Faint yellow	Light yellow: simple end-absorption	High band at 696 mμ; broad flat hump at 640 mμ

No trace of either vitamin A or retinene was found in these tissues (compare Wald[3]). The orange-coloured 703 mμ chromogen, liberated from porphyropsin by light (*B*), is transformed by the facing process into the yellow 696 mμ chromogen (*C*), a small quantity of which (about 1/5) is present also in the dark-adapted retina (*A*).

Solutions of porphyropsin from the three species examined possess identical properties. Spectra of a neutral preparation from white perch in 2 per cent aqueous digitonin, measured against an equal depth of distilled water, are shown in Fig. 1. Curve *g* is the spectrum of the solvent alone.

Porphyropsin in solution possesses a broad absorption band maximal at 522–525 mμ (curve *a*). The secondary rise in absorption following a minimum at 430–440 mμ has appeared consistently, but may be due to impurities. The preparation was exposed to bright light (about 700 ft. candles) for ½ minute. It was then left in complete darkness and its spectrum measured periodically, curve *b* at 1·2 min., *c* at 4·6 min., *d* at 12·5 min., and *e* at 64·5 min. from the onset of the irradiation. The initial orange-coloured photo-product (curve *b*) slowly turned to yellow, the extinction falling in the region of 520 mμ and simultaneously rising below 444 mμ. Dark processes in this instance account for 34 per cent of the total fall in extinction at 520 mμ.

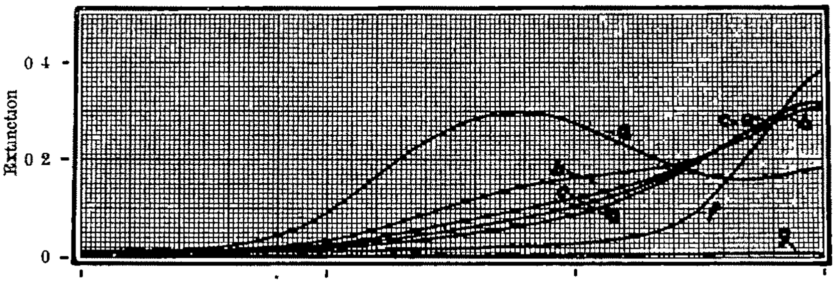

Fig. 1.

The final yellow product (curve *e*) changes colour reversibly with *p*H, tending toward orange in acid and pale yellow in alkaline solution. The present residue, brought to *p*H 11, yielded curve *f*.

This final bleached product yields all its colour on shaking with benzine containing 1 per cent ethanol. The benzine extract, brought back into neutral aqueous digitonin solution, possesses a spectrum-like curve *e*. It changes in colour with *p*H, as does the whole bleached residue. It appears to be the same pigment as is extracted from bleached (russet) retinas (extract *B* in the table above).

If curve *e* is subtracted from *a*, a function roughly symmetrical about a maximum at 540 mμ is obtained, similar to that observed by Kottgen and Abelsdorff[1]. Below 455 mμ this function assumes negative values. Obviously it does not, as commonly supposed, represent the spectrum of porphyropsin itself.

In every detail so far examined, the porphyropsin system faithfully reproduces the behaviour of the rhodopsin system, but with quite different components. It appears to consist in a retinal cycle of the form: porphyropsin $\underset{(1)}{\overset{\text{light}}{\rightleftarrows}}$ russet pigment (703 mμ chromogen + . . .) $\underset{(2)}{\rightarrow}$ yellow pigment (696 mμ chromogen + ...) $\underset{(3)}{\rightarrow}$ porphyropsin. Isolation of the retina from the eye cuts the cycle at (3); extraction of porphyropsin from the retina eliminates in addition reactions (1) and (2).

It is curious that the possession of porphyropsin divides all freshwater fishes so far examined—eleven species in all—even from certain very closely related marine forms[3,5]. The division may not be absolute, for recently a number of marine fish visual purples have been reported to possess intermediate properties[6]. These are possibly mixtures of rhodopsin and porphyropsin. The coincidence in a single retina of a number of visual systems accurately parallel in behaviour but differing in spectral properties should serve as an appropriate basis for colour vision.

Thermal Decomposition of Ethylene Oxide

IN a series of papers communicated to the Faraday Society, an attempt has been made to prove that the thermal decomposition of a number of simple organic compounds may be accounted for on the assumption of the following mechanism.

The compound *A* first undergoes change in accordance with an equation,

$$A = B\ (+\ C). \qquad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

This process, which is called the *background reaction*, is readily reversible when *A* and *B* represent ethane and ethylene, propane and propylene, and probably acetaldehyde and vinyl alcohol, but in the case which we are considering it is sensibly irreversible.

The main reaction, following on the background reaction, is represented by the equation,

$$A + B = AB = (AB) = C + D, \text{ etc.} \qquad . \quad (2)$$

where *AB* and (*AB*) represent the activated complex, and what has been termed an *unstable intermediate*. The latter may decompose, or even react with some other substance such as hydrogen, to form one or more products, but it is the rate of formation of the unstable intermediate which we measure.

Further study of the thermal decomposition of ethylene oxide furnishes confirmation of this theory. This compound decomposes in the neighbourhood of 400° according to the equation,

$$(CH_2)_2O = CH_4 + CO. \qquad . \quad . \quad . \quad . \quad (3)$$

A little acetaldehyde is formed at the same time, and it has been suggested that this compound is an intermediate between ethylene oxide and the final products. However, it seemed likely, according to the theory referred to above, that the reaction,

$$(CH_2)_2O = CH_3CHO, \qquad . \quad . \quad . \quad . \quad (4)$$

might really be the background reaction for the decomposition of ethylene oxide, in which case the main reaction would be initiated by the collision of molecules of ethylene oxide and acetaldehyde, represented by,

$$(CH_2)_2O + CH_3CHO = [(CH_2)_2O, CH_3CHO] = 2CH_4 + 2CO. \qquad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

To test this theory, quantities of ethylene oxide and acetaldehyde were heated separately in a silica tube for 30 minutes at 400°. In a third experiment the same quantities of ethylene oxide and acetaldehyde was heated similarly, mixed together. As was anticipated, the quantity of carbon monoxide and methane obtained from the mixture was about ten times the sum of the quantities obtained in the experiments in which the two compounds were heated separately.

So far, it is only in the case of the hydrocarbons that it has been possible to eliminate the effect of the background reaction, and to study the main reaction by itself. However, by experimenting at temperatures at which ethylene oxide and acetaldehyde alone decompose very slowly, it is found to be possible to study in detail the process represented by equation (5).

This hypothesis enables us to dispense with the conception of the unimolecular reaction, and also of that of free radicals, in order to account for the thermal decomposition of simple organic compounds. The processes are accounted for on the supposition that the reactions involve simple bimolecular processes.

Inhibitions of Organic Decompositions by Nitric Oxide

STAVELEY and Hinshelwood have recently shown that the thermal homogeneous decompositions of certain substances such as ethers and aldehydes are to a greater or less extent inhibited by small amounts of nitric oxide, and they have used this as a means of establishing the extent to which these reactions proceed via a mechanism of reaction chains[1]. With dimethyl ether the effect is most marked, and in this case, when the decomposition is about half completed, the reaction velocity rises fairly abruptly to its 'normal' value.

We have attempted to discover the fate of the nitric oxide by photographing the absorption spectrum of the gaseous reaction mixture at intervals during the course of a run. About ten photographs were usually taken, with exposures of some seconds each, in a run of about thirty minutes in all. The spectrograph was a small quartz - fluorite instrument with dispersion 2000–7000 A. and the source was a hydrogen discharge.

With dimethyl ether at the beginning of the run, only the doublet nitric oxide bands at 2265 and 2151 A. were observed. As the reaction proceeds, these bands gradually weaken, and are replaced with increasing intensity by the strongest bands of ammonia at 2210, 2166, 2127, etc. . . . The stage of the reaction at which the nitric oxide disappears agrees entirely with that expected from the kinetic measurements. This seems to indicate that whatever the primary stage in the interaction of radicals with the nitric oxide may be, a final product, which does not affect the rate of the reaction, is ammonia. The process

$$NO + CH_3 \rightarrow CO + NH_3$$

would be expected to be exothermic, but we regard this process (occurring in one stage) as unlikely. Other experiments shortly to be described suggest that formaldoxime may be an intermediate product, while the condensation from the reaction mixture by liquid air of a blue product may indicate an unstable nitroso compound.

When the above experiment is repeated using diethyl ether, the nitric oxide bands are gradually replaced as the run proceeds by a continuous absorption which extends towards 2300 A. from shorter wave-lengths, and there are indications of a few feeble diffuse bands in the region of 2350 A. This result might well arise from the presence of methylamine, formed by the process :

$$C_2H_6 + NO \rightarrow (X) \rightarrow CH_3NH_2 + CO$$

The experiments are being extended to other cases such as the decomposition of alkylene oxides.

Photochemical Reduction of Ceric Ions by Water

IT has been shown previously that in the absorption of ultra-violet light by several ions in aqueous solution, the photochemical primary process consists in a transfer of an electron from the ion to a water molecule, with a consequent evolution of gaseous hydrogen. This was shown to occur both with negative ions[1] and positive ions[2].

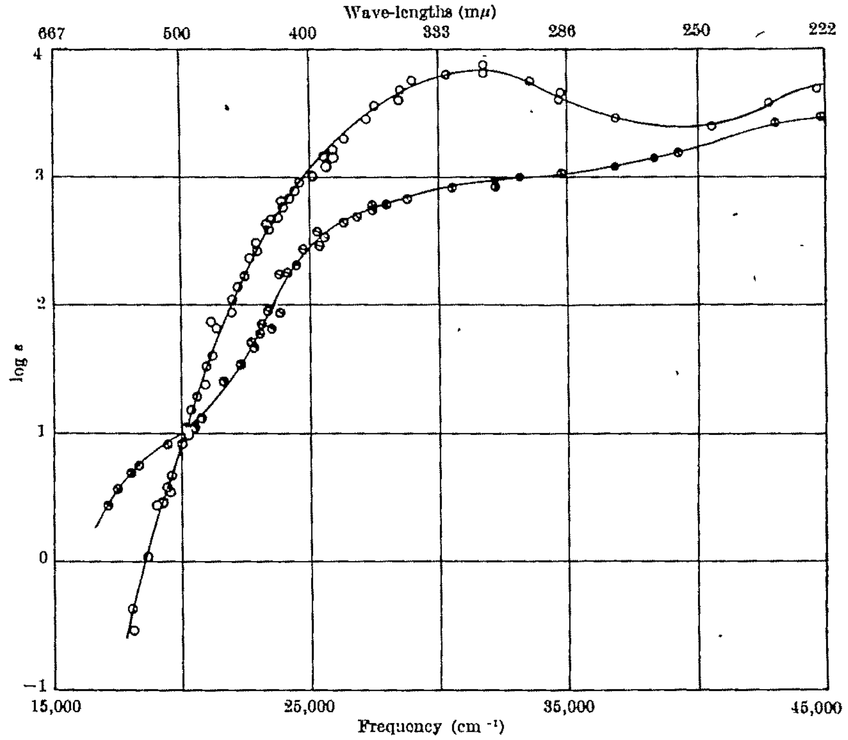

Fig. 1.

MOLECULAR EXTINCTION COEFFICIENTS OF CERIC PERCHLORATE (⌀) AND CERIC SULPHATE (O).

Some form of inverse process has been shown to occur in the elementary process of the quenching of fluorescence of dyes and in the photo-reduction of dyes in solution[3]. By exciting the dye molecule an electron goes into a higher level, leaving an empty electronic level behind into which an electron from a neighbouring molecule may be taken up. In this process the electron affinity of the excited molecule is increased by the amount of its excitation energy.

Our experiments have shown that a similar photochemical process can take place between ceric ions and water. By irradiating an aqueous solution of ceric perchlorate with the ultra-violet light of a strong mercury arc (described previously[2]) we found a considerable evolution of a gas which was shown to be pure oxygen. For example, in one of our experiments, which was carried out with a solution containing 0·1 mol ceric perchlorate (complete absorption) and about 1 mol perchloric acid per litre, 2 c.c. of oxygen (N.T.P.) were evolved per litre per minute at the beginning. The speed of the reaction decreases while the reaction is going on. This was found to be due to the formation of cerous ions, this view being confirmed by experiments where cerous salt was added directly. Cerous ions also appear in the presence of traces of organic substances in the solution which are easily oxidized by ceric ions.

The rate of the reaction remains unchanged by filtering the light through 20 per cent perchloric acid solution. The perchlorate ion, in fact, is practically non-absorbing in the near ultra-violet and is also not decomposed to any appreciable extent under the conditions in question. We did not observe the reaction on irradiating a solution of ceric sulphate (in sulphuric acid solution). This must be attributed to the fact that ceric sulphate solutions contain practically no free ceric ions[4] (which are present in the perchlorate solution) and are responsible for the reaction observed. This is also indicated by the difference in the absorption spectra, which we have determined (Fig. 1).

The following mechanism is proposed for the observed reaction:

(1) light absorption:

$$Ce^{4+} + h\nu = Ce^{4+*} \text{ (excited ion).}$$

(2) decomposition of water:

$$Ce^{4+*} + H_2O = Ce^{3+} + H^+ + OH.$$

(3) oxygen formation:

$$2OH = H_2O + O,\ 2O = O_2; \quad \text{or}$$

(4) reverse process.: $Ce^{3+} + OH = Ce^{4+} + OH^-$.

It is possible that hydrogen peroxide is formed as an intermediate product which is then decomposed by the ions or by light. Reaction (4) is responsible for the influence of cerous ions and also for the low quantum efficiency, which was found to be of the order of 0·1 in solutions containing practically no cerous ions at the beginning.

In conclusion, we should like to express our sincere thanks to Prof. F. G. Donnan for his continuous help and encouragement.

Polarographic Investigations in Serological Cancer Diagnosis

IT has been mentioned in these columns[1] that the polarographic 'wave' produced on the current-voltage curve by sulphydryl or disulphidic groups of serum proteins can be used to distinguish between normal and carcinomatic serum. In the case of cancer the height of this characteristic protein 'wave' is always found a little lower than that in the normal serum However, when the sera are treated with alkali hydroxide, the height of the protein 'wave' increases in the carcinomatic serum less than in the normal serum. Thus the differences between them are considerably increased. This circumstance has to be ascribed to the liberation of sulphydryl or disulphidic groups of serum proteins as the result of their alkaline denaturation. (Cf. Mirsky and Anson[2].)

The same increase of the height of the protein 'wave', leading to a similar difference between carcinomatic and normal serum, can be obtained when the proteins are denatured with diluted hydrochloric acid (c. 0·05 N). The denaturation under these conditions proceeds at room temperature very slowly, but can be hastened at a higher temperature (c. 40° C.).

A polarographic study of the kinetics of the peptic cleavage of native and coagulated proteins has revealed an increase of the protein 'wave'. This effect has now been applied to show the differences between the protein 'wave' of carcinomatic and normal serum, since they should be largest when the active sulphydryl or disulphidic groups are liberated. For that purpose, to 5 c.c. of 0·05 N hydrochloric acid containing 5 mgm. of pepsin, 0·2 c.c. of serum was added, the temperature being maintained at 40° C. After 5, 10, 15, 30 minutes the solution was withdrawn by 0·2 c.c. and added to 10 c.c. of $1{\cdot}6 \times 10^{-3}$ N cobalt chloride in 0·1 N ammonium chloride in 0·1 N ammonia. The polarographic curve due to this solution showed the expected increase of the protein 'wave'. Thus this method of procedure leads to a quick differentiation—in about 15 min.—between carcinomatic and normal serum. From the material examined polarographically up until now (more than 250 different samples), the height of denatured protein 'wave' in carcinomatic cases is smaller by 3–50 per cent than the height of that from normal serum. The decrease depends on the stage of development of cancer. It must be remembered, however, that some acute cases of inflammation and fever yield a serum reaction similar to that of cancer.

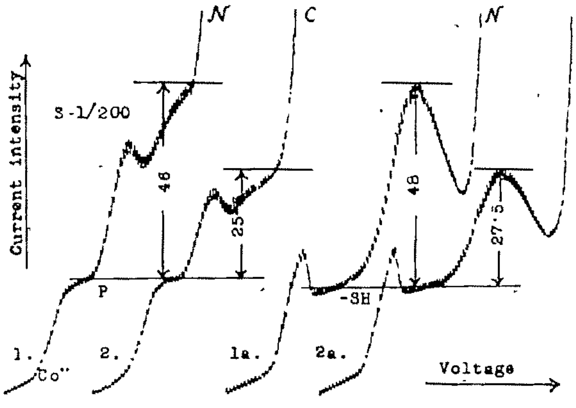

Fig. 1.

CURVE 1, NORMAL SERUM, 'WAVE' P = 46 MM. CURVE 2, CARCINOMATIC SERUM (CANCER UTERI), 'WAVE' P = 25·5 MM. BOTH SERA WERE TREATED WITH PEPSIN AS INDICATED, DILUTION OF SERUM = 1 : 1,250.

CURVE 1a, HYDROLYSATE OF NORMAL SERUM, CYSTINE 'WAVE' = 48 MM. CURVE 2a, HYDROLYSATE OF CARCINOMATIC SERUM, CYSTINE 'WAVE' = 27·5 MM.; DILUTION OF SERUM = 1 : 2,000.

From these experimental facts two questions arise: namely, what is the origin of the difference between carcinomatic and normal serum, and whether disulphidic or sulphydryl or both groups are responsible for the polarographic effect of proteins?

To solve these problems the sera were completely hydrolysed with 5 N hydrochloric acid (1 c.c. of serum boiled with 20 c.c. of 5 N hydrochloric acid for 8 hours and made up to 100 c.c. with water) and the hydrolysates were submitted to polarographic analysis for cystine by my method[3]. In the hydrolysate of the carcinomatic serum there was always found less cystine than in the normal one. The ratio of the cystine concentration agrees with the ratio of the polarographic 'waves' of the denatured or proteolysed serum proteins (see Fig. 1).

These results were controlled by a colorimetric estimation of cystine in the hydrolysates using the Folin-Looney uric acid reagent as modified by Mirsky and Anson[4]. Thus in carcinomatic serum the content of the protein cystine was found to be smaller than in the normal serum.

As to the question whether the group responsible for the polarographic reaction is —S—S— or —SH, polarographic as well as colorimetric tests show that the sulphydryl groups are not present in an appreciable amount, so that the effect must be mainly due to the disulphidic groups.

Details of this research will soon be published elsewhere.

Sign of the Magnetic Moment of Free Neutrons

USING a method recently described by us[1], we have now succeeded in determining the sign of the magnetic moment of free neutrons.

The method is based on the fact that the direction of precession of particles in a magnetic field depends on the relative direction of spin and magnetic moment (this is the meaning of the term "sign of the magnetic moment"). The direction of precession can be observed by using bars of magnetized iron as polarizer and analyser[2], which are placed at an angle relative to each other[1, 3].

The experimental arrangement was essentially the same as before[1] except that one of the iron rings was rotated through an angle of 90° with respect to the other, with the neutron beam as axis, making the polarizing and analysing fields perpendicular to each other and to the neutron beam.

A short solenoid was placed between polarizer and analyser, coaxial with the neutron beam. The field in the solenoid (which was found to be fairly homogeneous, on account of the iron below and above) was adjusted so that the neutrons should rotate by 90°, on the average, on passing through the coil. (For calculating this field the magnetic moment of the neutrons was assumed to be 2 N.M.). The neutrons leaving the polarizer in the 'parallel' position arrived at the analyser in the 'parallel' or 'antiparallel' position, depending on the direction of precession, with correspondingly different probabilities of getting through.

The current in the solenoid was reversed at short intervals, and 480,000 counts in all were taken. An unambiguous difference of $(1 \cdot 10 \pm 0 \cdot 29)$ per cent of the total intensity (of which about 50 per cent was due to thermal neutrons) was found on reversing the current. The magnitude of the difference was of the order expected, which shows that the field in the solenoid was correctly chosen.

From the sign of the difference we conclude that the magnetic moment of the free neutron is negative that is, the relative direction of spin and magnetic moment is the same as in the electron. This agrees with expectations based on the magnetic moments of proton and deuteron.

[1] NATURE, 139, 756 (1937).

[2] Bloch, F., *Phys. Rev.*, 50, 259 (1936).

[3] A somewhat similar method has been proposed by I. I. Rabi, *Phys. Rev.*, 51, 652 (1937). It may be well to point out that the classical concept of precession gives the same result, in our case, as the quantum mechanical calculation

Experimental Test of the Proton-Neutron Exchange Interaction

IT has already been pointed out[1] that, when a proton or neutron of relativistic velocities traverses matter, it travels until it makes a head-on collision with a neutron or proton respectively in the material, transferring nearly its whole energy to this particle, which then travels forward in very nearly the same direction. This process is repeated again, the latter particle transferring nearly its whole energy to a proton if it be a neutron, and vice versa. Let q denote the effective cross-section for either of these processes. We thus get a chain, the proton giving place to a neutron, which then gives place to a proton and so on. This effect is characteristic of an exchange interaction between a proton and a neutron, and would not occur with a non-exchange interaction. As it is important to know the form the proton-neutron interaction takes in the relativistic case, we wish to point out in this note that there is an experiment which could show if the effect mentioned above does or does not exist.

Suppose we have three counters in a vertical plane, d_1 and d_2 being the distances between 1 and 2 and 2 and 3 respectively. Let us suppose that a proton passes through the topmost counter 1 in the right direction to pass through the other counters. It can then be shown easily that the chance of a proton passing through the counter 2 is

$$(\sigma_p + \sigma_n e^{-\sigma q d_1})/\sigma,$$

where σ_p and σ_n are the number of protons and neutrons per c.c. of the substance respectively, and $\sigma \equiv \sigma_p + \sigma_n$. The chance of the counters 1, 2 and 3 being traversed simultaneously by protons is then

$$(\sigma_p + \sigma_n e^{-\sigma q d_1})(\sigma_p + \sigma_n e^{-\sigma q d_2})/\sigma^2,$$

and the chance of protons going through 1 and 3 irrespective of whether a proton or neutron traverses 2 is

$$\{\sigma_p + \sigma_n e^{-\sigma q(d_1 + d_2)}\}/\sigma.$$

The ratio of triple coincidences in 1, 2, 3 to double coincidence between 1 and 3 is therefore

$$R(d_1,d_2) \equiv \frac{(\sigma_p + \sigma_n e^{-\sigma q d_1})(\sigma_p + \sigma_n e^{-\sigma q d_2})}{\sigma\{\sigma_p + \sigma_n e^{-\sigma q(d_1 + d_2)}\}} \qquad (1)$$

If

$$\sigma q d_1 \gg 1, \quad \sigma q d_2 \gg 1, \qquad (2)$$

then the above ratio is $\sigma_p/(\sigma_p + \sigma_n)$, and if either d_1 or d_2 is zero it is unity, as is otherwise obvious. Thus by measuring the ratio of the number of triple to double coincidences between three counters with suitable thicknesses of some heavy material between them, it should be possible to see if the proton-neutron chain mentioned above exists or not.

Dr. Jacobsen and Prof. Clay have independently measured this ratio with d_1 and d_2 corresponding to 10 cm. of lead, and have found that it is unity to within the accuracies of their experiments. If q have the value calculated using the proton-neutron interaction[1] found from considerations of nuclear stability[2], namely, $0\cdot16 \times 10^{-24}$ cm.^{2}, then the condition (2) is satisfied for 10 cm. of lead, and the ratio R should be 0·4 instead of 1. But the above result is not conclusive, since, as we have already pointed out[1], this value of q may easily be in error by a factor of four, as the interaction we have used is not relativistically invariant. We have, however, carried out the above calculation for the scattering both in the system where one of the particles is initially at rest, and in the centre of gravity system, and shown that even in the extreme relativistic case the two cross-sections only differ by a factor four, so that superficially the lack of relativistic invariance of the interaction does not seem to be so serious. In order to get a more definite result, the above experiment should therefore be repeated with at least 50 cm. of lead between each pair of counters.

Points from Foregoing Letters

DR. O. ROSENHEIM and Dr. H. King state that they have converted the primary oxidation product of cholesterol, an unsaturated α-glycol, by further mild oxidation into a most reactive substance of the diosphenol type, called diosterol. In its unusual reducing capacity and other properties, diosterol resembles the cortical adrenal hormone. It is suggested that the latter may arise from cholesterol by stepwise oxidation through the α-glycol, thus explaining the position and function of the hitherto unplaced fourth oxygen atom.

Experiments by P. de Fremery and B. Scheygrond show that the enlargement of the uterus, œstrus and luteinization, brought about by injection of gonadotropic substances in immature female rats, can be completely inhibited by simultaneous injection of antigonadotropic rabbit serum. This latter is obtained by repeated injection of a negligibly gonadotropic extract of male urine in a rabbit.

The oxidation of hæmochromogen (a constituent of the blood), accompanying the oxidation of ascorbic acid when the two are brought together, has been investigated by Dr. R. Lemberg, B. Cortis-Jones and Norrie. The authors discuss the mechanism of this reaction, which leads to the formation of verdohæmochromogen (a bile pigment iron compound) and may throw light upon the physiological hæmoglobin breakdown and the formation of bile pigment.

The behaviour of porphyropsin (a dark purple pigment extracted from the retina of freshwater fishes) on exposure to light has been investigated by Dr. G. Wald, by following the light absorption of porphyropsin solutions under various conditions. The author concludes that, under the influence of light, porphyropsin in the retina of the fish goes through a cycle of changes similar to that previously shown to take place in the case of rhodopsin, the corresponding visual purple pigment in mammals, birds and certain marine fishes.

If ethylene oxide and acetaldehyde are heated together at 400° C., they yield ten times more carbon monoxide than when heated separately. This fact, according to Prof. M. W. Travers and C. G. Silcocks, indicates that in the thermal decomposition of ethylene oxide, although only small amounts of acetaldehyde are detected, nevertheless the intramolecular transformation of ethylene oxide into acetaldehyde actually forms the background reaction which precedes the final decomposition.

Recent work has shown that nitric oxide can inhibit the homogeneous decomposition of some organic molecules, presumably by breaking reaction chains. This may be due to the interaction of the nitric oxide with free alkyl radicals. By following the change in the absorption spectrum of the reaction mixture, Dr. H. W. Thompson and M. Meissner find that in the inhibition of the decomposition of dimethyl ether by nitric oxide, ammonia is formed as the nitric oxide disappears. In the decomposition of diethyl ether, the nitric oxide bands are gradually replaced by a continuum and feeble bands indicative of the presence of methylamine. Both these results are understandable in terms of the reaction of nitric oxide with the methyl and ethyl radicals.

Dr. J. Weiss and Dr. D. Porret report the liberation of oxygen by ultra-violet light in solutions of cerium perchlorate without appreciable decomposition of the perchlorate ion. The authors ascribe the reaction to a photochemical process during which a ceric ion is first excited and then gives up an electron to the water molecule, becoming itself reduced to the cerous state. Hydrogen peroxide may be formed as an intermediate product.

Further experiments on his 'polarographic' test for proteins are reported by Dr. R. Brdička. This test, the author claims, is of value in cancer diagnosis, though some acute cases of inflammation and fever give a similar reaction. He ascribes the effect upon the polarographic curve to the disulphidic groups.

By studying the direction of precession of 'polarized' neutrons in a magnetic field, Dr. O. R. Frisch, Dr. H. von Halban and Dr. Jørgen Koch have found that the magnetic moment of free neutrons is negative, that is, the relative direction of spin and magnetic moment is the same as in the electron. This agrees with expectations based on the magnetic moments of proton and deuteron.

H. J. Bhabha points out that the existence of the exchange interaction between protons and neutrons of high velocity (comparable with that of light), predicted on theoretical grounds, could be checked by measuring the ratio of the number of triple to double coincidences between three 'counters' with at least 50 cm. of lead between each pair of 'counters'.

Research Items

Rise and Decline of Populations

The Galton Lecture of Mr. J. M. Keynes at the annual dinner of the Eugenics Society, on some economic consequences of a declining population, is printed in the *Eugenics Review*, 29, No. 1. The enormous increase of capital during the nineteenth century was partly a result of increasing population, although standards of life and the average period of production were also involved. This period was not lengthened by much more than ten per cent during the fifty years before the Great War, while the annual increment in the standard of life has seldom been more than one per cent. Therefore in a stable population, equilibrium conditions of prosperity can only be maintained by causing a smaller proportion of income to be saved, or by so reducing the rate of interest as to make profitable very large changes in technique or in consumption which involve a much larger use of capital in proportion to output. For the maintenance of prosperity and internal peace we must depend on policies of increasing consumption by more equal distribution of incomes and forcing down rates of interest. A rapidly declining population would involve many severe problems, but even in a stationary population we should be more exposed to unemployment of resources. Sir Walter Layton, in his remarks, agreed with Mr. Keynes's general conclusions, but pointed out that a declining population furnished the best conditions for improving their eugenic quality. Mr. H. D. Henderson stated that the chance of increasing the standard of life in a stationary population is likely to be missed through increasing expenditure on armaments, and concluded that the fall of the birth-rate in Western countries had already gone dangerously far.

Fossil Antelopes and Oxen of the Siwalik Hills

Few areas have shed so much light upon the development of Tertiary ungulates as the Siwalik Hills of India, and Guy E. Pilgrim's account of the antelope and oxen remains in the American Museum of Natural History adds much to our already extensive knowledge of that fauna (*Bull. Amer. Mus. Nat. Hist.*, **71**, 729–874; 1937). The results, drawn mainly from the collections made by Dr. Barnum Brown, throw light on many hitherto obscure problems of identity, affinity and taxonomy. This is particularly so in relation to the Boselaphine group, in which six new genera have been described, and the additional material has enabled the author to redefine the family as characterized by horn-core having a sub-triangular cross-section, produced by a strong anterior and weaker posterior keel united by a flat or slightly convex surface, and a third less definite angle. It has also added to our knowledge of the relationships of the living nylghai, and suggests that the developmental centre of the Tragelaphinae was not in Europe, where the fossil forms show a more advanced stage of evolution than the Siwalik fossils, but that they probably migrated thence from a region still undiscovered, probably in or near northern Africa.

A Puzzling Fossil

The fossil remains of a very puzzling organism are described by D. J. Scourfield (*Proc. Roy. Soc.*, B, Feb. 1937) and it is aptly named *Aniktozoon loganense* (αἰνικτός). Twenty-nine specimens, some of which are in an excellent state of preservation, are used as the basis for the description. They come from the Ludlow Beds of Logan Water, Lanarkshire, almost certainly from the same horizon as *Ceratiocaris* and *Pterygotus* and were collected in and around 1904. At first sight, the clear photographs accompanying the paper suggest a crustacean, but, as the author demonstrates, their reference to this group or indeed to any other group of the Arthropoda cannot be supported by detailed examination. Since they were obviously segmented, the only other known possibilities are the Annelida and the Chordata. They do not agree with the former. The suggestion is put forward that they are to be regarded as representing a lowly chordate stock allied to the Tunicata, but unlike any of the existing forms.

Growth-Rate of *Trochus niloticus*

A detailed investigation of the rate of growth of this species in the Andaman Islands has been made by Dr. H. S. Rao (*Rec. Indian Museum*, 38, 473; 1936). It was found from a statistical analysis of many measurements that the rate of growth in the shell bears an inverse relationship to age as determined by the maximum diameter of the shell between certain stages. The monthly rates of growth at each stage, taken with other facts in the life-history, suggest that in the Andaman Islands the full age may exceed ten years, the diameter from the eighth to the eleventh years ranging from 12 to 14 cm. This is a marked difference from the age estimates of *T. niloticus* which have been made on the Queensland coast of Australia, but Dr. Rao, accepting the differences, attributes them to differences in the conditions of growth in the two areas. In the Andamans, the rate of the growth of female individuals exceeds that of males, but here also, as Dr. A. P. Orr found in the waters of the Great Barrier Reef, the seasons in tropical seas do not appear to cause any differential growth.

Polychætous Annelids of Japan

The examination of an extensive collection of polychætous annelids made by Prof. Okada in the neighbourhood of Seto, Japan, has enabled P. Fauvel (*Mem. Coll. Sci. Kyoto*, Sept. 1936) to add a new species, ***Eunice ovalifera***, and to review the Japanese representatives of the group. In all, eighty-two species have been recorded by various workers; the present collection includes seventy of them. As might be expected from the geographical position of the country, its polychæte fauna indicates a mixture of arctic, temperate and tropical forms. In addition to cosmopolitan species, nineteen are peculiar to the Japanese and neighbouring seas, fifteen are boreal or arctic and twenty-six are tropical. It is suggested that the pelagic larval stages of many of them may have been introduced by the great ocean currents reaching the coast. The Kuro-Siwo brings up the warm water from the tropical Pacific to the west coast, and the Oja Siwo comes down from the Arctic Ocean to the north coast.

Cytology of Brassica Hybrids

CROSSES between radishes and cabbages have been made previously in Russia and Japan, and no chromosome pairing was found in the F_1 hybrid meiosis. Dr. R. H. Richharia (*J. Gen.*, 34, No. 1), in a study of the F_1 hybrid between radishes and Brussels sprout, found a maximum of six bivalents, both parents having $2n = 18$ chromosomes. This difference in chromosome pairing may be ascribed to the different varieties used. Brussels sprout, curly kale and radish all showed 9 bivalents regularly in diakinesis, while the cabbage had a ring or chain of 4. The maximum number of secondary associations was five in curly kale and four in the radish. Twenty-one F_1 hybrids were examined at meiosis, and about half were hypotetraploids with frequent trivalent and tetravalent chromosomes, the hybrids showing great variation. Six principal types of chromosomes can be distinguished in *Raphanus sativus* and *Brassica oleracea*, as well as in *B. chinensis*, *B. Rapa* and *B. pekinensis* which have $2n = 10$ chromosomes, and their F_1 hybrids. The last three species show five large and five small bivalents at meiosis, except that in *B. Rapa* the distinction is less marked. In *B. pekinensis* × *B. Rapa* there are occasionally two free univalents, and 'non-disjunction' sometimes takes place. Studies of secondary pairing in these species did not lead definitely to a primary basic number.

Subsidence of East Tokyo

IN some parts of Tokyo, and especially in the districts of Hukagawa and Honzyo on the east side of the River Sumida, recent re-levellings show that there has been a notable sinking of the surface (NATURE, 137, 281; 1936). In the centre of the city, in the Marunouti district, as Prof. N. Miyabe points out (*Bull. Earthq. Res. Inst.*, 15, 102; 1937), many buildings have apparently risen above the ground, one at the rate of nearly 3 in. a year. In both regions, a layer of alluvial soil, 108 ft. thick in the former and 65 ft. in the latter, rests on a hard bed of tertiary rock. A little more than a year ago, two special bench-marks were installed in Hukagawa and Honzyo. They were fixed into the tops of tubes driven down into the tertiary bed. Precise levellings carried out in April and October 1936 showed that the ground-level was lowered 1–2¼ in. with reference to the surface of the tertiary layer. In the Marunouti district, the buildings rest on piles also penetrating the tertiary rocks. Levellings carried out in August 1929 and October 1936 reveal a depression of very nearly the same amount as the apparent uplift of the buildings. Thus, Prof. Miyabe concludes that the subsidence is due, not to any downward warping of the crust, but to the contraction of the surface soil.

Magnetic Properties of Silver Difluoride

THE magnetic properties of silver difluoride, AgF_2, are of interest in connexion with the question of the arrangement of the atomic linkings in this compound. The corresponding oxide, AgO, is practically non-magnetic, and previous determinations have shown that the difluoride has only a very small susceptibility. This result has now been confirmed (E. Gruner and W. Klemm, *Naturwiss.*, 25, 59; 1937); but it has also been found that at low temperatures (– 183°) much higher values of the susceptibility are obtained, the substance becoming weakly ferromagnetic, with a Curie temperature of about – 110°. It is considered that the compound contains Ag.Ag linkings, the spin moments being anti-parallel at ordinary temperatures, becoming, in part, parallel at lower temperatures.

Steam Tables

THE issue of the *Journal of Research of the Bureau of Standards* of April contains a paper of sixty pages by N. S. Osborne, H. F. Stimson and D. C. Ginnings in which their determinations of the properties of water and steam between 100° and 374° C. are described. The work was rendered necessary by the extended use of higher pressures and temperatures in steam engineering, and the results obtained have been co-ordinated by international conferences in order to secure closer agreement in the steam tables embodying recent international research. The method used is to heat electrically a known mass of water and steam in an insulated calorimeter, observing temperature and pressure of the contents and the energy communicated. This is done either with the contents fixed or with withdrawal of liquid or vapour at will. Tables are given of the principal data from each type of experiment, and the final results are embodied in tables of the specific volumes of liquid and vapour in c.c. per gram, the saturation vapour pressure in kilos per sq. cm., the latent heat, the enthalpy (total heat), and the entropy of liquid and of vapour in international steam table calories (4·18605 international joules) per gram and the Clapeyron factor $T\frac{dp}{dT}$ at 5° C. intervals from 100° C. to 365° C. and at smaller intervals to 374·15° C., the critical temperature.

Characteristic Curves for Meteors

THIS is the title of a very interesting paper by Mr. J. G. Porter (*J. Brit. Astro. Ass.*, 47, 6, April 1937), in which he investigates various problems connected with the size, velocity and composition of meteors, and especially the relationship between these and the luminosity. He carries out a very exhaustive analysis, basing his formula on the atmospheric resistance on Davidson's formula (*J. Brit. Astro. Ass.*, November 1913). Mr. Porter finds that there should be a difference of about ten miles in height in the appearance of the fast and slow meteors, that is, those moving with velocities 40 and 10 miles a second, respectively, and the results of the Arizona Expedition largely corroborate this theoretical deduction. Meteors seen at low heights are shown to have lost a considerable fraction of their velocity, and must also be fairly large, generally speaking. It does not follow that they are very bright, because some of them may be of the type of the pyroxene and olivine minerals, possessing high volatility and low luminosity when heated. Mr. Porter hopes to continue his investigation, especially on the question of velocities, from which he may be able to form an opinion on the relative frequency of hyperbolic orbits.

Modern Aristotelianism

By Prof. H. Levy, Imperial College of Science, London

DR. H. DINGLE's plea in NATURE of May 8 for a return to experimental criteria in science, is timely. One may differ from him over the grounds upon which it rests, or over the stress he places on certain points: it is difficult to imagine any genuine disagreement with his main contention.

It must be realized, however, that since the days of Galileo, much has happened in science, not only in the extent of the fields that have been explored, in the nature of the instruments that have been designed to facilitate investigations, but also in our understanding of the relation between the subject matter of science, and those who pursue its study. It is never easy for those who are absorbed in the detailed technique to appreciate the philosophy and the methodology underlying their practice, or even to recognize when and why they are establishing new traditions. To-day we are witnessing such changes, and Dr. Dingle's protest will have been effective if it has the effect of forcing us to examine, in an objective way, the path that is being trodden.

Mathematics is one of the instruments the power of which since the days of Galileo has reached a completely new level. Its success in analysing the relations between empirical data, and in exploring the implications of speculative theories, has tended so to impress the mind, not of the mathematician alone, as to confer on it almost the status of an independent and self-constituted science. It is in directing attention to this dangerous intoxication with symbols that Dr. Dingle's protest is well-founded.

This situation is, however, not to be met merely by a reiteration of the Galilean basis of science, as Dr. Dingle does, or by falling into the error of identifying physics with the whole of science, as Dr. Dingle, following the lead of the mathematician, also does, but demands a positive statement of the place of mathematics and its attendant speculations in the process we call science.

For mathematics is essentially an *instrument* of discovery, and no instrument that has to tell us about the behaviour of the world can function in a vacuum. It works on something, and that something must be extracted from the experience of men in the objective world. Now the trouble begins to show itself in the first instance in the fact that the mathematician can handle ideas and speculations apparently divorced from any empirical background. He starts with *given* assumptions convenient to himself and his mathematical equipment. I say *apparently* with deliberation, because since the mathematical craftsman is primarily interested in the logical coherence of his analysis, he and those others who cannot follow his intricate symbolism, find themselves less and less disposed to examine the origin of the ideas on which he is experimenting with his mathematics. "Mathematics," he would say, "is the formulation of rational relations between any given set of ideas." He does not inquire whence the ideas come, what material circumstances in the world about him have stimulated them, how far they are a direct reflection of the changing situation in the objective world, or how far they are simply a novel combination of such stimulated ideas. As soon as this issue is raised, we can see how futile it is to tilt at the *a priori* principles of the Aristotelians; there are none. What has to be exposed to view is the human experiential basis on which the principles unconsciously rest.

If it is true that the *given* ideas of the mathematician do not come as a miracle out of the void, that they are in some sense 'transformed' observations, then whatever assertions he may make that he can dispense with observations, he is nevertheless pursuing an aspect of inquiry subsumed under the phase—"The formulation of rational relations between 'transformed' sense observations". How close this seems to be to Dr. Dingle's position, judging from his statements, as he judges from those of Prof. Milne, may be seen by comparing this phrase with his own definition of science:

"Science is the formulation of rational relations between sense observations."

Like Sir Arthur Eddington, however, Dr. Dingle is better than his definition, for what he is really pleading for is something slurred over in his definition, the conscious interplay and mutual directiveness between theory and experiment. Every theory and every experiment rests on an interwoven history of both. "Science," one might have expected him to assert, "is the empirical-cum-rational analysis and directing of natural process." Of course, even the speculative cerebrations of mathematicians are natural processes, and in that sense the subject of scientific interest, not to physicists, but to psychologists; or, when a mathematician asserts that by thought alone (whatever that is) the whole of physics can be deduced, of interest to medical psychologists. What we are here concerned with is the results of that cerebration, because they purport to state something about physics.

Two criteria are required in their examination. One will enable us to judge when results are such as to justify incorporation in the expanding body of scientific fact and generalization. That test is a practical one, and in the final analysis must be applied by the experimenter. Even a theory based on so-called *a priori* principles, where it purports to express itself in terms of observables, can have this test applied to it. Where it cannot be so expressed, it does not fall within the ambit of science: it is mathematically experimental speculation. Provided we recognize its nature and do not attempt to dress it up in the outward guise of science, who can assert that the experience so gained is of no value in the pursuit of legitimate science? It is the emergence of this class of inquiry that distinguishes the present epoch in mathematical physics from that of Galileo.

To assert that such studies *may* have a secondary place in suggesting other more directly scientific inquiries does not provide the justification for their indiscriminate pursuit. Some other criterion must be found. ". . . hundreds of pages, and thousands of pounds are being spent . . . by a growing army of 'research' workers . . ." writes Dr. Dingle as evidence of the folly of the new vogue in universes. Here the appeal is certainly not to any criterion directly or indirectly implied in his definition of science, but to a social judgment. He points the finger at something which he conceives, rightly or wrongly, to be anti-social, because it involves wastage on studies not directly scientific. This is a very significant matter. It is importing a consideration that has become more and more prominent in the columns of scientific journals during the past few years. It asserts that the justification for a scientific inquiry is not entirely a narrow scientific one but rests also on its social value. It is an admission of the interconnexion of science with society, that the direction of scientific development, and therefore that the body of theory and practice embraced within science at any given time, is dependent on fundamental social, besides scientific, considerations. That he makes this judgment is itself a fact : hence on his own definition of science he must find a rational place for it within that definition. As it stands there is none. If he objects to the work of the mathematical speculators, he can do so at present only with respect to these phrases that purport to deny the necessity for observation. He cannot object to the expenditure of funds on such investigations, or to publications that are simply mathematical exercises in fictitious model universes.

Just as soon as we face up to this, these various problems begin to fall into a more integrated scheme. We state the position thus :

(1) Science is a social effort to understand, control and fashion Nature in accordance with developing human needs and desires.

(2) The method of science is an ever-growing and ever-deepening integration between experiment and inference, emerging in successive generalizations and successive applications to practice.

(3) Mathematics is an instrument designed to assist in the drawing of inferences from sets of data or of ideas, or what amounts to the same thing, to test such sets for their logical consistencies and inconsistencies. It is in the exposure of the latter that the deficiencies in the original data are made plain. Out of these deficiencies emerges a drive towards further experimentation.

Now when the mathematics under (3) can be regarded as accessory to the inferential processes of (2), and so can be integrated with experimental development, it can be said to have a place in science. This would include that part of pure mathematics that in the widest possible sense can be looked upon directly or indirectly as 'instrument-making'. In no circumstances can (3) ever replace (2).

To decide that a particular series of investigations ought to be encouraged, and, in particular, that it ought to receive the blessing of dominant scientific groups—and this is ultimately the question raised by Dr. Dingle—equally implies deciding to discourage other investigations, since the income to science is limited. Such a decision can emerge only from a thoroughly clear conception of what is implied in (1). It involves planning science pure and applied in its social context, and not following it indiscriminately for intellectual, financial or æsthetic interest ; we are very far from that at the present moment, as the leader columns of NATURE amply testify. Dr. Dingle is therefore tilting at one of the irrational features of social and scientific life. The fact that such irrationalism manifests itself in bold assertions of the type Dr. Dingle rightly deplores, that (3) can replace (2), is in such circumstances a natural consequence of the persistent refusal of scientific men to devote as much careful thought to science as a movement as they are prepared to give to their specialized fields.

Royal Observatory, Greenwich Annual Visitation

THE annual visitation of the Royal Observatory, Greenwich, by the Board of Visitors took place on June 5.

The report of the Astronomer Royal includes for the first time an account of the work of the Nautical Almanac Office, which has been made a branch of the Observatory, with Mr. D. H. Sadler as a chief assistant and superintendent of the Office. It is of interest to recall that the *Nautical Almanac* originated with Maskelyne, the first volume appearing in 1765, the year following his appointment as Astronomer Royal, and that the almanacs for fifty years were produced under his direction.

The Nautical Almanac Office has recently undertaken the compilation of an *Air Almanac*, specially adapted to the requirements of aerial navigation. The first issue will cover the last three months of the present year. The *Air Almanac* will give the air navigator the astronomical data in a convenient form ; but the present methods for the subsequent computation are not suitable for conditions in the air. Extensive altitude and azimuth tables will be computed in the Office, which will give the solution of the spherical triangle directly.

The astronomical observations at Greenwich during the past year suffered inevitably from the poor observing conditions, the year having been one of the most cloudy on record. 6,573 transit observations were obtained, including 107 observations of the sun and 86 observations of the moon. The observations of the moon continue to show a decrease in the correction required by the longitude according to Brown's tables. These tables, however, include Newcomb's great empirical term and, when comparison is made with pure gravitational theory, the moon shows an increasing departure from its computed place. This departure is produced by variations in the rate of rotation of the earth. The accumulated effect of such variations in a year may at times amount to one second. The best astronomical clocks are scarcely sufficiently uniform in rate to detect such an error. It is possible that a clock of the vibrating quartz crystal type would have the desired accuracy. Such a clock is under construction for the Observatory at the National Physical Laboratory and should be of material help in improving still further the accuracy of the time signals sent out from the Observatory, which are necessarily based on predicted clock errors.

The Observatory controls, by means of hourly signals, the Post Office Talking Clock, a service that was inaugurated by the Astronomer Royal on July 24. The calls on this clock are at the rate of ten million a year. It is intended to install similar clocks in other large centres.

The observations made with the Cookson floating telescope on a uniform programme for the past twenty-five years are under discussion. These observations have shown that the mean position of the Pole has not varied, during this period, by more than two or three feet.

The 28-inch refractor is being used for the general re-measurement of all double stars in the northern hemisphere, within the range of the telescope, that show appreciable motion in a decade. 692 observations on 238 double stars were secured. A comparison image micrometer has been constructed to facilitate and improve the accuracy of the measurement of close pairs. The filar micrometer will continue to be used for the wider pairs.

The projection method of measuring photographs has been applied to the micrometer used for the measurement of the stellar parallax plates. The star image and the micrometer wire system are projected on a screen, which is adjusted to the measurer's most comfortable reading distance, and both eyes are used, so avoiding eye fatigue.

Sunspot activity has increased greatly during the year. There were about twenty-five groups the maximum area of which exceeded 500 millionths of the sun's hemisphere. An intense magnetic disturbance, the largest for ten years, was associated with a large spot, the meridian passage of which occurred on April 24. The study of bright eruptions on the sun has been continued. These are becoming much more frequent with increasing solar activity; 72 were observed during the year. A close relationship between these eruptions and sudden fadings of short-wave radio transmissions has been established. The spectrohelioscope is being used also for measures of radial velocities, mostly in connexion with dark markings associated with sunspots, and of the maximum intensities of prominences and of bright and dark flocculi.

Magnetic observations were made at Abinger throughout the year. The mean values of the magnetic elements for the year 1936 were as follows:

Declination . . .	W. 11° 20·0′
Inclination . . .	66° 41·8′
Horizontal intensity .	0·18524 gauss
Vertical ,, .	0·43007 ,,

Preliminary investigations in connexion with the new reversible transit circle have occupied much time. The figuring of the pivots was completed, the maximum departure of each pivot from the circular form being about one-twelfth of a micron. The errors of the one-degree divisions on the 24-inch fixed glass circle have been determined; these show a range of only 0·4″. Observations with the transit micrometer revealed some anomalies that required extensive investigation, and that necessitated the return of the micrometer to the makers for correction.

The slit spectrograph for use with the 36-inch reflector has been completed. It has optical parts made of ultra-violet crown and flint glass, combined with quartz, being intended specially for work in the ultra-violet region. It can be used with a dispersion of either one or three prisms.

During the year, Mr. W. Bowyer, who had been in charge of the Time Department, retired after forty-four years' service and Mr. D. J. R. Edney, secretary, retired after nearly forty-five years' service.

The Astronomer Royal concludes his report with a reference to the difficulties connected with the installation of mercury vapour discharge lamps for lighting certain streets in the vicinity of the Observatory. Representations have been made to the Greenwich and Lewisham Borough Councils of the probable effects of the extension of such lighting along the roads across Blackheath. The two Borough Councils have expressed their desire to avoid interference with the work of the Observatory, and extensions of this system of lighting have been held in abeyance, so that possible alternatives could be thoroughly investigated.

Rothamsted and Agriculture

ANNUAL INSPECTION OF THE ROTHAMSTED PLOTS

A LARGE and representative gathering met at Rothamsted on June 4 for the annual inspection of the field plots and the laboratories. The Right Hon. W. S. Morrison, Minister of Agriculture, was present. Prof. H. E. Armstrong, recently elected chairman of the Lawes Agricultural Trust Committee, was unfortunately unable to attend owing to ill-health, but sent the following message:

"My connexion with Rothamsted goes back to 1870, when I first learnt to know Sir John Lawes and Dr. Gilbert. I am the only member of the original Trust Committee, established in 1898. I claim to have been instrumental in bringing both Sir Daniel Hall and Sir John Russell away from Wye here. I have therefore accepted the Chairmanship of the Trust Committee with singular satisfaction, though I know full well that it is now beyond me to exercise much constructive control.

"We are at the close of our first critical period. We have acquired the Trust and purchased our release from Sir John Lawes' conditions. We owe this advance to our present Director: he has carried out a task of greatest difficulty, with conspicuous success, for which I, as Chairman, would thank him on behalf of my colleagues and the friends of agriculture in general.

"At first the work of the Trust was confined to the experimental fields, laid down by Sir John Lawes and Dr. Gilbert—no funds were available for other work. Sir John Russell, with extraordinary acumen, by his pertinaceous appeals, has secured funds enabling us to extend the ambit of our inquiries : by his genius we have acquired the estate and so extinguished our obligation. According to the Trust Deed, the Committee has the sole management, superintendence and direction of the Trust and of the investigations and experiments to be carried on. Authority rests with the Committee. This is not sufficiently recognized.

"We shall need now to frame a constitution to govern the future, by no means an easy task. Studying the work done during all but seventy years, I have long formed the very definite opinion that the 'living soul' does not enter sufficiently into our activities. We need to force our workers more out into the field.

"Sir John Lawes began his experiments in prehistoric times, in a controversy with Liebig over the need of wheat for nitrogen beyond that derived from natural sources. He was thereby led to initiate the systematic trials embodied in the plots, now known to all the world, using various mineral salts in conjunction with either ammonia or nitrates. Lawes did not consider that much more would be learnt from the crops, apart from the periodic effect of climatic variations. He thought, however, that in course of time the soil might be affected. It is to be feared that he inaugurated a policy which, if persevered in, may be ruinous to the soil.

"Lawes provided only for the continuation of the plot experiments. When the Development Commission divided agricultural inquiry into sections, it assigned *Soil* to Rothamsted. There were no funds for the work but the difficulty was overcome by the munificence of the Goldsmiths' Company. It is most unfortunate that our wings were thus clipped to the soil. The agricultural artist cannot work in a single medium—the policy of the Commissioners was a wrong one, wherever applied—equally at Aberdeen and Cambridge. As a consequence we have been far too much confined to academic laboratory work—animal and plant have scarcely been in the picture.

"Rothamsted policy in future must be to make food production and nutritional values—A.P.H.'s benenutrition—the main study. No higher work can be undertaken. A great and hopeful future is before farming, if only it be properly led. Special care must be given to training men for its service. To this end, the teaching of chemistry and physiology in general must be made effective in school and university. Training must be given in the use of eyes and especially in the exercise of scientific thought—of thought based upon knowledge.

"Agriculture has a sufficient task before it. The work done by Sir John Lawes is a great one—who shall say what his influence has been in introducing systematic inquiry into farming ? Thus far, however, he has taught us mainly what not to do—the course usually followed in the most fruitful inquiries but not to be long maintained."

In the absence of Prof. Armstrong, Sir Bernard Greenwell presided. Mr. Morrison, speaking of Rothamsted Experimental Station, said that it is a remarkable example of State aid and private enterprise, and that the suspicion with which research used to be regarded by the practical man has largely passed away. Mr. Morrison then reviewed some of the broad considerations which have guided him in developing his recent agricultural policy. Soil fertility is the most fundamental aspect of the agricultural problem. With a fertile soil, production can be adapted to changing circumstances and emergencies, whereas a depleted soil is unequal to the demands made upon it. For this reason, he has taken steps to encourage measures of soil improvement, and in the technical matters arising out of his proposals for increasing the use of lime and basic slag, he has not hesitated to call upon the special knowledge that Rothamsted can provide. He reminded his audience that in addition to the material basis of farming, the soil and the livestock upon it, there must also be knowledge.

Sir John Russell, who followed, took up this theme and showed how the object of the work at Rothamsted has always been this search for information. Some of the investigations undertaken seemed at first to be remote from practice, and indeed appeared to have no immediate application. Sir John proceeded to quote many instances in which such investigations have turned out to be of the greatest practical importance and usefulness. He mentioned some of the recent Rothamsted work on lime and basic slag that will be of special service in advisory work arising out of the new proposals. In spite of the difficult six months just passed, Broadbalk, now in its ninety-fifth year, looks surprisingly well, and its interest has been enhanced, rather than diminished, by the fallowing system adopted in recent years. The visitors also inspected the modern rotation experiments on present-day problems in soil fertility.

The proceedings were favoured by ideal weather conditions.

EMPIRE AGRICULTURAL OFFICERS

On June 3, the annual gathering of agricultural officers on leave from various parts of the Empire took place at Rothamsted at the invitation of the Imperial Bureau of Soil Science, when some eighty visitors representing seventeen Empire countries were present. This function not only enables members of the overseas agricultural services to make contact with the staff of the Soil Bureau and Rothamsted workers, but also affords a valued opportunity for meeting each other. In his speech from the chair, Lord Bledisloe outlined the development of the Soil Bureau during the eight years of its existence. He mentioned that the year's output of scientific papers in soil science now amounts to the astonishing figure of about 4,000, written in twenty different languages. The task successfully undertaken by the Bureau is to sort out this great mass of literature and make available to workers in any part of the Empire the latest information from all countries relating to soils, crops and manures. The Technical Communications published by the Bureau are in increasing demand, and several of them have attained the status of standard and authoritive works. Lord Bledisloe, speaking with special knowledge of agricultural conditions in several Dominions and his own close acquaintance with agricultural research, expressed his conviction that money spent in the investigation of farming problems is an investment that will give returns out of all proportion to the original outlay.

The visitors spent the morning examining the plots on the Rothamsted farm and the afternoon was devoted to a tour round the laboratories.

Science News a Century Ago

Wheatstone and Cooke's Electric Telegraph

ON June 13, 1837, Wheatstone and Cooke took out their first patent for "giving signals and sounding alarms at distant places by means of electric currents". Among the instruments included in this patent were those with five needles and two needles. An experimental line was laid down between Euston and Camden Town in 1837, but the first actual working telegraph was that joining Paddington and West Drayton, a distance of 13 miles, erected in 1838–39. Examples of these early telegraphs are preserved in the Science Museum.

J. D. Forbes and von Buch

IN the journal of his travels on the Continent in the summer of 1837, J. D. Forbes in his notes on the six weeks he spent at Bonn wrote under the date June 15: "Finding Von Buch here, I left my letter from Professor Jameson for him, and in the course of an hour he called. I was instantly charmed with the kindness and simplicity of his manner; and as I could see at once that his character for singularity was not one which I had any reason to fear, we were immediately excellent friends".

The next day the two met again, and had conversation on Forbes's views on the Pyrenean springs and von Buch's paper on craters of elevation. "As to the history of the elevation theory," wrote Forbes, "he states that he first pointed out four elevations belonging to different epochs—all of which are well seen in Grimm's map of Germany—chiefly by tracing the river courses. The mountains about the Elbe form one system, the Taunus mountains another, the Schwartz-Wald a third, and the Alps a fourth; . . . pointing out, as evidence of the comparatively recent elevation of the latter, the inclination of the tertiary strata. He gives Elie de Beaumont the credit of finding exact criteria for determining epochs of elevation, but attached little probability to the theory of parallelism on a large scale, considering the systems of chains rather overdone. . . ."

On the afternoon of June 16, Forbes observed the magnetic dip at Poppelsdorf and afterwards called on Prof. Gustav Bischoff "who showed me the sheets of his work on the temperature of the earth. . . . He has also made experiments on the cooling of spheres of melted basalt, having a diameter of twenty-seven inches, and others of nine inches. . . . Von Buch came in as we were examining these".

"Bischoff also took a piece of basalt, split in two, and tied together with twine . . . fixed it in the axis of a cylindrical mould, and poured molten iron round it. This latter in cooling, (according to him) expanded and squeezed the basalt. Certainly, many dykes of basalt in iron appeared, very prettily, but I doubt the squeezing, especially from the large cavities left in the iron, a fact which was also noticed by Von Buch: whether there would be squeezing or not, would be somewhat difficult to predict. . . ."

Captain George Back's Expedition

ON June 15, 1837, a general meeting was held of the subscribers to the fund raised for sending Captain Back in search of Captain John Ross. The meeting was held in the rooms of the Royal Geographical Society in Regent Street, Admiral Sir George Cockburn being in the chair. The total amount subscribed had been £6,578 19*s.* 10*d.* and after paying all expenses there remained a balance of £619 4*s.* 6*d.* The meeting agreed with the suggestions put forward by the committee that three pieces of presentation plate should be given to Captain Back, Captain James Clark Ross, and Captain Maconochie, the last of whom had organized the expedition, and that £300 should be given to the Sailors' Home, Wells Street. The Hudson Bay Company had waived the whole of its claim for the amount due for supplies provided for the expedition in North America.

Dalton on the Constitution of the Atmosphere

BEFORE adjourning for the long vacation, the Royal Society met on June 15 to hear the reading of several papers, among which was one by Dalton entitled "Sequel to an Essay on the Constitution of the Atmosphere published in the Philosophical Transactions for 1836; with some account of the Sulphurets of Lime". An abstract of the paper said: "The author communicates in this paper an account of the investigations on the constitution of the atmosphere, which have engaged his attention during a long period of years. He enters into an examination of the comparative advantages of the three methods which are most in use for analysing common air, namely, firing it with hydrogen in Volta's endiometer, or abstracting the oxygen by means of nitrous gas and quadrisulphuret of lime; and details the precautions to be taken in the employment of each of these methods, and the degree of accuracy to be expected from the results under different circumstances. He then relates numerous experiments made on air obtained from great heights, from which he is led to the conclusion that the proportion of oxygen to azote in the atmosphere on the surface of the earth is not precisely the same at all places and times. . . ."

National Board of Health

AN editorial in the *British Annals of Medicine* of June 16, 1837, contains the following suggestion: "The necessity for the establishment of a Board of Public Health is forcibly pointed out by the fact that the mortality during the last 10 years—years of peace too—has been progressively increasing in Sweden, Prussia, France and England. This is proved by authentic documents. Are medical men aware of this fact? Not generally, we believe, because no public board exists to bring the conviction home to their minds. Yet—amidst all the splendid discoveries of the century, the accession to our knowledge of disease and the new remedies which have sprung into existence—people die faster than they did 10 years ago. A vast opposing tendency yet to be investigated, carries us against the full tide of improvement. . . . So soon as public attention can be brought to bear on the question, a Board of Health will, we do not doubt, be established. As Dr. Mohry has remarked, the apathy of the College of Physicians, and of the persons accidentally at the head of the profession, has alone retarded the establishment in this country of something corresponding to the *Conseils de Salubrité*, and *Sanitatsbehörde* in France and Germany. . . . There would be three principal functions of the new institution; to publish a report of the state of public health every year; to provide or point out measures for its amelioration; and to control the medical profession. . . . The Annual Sanitary Report, if properly executed, would be an invaluable contribution to science."

Societies and Academies

Dublin

Royal Irish Academy, March 16.

J. J. Dowling and T. G. Bullen: Precision measurements with a radial deflection oscillograph. An extra pair of concentric cylindrical electrodes are fitted between the XY deflector plates and the screen of a gas focused cathode ray oscillograph. Employing a double frequency circular time-base locked to the signal frequency a so-called Radioid curve (resembling a Limaçon) is obtained, and the position of the node around the time base circle serves to measure phase or frequency differences in high-frequency circuits. Another application is as a 'time-comparator', and comparisons of the periods of a pair of two-seconds pendulums to within five parts in a million are easily obtained while the pendulums are executing twenty swings. An improved design of tube is described and further work promised.

Paris

Academy of Sciences, April 26 (*C.R.*, 204, 1225–1284).

Samuel Eilenberg: Slight enlacement.

Shiing-shen Chern: The geometry of a differential equation of the third order.

Nikola Obrechkoff: The zeros of some classes of polynomials.

Pierre Chevenard, Louis Huguenin, Xavier Waché and Albert Villachon: New alloys of the elinvar type susceptible of structural hardening. Balance springs of elinvar, although giving excellent thermal compensation, are much softer than ordinary steel springs. The elinvar alloy can be modified by the addition of titanium. The modified alloy, while retaining the thermal advantages of elinvar, has an elastic limit approaching that of carbon steel.

Mlle. Jacqueline Hadamard: The dielectric constants of cyclohexane and benzene. The results given, for which an accuracy of 0·1 per cent is claimed, are compared with those of earlier workers.

Georges Nadjakoff: The nature and origin of the large ions of the atmosphere. The author's observations are in agreement with the view suggested previously by other workers, that there is a close connexion between the number of large ions and the smoke of towns.

J. J. Placinteanu: The wave function of the photon.

Marcel Laporte: The production of white light by the electrical luminescence of xenon.

Jules Farineau: An attempt at photometry in the field of the soft X-rays; application to the study of the free electrons of metals.

Georges Mano: The relation between the kinetic energy and path of the protons. The case of artificial transformations.

Roger Chatelet: A thermo-chemical application of thermal analysis to the formation of the eutectoids of the binary alloys.

Clément Courty: The diamagnetism of iodine solutions. An attempt to trace a connexion between the colour of iodine solutions in different solvents and their magnetic properties.

Ernest Toporescu: The action of sulphur on silver.

Albert Portevin, Georges Chaudron and Léon Moreau: Contribution to the study of the role of gases in metals. Study of the variations in hardness, conductivity and crystalline parameter after removing the gases at the ordinary temperature, after annealing and after charging with hydrogen by electrolysis. Data are given for iron and aluminium.

Hubert Forestier and Richard Lille: The variation of catalytic activity of ferromagnetic oxides at the Curie point. The experiments cited establish a clear relation between the magnetic transformation point and the catalytic properties of ferromagnetic oxides.

Georges Denigès: Reactions for the identification of tellurium of microchemical order.

Paul Renaud and Georges Costeanu: Anomalies in the action of steam or of ammonia on sodium or hæmatoxylin.

Maxence Meyer: The formation of hydrocarbons in the thermal decomposition of the α-ethoxyacids.

Panos Grammataticakis: The action of mixed organomagnesium compounds on the phenylhydrazones of the symmetrical alkylphenylhydrazines. A new method of preparation of the symmetrical alkylphenylhydrazines.

Paul Fleury and Mlle. Suzanne Boisson: The action of periodic acid on lactic and pyruvic acids. In the oxidation of lactic acid by periodic acid, two primary products are aldehyde and methyl alcohol.

Jacques Duclaux: The transparency of the air in the arctic regions.

Paul Becquerel: The death of the plant cell by freezing in liquid nitrogen at −190° C.

Marcel Mascré and René Paris: Scoparine (scaparoside) from *Sarothamnus scoparius*.

Auguste Chevalier and Pierre Viguier: The double origin of cultivated rice and the West African centre of rice dispersion.

Jean Renaud: A *Saccharomyces* presenting curious anomalies in its sexuality due to a dikaryotic state of its zygospores.

Stefan Nicolau and Mme. Léonie Kopciowska: Data on the coloration and morphology of some viruses in animal tissue.

Alexandre Besredka and Ludwik Gross: The immunization of the fowl against sarcoma by the intracutaneous method.

Paul Valade: The cancer-forming activity of methylcholanthrene.

Amsterdam

Royal Academy (*Proc.*, 40, No. 4; 1937).

R. Weitzenbock: Remarks on trivectors.

F. M. Jaeger and L. Bijkerk: Investigations on the complex salts of the racemic and optically active cyclohexanediamines with trivalent cobalt and rhodium (4). Crystallographic properties of the optically active tri-cyclohexanediamine cobalt salts and on ethylenediamine-cyclohexanediamine cobaltic salts of this series.

J. le Heux and A. de Kleyn: Investigations on the isolated eye muscles of the rabbit during the positional nystagmus in acute alcohol poisoning.

T. L. de Bruin, J. N. Lier and H. J. van de Vliet: The Zeeman effect of doubly ionized cerium, Ce III.

T. L. de Bruin: New terms in the spark spectra of argon, A II and A III.

J. Popken: An arithmetical property of certain integral functions (3).

C. Visser: Certain infinite sequences.

N. H. Swellengrebel, A. de Buck and H. Kraan: Further investigations on 'healthy' human carriers of *Plasmodium vivax* in North Holland.

Capetown

Royal Society of South Africa, April 21.

Archæology of the Oakhurst Shelter, George. (1) A. J. H. Goodwin: Course of the excavation. (2) A. J. H. Goodwin: Disposition of skeletal material. (3) M. R. Drennan: Skeletal material. (4) J. F. Schofield: The pottery.

P. W. Laidler: An unusual grooved stone.

Geneva

Society of Physics and Natural History of Geneva,

March 4.

R. Wavre and G. Bilger: Some polygons of similar attraction. The authors establish that a homogeneous regular polygon creates at every point external to the plane the same single layer logarithmic potential as the radii of the circumscribed circle touching the angular points.

March 18.

E. C. G. Stueckelberg: (1) The analogy between the retarded potential of quantum physics and classical physics. A Lagrangian function is established by a system of *n* particles which react with each other. This function is invariant, but has the defect of containing higher potentials. However, the interaction terms can be expressed in quantum physics, where they give the necessary relations. (2) The establishment of the formula of retarded potential in quantum physics. By means of electrodynamics with multiple time quanta, the interaction terms established in the previous communication are here established rigorously to the second approximation in *e*.

E. Cherbuliez and J. Jeannerat: Researches on casein. The authors have improved the method of separation of casein into various fractions. They show that one of these fractions, δ, is identical with a protein body, proteose, isolated by Hammarsten from the products of the action of rennet on casein. Hence proteose appears to be an original constituent of the milk and not a cleavage product due to the action of rennet on casein.

F. Chodat: The enzyme decoloration of the petals of the poppy.

E. Briner and E. Perrottet: (1) The problem of the removal of ozone from air and from oxygen. The properties of air and oxygen free from ozone. The authors describe the method employed for removing ozone from ordinary air and ordinary oxygen. They point out the differences in oxidizing power of air and of oxygen free from ozone. (2) A method of analysing very dilute ozone: the determination of the ozone concentration in the air of Geneva. The application of the method described at the meeting of February 4, 1937, by the same authors has given for the concentration of ozone in the air of Geneva the value 7×10^{-8} with an error of $\pm 2 \times 10^{-8}$.

April 29.

F. Chodat and R. Cortesi: Study of buffer action in culture fluids. The authors have observed fluctuations in buffer action in the culture of *B. mycoides*; a minimum is reached at the end of the first week, as soon as the gelatine medium is liquefied.

P. Rossier: A simplification in the calculation of the magnitude of a star, relating to a receiver with two sensibility maxima. The author replaces the usual formula by the simpler one of Stirling, some factors of which can be neglected in certain cases. This leads to a marked simplification in the calculations.

R. Sulzer: The comparative study of the attitude of an animal deprived of a labyrinth and the attitude of a normal animal standing on a slope. The author studies the disturbances of equilibrium produced in the guinea pig by the unilateral suppression of the labyrinth.

G. Tiercy and Ch. Golaz: The law of the variation with altitude of wind velocity. The note gives three numerical tables established with the view of controlling the theory by observation.

Melbourne

Royal Society of Victoria, April 8.

Elizabeth A. Ripper: (1) Some Stromatoporoids from Griffith's Quarry, Loyola, Victoria. This locality has yielded four species: *Clathrodictyon regulare* (von Rosen). *C.* aff. *chapmani* Ripper, *Stromatopora typica* von Rosen, and *S. bücheliensis* (Bargatsky), as well as a *Stromatoporella* not here described. This fauna has little in common with that of the Yeringian limestone at Liludale, and the abundance of *C. regulare* and *S. typica*, two Wenlock species, suggests that the limestone should be placed on a lower horizon than that of Lilydale, which contains a fauna with Devonian affinities. (2) The Stromatoporoids of the Buchan District, Victoria. Fourteen species and varieties are described, of which the following are new: *Actinostroma stellulatum* var. *distans*, var. nov., *A. contortum*, sp. nov., *Clathrodictyon convictum* var. *delicatula*, var. nov., *Hermatostroma episcopale* var. *buchanensis*, var. nov. The assemblages have, in the main, definite Devonian affinities, though typical Wenlock species, for example *Clathrodictyon regulare* (von Rosen), persist and make up a small proportion of the fauna.

G. Baker: Orthite in some Victorian granitic rocks. The study of the distribution of orthite in some granites and associated xenolithic rocks in Victoria indicates that orthite has a contamination mode of origin in most Victorian examples, and a pyrogenetic mode of origin in a few cases.

F. Chapman: Cherty Limestone with *Planorbis hardmani* Wade from the Mt. Elder Range, Kimberley District, W.A. The cherts were originally laid down in early Pleistocene times in shallow lakes on a peneplain, and are now perched on hills nearly 1,000 feet above sea-level. The Mollusca of the lake fauna comprise *Planorbis hardmani*, *P.* aff. *essingtonensis*, and a probable new species of *Bullinus*. Other indigenous organisms of this lake deposit are: calcareous algæ allied to *Cladophora* and *Charophytes*, freshwater sponge-spicules, Ostracoda and probable insect remains. There is also evidence that minute Foraminifera had been carried into this lake deposit by wind agency from the coast-line, the nearest point to which now lies about 160 miles to the north.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Tuesday, June 15

Eugenics Society, at 5.15—(at the Linnean Society, Burlington House, W.1).—Prof. W. G. Miller: "Veterinary Eugenics".*

Wednesday, June 16

Warburg Institute, at 5.30.—Dr. Otto Brendel: "Roman Emperor Worship" (succeeding lectures on June 23 and 30).*

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Woman Indexer at the Bureau of Chemical Abstracts, 46 Finsbury Square, E.C.2—The Secretary (June 15).

Teacher of Science and Teacher of Engineering in the Luton Technical College—The Director of Education, Shire Hall, Bedford (June 15).

Two District Forest Officers—The Secretary, Forestry Commissioner, 9 Savile Row, W.1 (June 16).

Assistant Lecturer in Mathematics in the University of Manchester—The Registrar (June 17).

Four University Demonstrators in Anatomy and One University Demonstrator in Physiology in the University of Cambridge—Dr. F. J. W. Roughton, Physiology Laboratory, Cambridge (June 18).

Curator at the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (June 21).

Lecturer in Mechanical Engineering in the Municipal Technical College, Hull—The Director of Education, Education Offices, Hull (June 21).

Lecturer in Physiology and Zoology in the Sunderland Technical College—The Director of Education, Education Offices, 15 John Street, Sunderland (June 22).

Assistant in Agricultural Botany in the Edinburgh and East of Scotland College of Agriculture—The Secretary (June 23).

Biochemist in the Royal Victoria Infirmary, Newcastle-upon-Tyne—Dr. Ungley (June 27).

Director of Research to the British Rubber Research Board—R.G.A., 19 Fenchurch Street, E.C.3 (June 30).

Foot-and-Mouth Disease*

THE Foot-and-Mouth Disease Research Committee of the Ministry of Agriculture and Fisheries was first appointed in 1924, and although it has not succeeded in discovering any method of prevention, and the policy of slaughtering all infected and contact animals still continues, it has found out a good deal about the virus and its reaction with the body. The present, fifth, progress report covers the work done in the last five years, mainly at the experimental station at Pirbright and also at the Lister Institute, and the National Institute of Medical Research at Hampstead.

The size of the virus has been more accurately determined by means of Elford's graded filter membranes. It is held up by all membranes with an average pore diameter of 25 mμ or less, whence the diameter of the virus particles is about 8–12 mμ, compared with a molecule of oxyhæmoglobin with a diameter of about 4 mμ. It is indeed about the smallest pathogenic virus known, and is actually smaller than some protein molecules such as hæmocyanin or those recently described by Stanley as causing tumours. Size measurements have also been useful in distinguishing the virus from the much larger agent which causes vesicular stomatitis in horses and cattle, a disease which has similar clinical symptoms. Attempts to cultivate the virus *in vitro* in the presence of guinea pig or calf tissue have been only very moderately successful, and, unlike many viruses, it will not grow at all in the developing egg of the fowl or duck.

One of the most obvious objects which the Committee must have had in view from the beginning is some sort of protective inoculation such as has been used so successfully for cattle plague. An attack of the disease confers an extremely solid resistance on a cow; but, as has been known for some time, there are several strains or sub-species of virus, and the recovered animal, unfortunately, is resistant only to that strain which caused its illness; it has, for example, been shown that an animal may be given three successive attacks by using three different strains, and it also follows that a cow which has survived a natural attack is by no means secure against picking up the disease again from another strain of virus. These embarrassing features are now known to be worse than was supposed, and recent work has shown a greater multiplicity of identifiable strains as well as the existence of a number which have uncertain characters; types hitherto unknown have appeared in Great Britain. Particularly inconvenient is the variation of infectivity for guinea pigs, since these are the standard animals used in testing for the presence of virus. Indeed, the prospect of finding an effective and practical method of immunization does not seem at all good.

A very interesting section of the report deals with the influence of diet on susceptibility, and it may surprise some of those who attribute so many ills to undernutrition to learn that well-fed, rapidly growing rats could be infected with a much smaller dose and took the disease much more severely than those which were fed on a meagre (but far from a starvation) diet. The animals which showed no symptoms after inoculation were in some instances found to be immune on subsequent testing after feeding up, showing that they had really been infected without any obvious illness; others, however, were susceptible, and in them presumably no infection at all had occurred.

---

* Ministry of Agriculture and Fisheries. Fifth Progress Report of the Foot-and-Mouth Disease Research Committee. Pp. 386+26 plates. (London: H.M. Stationery Office, 1937.) (7*s.* net.)

Good feeding, especially with such eclectic foods as liver and carrot, produces a high degree of susceptibility in a few days, and it takes a long time for the effect to wear off after the animals return to a more ordinary diet. Similar results were obtained with guinea pigs and hedgehogs, and they are no doubt analogous to the old observation of Arkwright that the inflammatory reactions following certain irritating stimuli are much diminished in underfed animals. It may well be that foot and-mouth disease was little obvious and did little harm among the scrawny cattle of past times in England, and it is just possible that some sort of vaccination with live virus might be a practical procedure if it was combined with deliberate underfeeding.

The major unsolved problem of the disease is, however, where the infection comes from and how it is spread. In the great majority of outbreaks, no perceptible source of infection can be identified, though for some time past they have been thoroughly examined by people fully alert to the various possibilities. With rare exceptions, each outbreak seems to be a thing of itself, and they are scattered about England in an apparently haphazard manner. Movements of cattle are, of course, continuously going on, and it has been suggested that some of them may be carriers of the virus without showing any signs of illness; the inquiries of the Committee do not, however, lend any support to this idea; nor do they favour the speculation that infection is brought from the Continent by birds, which are beyond the control of the most rigorous Ministry. With the dimming of what used to be the sharp boundary between live and dead, it is theoretically possible that the virus is frequently arising *de novo*, generated in cattle or pigs by some unknown influence. The great and apparently increasing variability of the virus is compatible with this idea, though it would be more orthodox to regard it merely as evidence that all the English outbreaks cannot have a common origin, or that the different sub-species of virus are not very permanent.

Spontaneous generation must, however, be the last resort of baffled epidemiologists, and the facts more reasonably suggest that infection is present in some common wild animal, very likely in a form which does not often cause any conspicuous mortality, as is often the case where an uncontrolled infection and its host come into some sort of permanent balance out of which, for reasons unknown, epidemics may arise. Of this line of thought the Committee has made a reconnaissance, partly by laboratory experiments, partly by trapping animals around the Pirbright Station, and partly by surveys of infected localities by Elton and his colleagues from Oxford. But it has all been on such a slight scale that it can scarcely be called an exploration, and much more work needs doing in the field, where it is none too easy under the conditions of isolation and disinfection which are imposed on infected farms.

Several animals and some birds are capable of being slightly infected by artificial inoculation, but the results are irregular and seem to be of no particular importance. The short-tailed field-vole (at any rate the northern form) is freely susceptible and the infection can be carried on in the laboratory from one animal to another by inoculation; it will not, however, spread from an infected to a healthy animal by contact any more than it will in guinea pigs, which implies that voles cannot be important in Nature from the point of view of infection.

The greatest suspicion attaches to the hedgehog, which by tradition is in the habit of sucking cows' teats and drinking the milk. This may or may not be true—the direct evidence for it is thin—and it may well mean nothing more than that it had been observed that close association between hedgehogs and cows was apt to result in a smaller yield of milk—an obvious symptom of foot-and-mouth disease. Whether they were confusing fact with interpretation or not, our ancestors certainly had such a dislike of the hedgehog as a harmful animal that, as Charles Oldham has shown, churchwardens in the eighteenth century would pay as much (fourpence) for an urchin as for a polecat. These bits of history make a rational tale if we suppose, with G. C. Damant, that the hedgehog is the natural reservoir of the disease. The Committee has shown that it is indeed very susceptible, and takes the disease severely: it is also the only wild animal known in which infection spreads from diseased to healthy animals by contact, and the virus has been demonstrated in the expired air. Moreover, in the small surveys which have been made, a single live hedgehog caught in the neighbourhood of an outbreak near Bristol was found to be infected, although it had no naked-eye signs of disease. At Pirbright a cow was infected by stall contact with a diseased hedgehog, and a hedgehog was infected by contact with a diseased cow. The case against the hedgehog seems strong enough to justify much more extensive and intensive field work.

Science and John Donne

John Donne and the New Philosophy
By Prof. Charles Monroe Coffin. Pp. ix+311. (New York: Columbia University Press; London: Oxford University Press, 1937.) 17*s.* 6*d.* net.

THE author explains in his preface that, while this book was undertaken as an "academic exercise", it fulfils a long-standing desire dating from a time many years earlier when he fell under the spell of Donne's poetry and noticed that none of the numerous and worthy studies of his life and works which have appeared in recent years seemed to touch more than lightly on the subject of his response to the new philosophy; whereas he (the author) conceived the idea that in Donne's familiarity with the "new science" there might be found an explanation of the compelling interest he has had for the late nineteenth and the twentieth centuries. He wished, therefore, by this study to provide a necessary supplement to such books as "The Life and Letters of John Donne", by Edmund Gosse (1899), and the prefaces, introductions and notes to the editions of his poems by Charles E. Norton (1895), E. K. Chambers (1896), and Prof. Herbert J. C. Grierson (1912), as well as "A Study of the Prose Works of John Donne" by Mrs. Evelyn M. Simpson (1924). Professor Grierson had already remarked that "No other poet of the seventeenth century known to me shows the same sensitiveness to the consequences of the new discoveries of traveller, astronomer, physiologist and physician as Donne"; and Mrs. Simpson clearly saw that, as a result of the influence upon Donne of the beginnings of modern science, "the break up of a whole system of thought is reflected in his pages".

Donne was brought up as a Catholic, and was first educated abroad by the Jesuits, who were governed by the Ptolemaic-Aristotelian system as brought by St. Thomas Aquinas into harmony with Christian doctrine. While his instruction by the Jesuits stimulated his interest in many branches of learning, Donne's independent and even heretical spirit chafed under their authoritarian régime. In 1584 he entered Hart Hall, at Oxford, "that refuge for adherents of the old religion", which again meant a curriculum of study scarcely less medieval than that followed by his Jesuit instructors. In 1586, or soon after, he is said to have gone to Cambridge, where the Reformation had taken stronger hold, and the contest was then not so much between Catholic and Protestant as between the National Church and the dissenters. Moreover, rebellion against the medieval scholasticism had been encouraged there by Francis Bacon's denunciation of the too dominant influence of Aristotle at the University, and more specifically by the publication by the Cambridge University Press of an edition of the "Dialecta" of Peter Ramus (Pierre de La Ramée) challenging the whole of Aristotle's logic.

Cambridge had also produced before Donne's time the first champions of the new science of the Renaissance. Among these were Robert Recorde, the author of "The Grounde of Artes", and John Dee, who were both adherents of Copernicus, as well as Thomas Digges (son of the mathematician Leonard Digges), who had (before 1576) made the first English translation of Copernicus and had prepared a map of the heavens according to the new system. Henry Briggs, later Savilian professor of geometry at Oxford, was made fellow of St. John's College in 1588 and was still at Cambridge while Donne was at the University

Donne belonged, however, to no school and was a disciple of no system; he was greedy of learning and experience of all sorts, regardless of consequences; he speaks himself of his "hydroptique immoderate desire of humane learning." He was most deeply impressed by two things: (1) the refutation of Aristotle's dictum about astronomy (that the heavens are unalterable because in so many ages nothing had been observed to have been altered, "De caelo", i. 3), by the discovery of new stars, and (2) the deposition of the earth from its place in the centre. On the second point we know that Donne was familiar with the Copernican hypothesis before (in 1611) he brought out "Ignatius his Conclave", which not only introduces Copernicus as one of the characters but also mentions Kepler and Galileo, and shows that Donne was versed in the earlier history of the subject and the parts in it attributed to Ecphantus, Heraclides and Aristarchus of Samos. Allusions in the poems are illustrated by the lines in "The First Anniversary" (1610-11), "The sun is lost and th' earth, and no man's wit Can well direct him where to find it", where by "lost" applied to the sun he means lost in the sense of a beneficent satellite as it were. (Incidentally, it is worth noting that Robert Burton, a contemporary of Donne, wrote in "The Anatomy of Melancholy": "Copernicus, Atlas his successor, is of opinion the earth is a planet, moves and shines to others as the moon doth to us. Digges, Gilbert, Keplerus, Origanus, and others defend this hypothesis of his in sober sadness, and that the moon is inhabited: if it be so that the earth is a moon, then are we also giddy, vertiginous and lunatic within this sub-lunary maze".)

As regards new stars, Donne shows by a marginal note to "Biathanatos" one source of his information, Kepler's "De stella nova" (1606) containing an account of his discovery in 1604 of a brilliant new star in the constellation of Serpentarius. He was acquainted too with Galileo's "Sidereus Nuncius" (1610), the full title of which is, in translation, as follows: "The Astronomical Messenger, containing and setting forth Observations lately made with the aid of a newly invented Telescope respecting the Moon's Surface, the Milky Way, Nebulous Stars, an innumerable multitude of Fixed Stars, also respecting Four Planets never before seen which have been named the Cosmian Stars". The planets mentioned were the four satellites of Jupiter, discovered by Galileo, and are plainly alluded to in "The First Anniversary", "And freely men confesse that this world's spent when in the Planets and the Firmament they seeke so many new . . ." One more quotation from "The First Anniversary" may be permitted, "And now Philosophy calls all in doubt, The Element of fire is quite put out". Cardan had denied the existence of the element of fire ("De subtilitate", which Donne had mentioned in "Biathanatos"), but it was more probably from Kepler ("Dioptrice") that he learnt of the "confutation" of fire by Tycho Brahe and Pena, and by Kepler himself

The book contains fifteen chapters, of which the following may be mentioned: Poetry and Science (i), The Old Order (iii), The Rise of the new Philosophy (v), The Moving of the Center (vi), The New Heavens (vii), "Figures of Space (ix), The Text Saves Us (xi), in which the editor shows the scholarly habits of Donne, how he searched for ultimate sources, compared texts to test their relative validity, acknowledged his obligations to those who had supplied him with information, and even indulged in footnotes.

Enthusiasts for Donne will find the book a mine of detailed and accurate information about his works and thought; while all who are interested in the history of astronomy will, in the text and the elaborate notes, find many particulars about the original works of Copernicus, Kepler and Galileo, as well as many facts in the history of astronomy (especially that of the Greek pioneers).

Morphogenetic Factors of Bone

Bones:
a Study of the Development and Structure of the Vertebrate Skeleton. By Dr. P. D. F. Murray. Pp. x+203+8 plates. (Cambridge: At the University Press, 1936.) 8*s.* 6*d.* net.

THE study of the factors which determine the growth and form of an organism is the special province of the morphologist. Hitherto this has been mainly pursued by the investigation of the biological history of the organism or structure, and indeed morphology has become more or less synonymous with the historical approach. The other common factor, the influence of function upon structure, has of course been implicit in all sorts of biological studies. Beyond these historical or functional investigations of the determinants of form, there is still the experimental approach to the question of the relation between the structure made visible by anatomical methods and the morphogenetic factors that have brought the structure to the state which has actually been achieved.

It is the especial merit of the Strangeways Laboratory at Cambridge, over which Dr. H. B. Fell presides, that it has become one of the most distinguished places in the scientific world for the prosecution of morphogenetic studies. Here the technical methods, tissue cultivation *in vitro*, tissue grafting, the growth of large explants under a variety of conditions, embryological experimentation, the registration of results by the Canti cinema method and so on have been used abundantly, and, in the process, made more efficient and applicable on a wider scale. Dr. Fell and the Strangeways Laboratory have placed British anatomists deeply in their debt.

The present volume relates the work done there by Dr. Murray and his colleagues as it bears upon the anatomical problems presented by bone. The author has set himself the task of presenting the knowledge available which throws light on the factors determining the position of bone. For example, in the membranous skull of the embryo it may be inquired why the sutural margins run where they do. As a matter of experimental observation, the position of the bone and the limiting sutural lines seem inherent in the cells of the dura mater, for when bone including the sutural line is removed and the dura is left intact, both the bone and the sutural line in its normal position are regenerated. Next the author discusses the differentiation of the architectural structure of developing and adult bone. It has become almost traditional in anatomical schools to regard this as a precise orthogonal pattern precipitated as it were along the lines of tension and compression. The matter is not nearly so simple, and much further investigation is necessary upon this problem.

The fixing of the form of the bone is perhaps an issue upon which the most spectacular experiments have been performed by Dr. Fell and her colleagues. The growth of a recognizable femur outside the body beginning from its primordial mesenchymatous stage was a great achievement and also prepared one to believe in the potency of the factors inherent in the primordial cells. In later life, however, extrinsic factors have more say in influencing shape than in these earliest stages. Finally, of course, there is the problem of how increase in size is attained with the preservation of the characteristic form of the bone. This problem in bone growth has been long investigated, and Dr. Murray mentions that it is germane to his theme. He omits it, however, from his book in order that he may write more particularly upon the experimental aspect of the other two problems mentioned. The problems raised cover all the bones of the skeleton, and a special chapter is given to cartilage.

Those who study the morphogenetic factors cannot help being impressed by the inherent formative properties of the cells themselves. It is difficult to refrain from endowing them with potentialities that make further scientific investigation impossible. The cure for this seems to be more experiments, for some of the supposed facts which have been the starting point of theories outside the realm of science have been shown later to depend on interpretations which further investigation has proved to be erroneous. Dr. Murray has refrained from any such speculation, and has given us a straightforward account of the problems, the experiments and the results obtained. In thanking the author one may append a remark upon his concluding sentence. The author modestly suggests that his book at least has the merit of raising more problems than it solves; the commentator may justly add that it has the merit of raising them in a form that at least makes solution seem not impossible.

Infectious Exanthemata

The History of the Acute Exanthemata: the Fitzpatrick Lectures for 1935 and 1936, delivered before the Royal College of Physicians of London. By Dr. J. D. Rolleston. Pp. ix + 114 + 10 plates. (London: William Heinemann (Medical Books), Ltd., 1937.) 7*s*. 6*d*. net.

THIS small volume contains the Fitzpatrick Lectures for 1935 and 1936. It is concerned with the history of smallpox, chicken-pox, scarlet fever, measles and German measles.

The study of the history of *diseases* presents special difficulties, and in the case of the infectious exanthemata these difficulties are accentuated by the fact that "it is now generally agreed among medical historians that the acute exanthemata were not distinguished from one another until a comparatively late period of their history". This point is exemplified in many passages. "In spite of the teaching of Heberden, Cullen, Willan, and others, there were not lacking during the nineteenth century writers, including some of high distinction, who maintained the identity of smallpox and chicken-pox". "Richard Morton held the view that scarlet fever was exactly the same as measles." The problems which confront the medical historian are much increased by such diagnostic confusion.

Even more perplexing is the nomenclature. Both German measles and chicken-pox received a multitude of names, out of all proportion to their real significance. Chicken-pox, first described by Ingrassias in 1552 under the name of crystalli, has been rechristened forty times; whilst German measles has at least a dozen names. The author negotiates all such obstacles with a confidence which can only come from practical experience and a wide knowledge of the literature of each disease. He goes further, and makes his subject one of profound interest to the reader.

The importance of medical history as a guide to modern practice is apt to be overlooked. Here, the reader finds no excuse for such neglect. Many a modern 'discovery' has its roots in the distant past. Athanasius Kircher (1601–1680) examined the pus of smallpox lesions, and attributed the disease to the action of micro-organisms. Boerhaave (1668–1773) maintained that smallpox was a specific disease spread by contagion. In the middle of the eighteenth century, Francis Home (1719–1813) anticipated the modern prophylactic use of convalescent serum in measles, by using infective blood as an application to the scarified skin.

History also emphasizes the danger of introducing the acute exanthemata to a virgin soil. One of the earliest examples of this kind is the Amazon measles epidemic of 1749, when 30,000 natives died of this disease. In 1846 a somewhat similar fate befell the Faroe Islands, and in 1875 Fiji, when nearly a quarter of the population died of measles. The lesson was brought home to Great Britain in 1914–15, when a Highland Division in training at Bedford had 529 cases with 65 deaths.

Another example of the value of history in actual practice is found in the variability of virulence in epidemics. One example out of the many provided will serve as an illustration. It refers to the experience of Bretonneau at Tours with regard to scarlet fever. During the period 1799–1822, he never saw a single death from this disease, which he always found a very mild complaint. In 1824 an epidemic occurred which proved so deadly and refractory to treatment that he came to regard scarlet fever as formidable a disease as plague.

The value of the work is enhanced by a generous list of references, also a series of portraits of those who have contributed to our knowledge on the acute exanthemata. A book which may be recommended to all who are interested in the history of medicine.

Fundamental Electrical Measurements

Electrical Measurements:
Precise Comparisons of Standards and Absolute Determinations of the Units. By Dr. Harvey L. Curtis. (International Series in Physics.) Pp. xiv + 302. (New York and London: McGraw-Hill Book Co. Inc., 1937.) 24*s*.

THERE can be but few physicists better entitled than Dr. H. L. Curtis to write on fundamental electrical measurements. As an associate of Rosa, Dr. Curtis has witnessed the development of high-precision work on electric units at the National Bureau of Standards, Washington, and since then he has never ceased to improve existing methods, and to devise new methods in an effort—and a successful one—to increase the accuracy of determination of electric units.

The first quarter of the book under notice treats of units and standards generally. The descriptions of the most modern types of manganin wire resistance standards and of cadmium standard cells are particularly useful, as are also the details of the methods by which national laboratories maintain their units of resistance and of electromotive force.

The comparison of standards is dealt with next. In this section, as elsewhere, instead of outlining all the accurate methods available, the author selects one or two methods, possibly those with which he is most familiar, and describes them in detail. Among the measurements involving two or more electrical quantities, the determination of capacitance by the Maxwell bridge, in terms of resistance and time, receives very good treatment.

The second half of the work is devoted to calculation and design of inductance, and absolute measurement of resistance and current. It is no simple matter to deal with the computation of self and mutual inductance in a few pages, but Dr. Curtis has performed his task remarkably well; rightly starting from first principles, he introduces the reader without difficulty to the complicated formulæ which represent the solution of practical problems. The next chapter, nominally concerned with design of standards of inductance, is devoted mainly to a description of a particular method of winding a solenoid on a cylindrical former. In this chapter and elsewhere in the course of the work, the author embarks on the risky venture of suggesting, and even describing in detail, methods of procedure which have never been subjected to serious test. In this case, the suggestion refers to the construction of a mutual inductor from two solenoids.

Absolute measurement of resistance comes next. A survey of old and new methods is followed by very complete descriptions of the Lorenz method and of the self-inductance bridge method. In the same way the absolute measurement of current is illustrated by detailed descriptions of the Rayleigh balance, for the improvement of which Dr. Curtis is himself largely responsible, and of the Ayrton-Jones balance of the National Physical Laboratory.

The comparative definitions of units in the electrostatic and electromagnetic systems, given in the second chapter, could easily have been avoided by the use of the M.K.S. system of units recommended by the International Electrotechnical Commission. Automatically, the last chapter would then have received a simpler title, and it is possible that with ideas clarified by a more logical choice of starting-point, Dr. Curtis would not have written (top of p. 219): "the variability of the earth's magnetic field prevents its accurate measurement *in c.g.s. units*".

Printing and diagrams are excellent.

British Trees and Shrubs, including those commonly planted:

a Systematic Introduction to our Conifers and Woody Dicotyledons. By H. Gilbert-Carter. Pp. xv+291. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 12*s.* 6*d.* net.

Dr. Gilbert-Carter's aim in writing this sequel to his earlier "Catkin-Bearing Plants" is threefold: to enable students to identify our native woody plants, and many commonly cultivated ones; to illustrate Engler's system of classification and to show, by giving the derivations of all the Latin names used, that botanical nomenclature is a human subject with its roots in the past.

The descriptive treatment of the various groups is, on the whole, excellent, though some of the specific descriptions are too brief for certain identification. Under many genera and species valuable notes are given on distribution, ecological preferences, medicinal and culinary virtues, cultivation and general biology. Readers will very rarely have to rest content with the name of any specimen they identify; some illuminating sidelight is nearly always thrown on one or other aspect of the species concerned.

In his preface, and under many of the classes, groups, orders and families, the author discusses briefly the theory and application of Engler's system of classification. He is sceptical, as was Engler, of the possibility of making phylogenetic speculation the basis of natural classification, and uses throughout the noncommittal term 'affinity' when discussing relationship. Dr. Gilbert-Carter's remarks are a welcome contribution to a subject on which many taxonomists are by no means clear.

The footnotes giving the derivation and pronunciation of Latin names will be appreciated by all who value the historical approach, and are not content merely to repeat, parrot-like, the names that they are taught. The few inaccuracies that have crept into these admirable notes will doubtless be corrected in a future edition.
J. S. L. G.

Hardy Californians

By Lester Rowntree. Pp. xv+255+64 plates. (New York: The Macmillan Co., 1936.) 18*s.* net.

The title of this book may call up visions of the "Old Timers" or "Redskins" of the novelist or of Hollywood, but in fact it deals principally with the hundreds of little-known, but none the less interesting and beautiful flowers of the amazing western State, California.

Mrs. Lester Rowntree takes us with her in her travels from what she calls the "Top of the World", altitudes of 9,000–14,000 ft., down to "Death Valley" 276 ft. below sea-level, and from the heat and glare of the Colorado Desert to the dense shade and humidity of the Redwood Forest; a revelation of the wide range of geographical conditions existing in that State. To the Nature lover or gardener, the book is as thrilling as any Western romance, for it is an introduction on an intimate and personal footing to the "plant personalities" she loves and describes so well.

The wealth of detail given on soils and situations, possible requirements in cultivation, etc., is of course intended to assist the gardener, but it is none the less interesting to the botanically minded, and particularly to the student of ecology. To some of the genera with which we in Britain have a nodding acquaintance, for example, *Penstemon*, *Lupinus* and *Viola*, the author devotes whole chapters, and one chapter is reserved for the wonderful and varied range of bulbous plants for which the West is famed. How many of the plants enumerated will prove hardy in Great Britain is an open question, for the book is written primarily for American gardeners and climatic conditions. A fair proportion will undoubtedly find congenial homes in Great Britain, for where else will they receive such hospitality or obtain climatic conditions so varied ?
G. W. Robinson.

Electrical Engineers' Handbook

(Vols. 4 and 5 of Wiley Engineering Handbook Series.) 4: Electric Power. Prepared by a Staff of Specialists under the Editorship of Dr. Harold Pender, William A. Del Mar, Knox McIlwain. Third edition rewritten. Pp. xiv+1268+37. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 30*s.* net.

Electrical engineers' handbooks have become both bulky and inconvenient, and contain much duplicated matter owing to the rapid development of the various branches of engineering. In this series it has been decided to publish the fundamental material which forms the basis of all engineering in a separate volume, and the existing handbooks as they are revised are being issued in several volumes containing material closely connected with the specialized branch considered. The entire new series of handbooks will give much more complete information on all topics of interest to engineers.

The latest developments of filament and discharge lamps, methods of air-conditioning, and ventilation fans are all described and the physical constants of building materials including their thermal conductivities are discussed. To the practical engineer, this book will be useful for reference. The latest information about electric power has been included.

The Cactus Eaters

By Julian A. Weston. Pp. 240+16 plates. (London: H. F. and G. Witherby, Ltd., 1937.) 10*s.* 6*d.* net.

In "The Cactus Eaters" the author records the results of a stay of four months on the Goajira Peninsula on the southern shore of the Caribbean Sea and a boundary area between Colombia and Venezuela. His purpose was to observe the customs and culture of the Goajiro Indians. Although a stock-raising people, it is evident that in level of culture they have advanced little beyond the hunting stage, and the author discusses the interesting question of the nature of their subsistence in pre-Conquest days, as their stock must have been derived from the Spaniard. In view of environmental conditions and cultural indications, it is suggested that they may have been a people of a fishing culture.

A Taxonomic Problem

By J. S. L. Gilmour

AMONG present-day biologists there is widespread interest in, and considerable disagreement on, the proper relationship between taxonomy[*] and other branches of their science, especially genetics, cytology and ecology. Should the data provided by these branches be incorporated into the existing taxonomic categories, or should new categories be created to meet their needs ?

In discussing these questions, I believe that the purpose and general principles underlying the process of classification have been unduly neglected and that a consideration of these would help materially to clarify the issues involved. A full discussion of these principles may be found in the standard works on logic and scientific method[†], and only those points most relevant to the present problem will be dealt with here.

In its simplest terms, classification consists in grouping individual objects (and, ultimately, sense data, expressed as qualities and relations) into classes, so that all the individuals in one class have certain attributes in common. The use of such general names as book, piano, mountain, etc., involves a process of classification no less than the formation of such classes as mammals or flowering plants. Viewed thus, classification is seen to be a necessary stage in the inductive process by which the human mind obtains an ordered knowledge of the universe. Ritchie (*op. cit.*, p. 79) has expressed this concept of classification as follows : ". . . our general knowledge of the external world as expressed by laws of nature is a product of the interaction of two processes, selection from and classification of what is experienced and the discovery of laws relating to the classes".

Any given collection of objects can, of course, be classified in a great number of different ways, depending on the particular attributes chosen as a basis for classification. Thus mankind can be classified on a basis of nationality into Frenchmen, Germans, etc. ; on a basis of occupation into lawyers, doctors, etc. ; on a basis of physical characters into the various so-called 'races', and so on. Further, the choice of particular attributes depends on the *purpose* in view in making the classification. Thus if we wish to investigate the distribution of professions among the inhabitants of different countries, we employ classifications based on the attributes of occupation and nationality, and, from an examination of the resulting classes, we formulate laws relating them, such as, for example, that there is a greater proportion of clergymen in England than in the U.S.S.R.

These considerations apply also to biological classification in general. Fundamentally, the purpose of biological classification is the acquisition of ordered knowledge regarding living things, and logically any grouping of plants and animals should be considered a taxonomic process. Such groups as hydrophytes, succulents, hemicryptophytes, ruderals and alpines are, in this sense, 'taxonomic' groups, no less than the families, genera, species, etc., of 'traditional' systematic botany. Why is it, then, that the term taxonomy is usually confined to this latter grouping ? Why are Ranunculaceæ, but not annuals, considered a taxonomic group ? The answer to this question involves a consideration of the difference between a natural and an artificial system of classification.

The term 'natural classification' is a general one, the significance of which is not confined to the grouping of living things. It is usually stated in logic that a system of classification is the more natural the more propositions there are that can be made regarding its constituent classes. For example, a classification of mankind on a basis of nationality is more natural than one based on the initial letter of surnames, because more propositions can be made regarding an Englishman (for example, that he probably speaks English, knows "God Save the King", has a white skin, etc.) than about a man whose name begins with E. Thus a natural classification is one founded on attributes which have a number of other attributes correlated with them, while in an artificial classification such correlation is reduced to a minimum. From the point of view of function, a natural classification can be used for a great variety of purposes, while an artificial one serves only the limited purpose for which it was constructed.

The difference between them can be expressed in another way. The greater number of propositions that can be made regarding an Englishman depends on the fact that nationality (the basis of the classification) is an attribute connected with a very important factor in human life (namely, the habit of living in territorial groups to which we become emotionally attached), while the initial letter of surnames is not. This point is made clearer if we imagine that a dictator has decided to execute forthwith all those whose names begin with E. This attribute would then become connected with another important factor in human life (namely, the power of a dictator) and immediately the hitherto artificial group of E's would become, at any rate temporarily, a natural one, about which many propositions could be made (for example, that they would soon be dead, were probably frightened, were probably making their wills, etc.). From this rather trivial example, the proposition emerges that a natural classification is one which is based on attributes connected with a factor that has an important influence on the objects being classified: the more important the factor the more natural the classification becomes.

---

[*] "Taxonomy" is here understood in its ordinary dictionary definition of "the principles and practice of the classification of living things". The discussion concerns taxonomy in general, though I have had chiefly in mind the higher plants. I am grateful for certain suggestions made by those who have been kind enough to read through the paper.

[†] See especially : "Logic" by J. S. Mill (1843) ; "Logic" by A. Bain (1878) ; "The Principles of Science", by W. S. Jevons (1883) ; "Logic", by Carveth Read (1898) ; "The English Utilitarians", by L. Stephen, Vol. III (1900, esp. pp. 124–131) ; "The Use of Words in Reasoning", by A. Sidgwick (1901) ; "Inductive Logic", by T. Fowler (1904) ; "Formal Logic", by F. C. S. Schiller (1912) ; "A New Logic", by C. Mercier (1912) ; "The Philosophy of Biology', by J. Johnstone (1914) ; "Scientific Method", by A. D. Ritchie (1923) ; "Biological Principles", by J. H. Woodger (1929) ; "Modern Introduction to Logic", by L. S. Stebbing (1930).

The difference between the two is therefore one of degree only. Indeed, it is impossible to construct a classification that is not to some extent natural. As pointed out by Jevons (*op. cit.*, p. 680), even in so artificial a class as those whose names begin with E, there will probably be an abnormally high proportion of Welshman owing to the presence of a large number of Evanses.

If there is one factor influencing a particular collection of objects which is more powerful than any other, then a classification based on attributes connected with that factor will be more natural than any other. For example, in classifying a number of motor-cars which were manufactured during the last forty years, the most natural classification would be a division based on attributes connected with the period of manufacture, because that is the most important factor determining the attributes of the cars. If, however, there are several factors of nearly equal importance influencing a group of objects, then a number of equally natural classifications is possible. This is the case in the classification of mankind, where, for example, it is difficult to say whether a basis of nationality or annual income gives a more natural classification.

If these conclusions are applied to biological classification as a whole, the reason for the unique position held by traditional taxonomy begins to emerge.

Owing to the method of reproduction and evolution of living things, involving the inheritance of parental characteristics, and to the pre-eminent influence that these factors exert on the attributes of plants and animals, the possibility exists of constructing a series of classifications which are more natural than any others, namely, those based on inherited characters. It is by a constant search for the most natural among these classifications that the present vast structure of traditional taxonomy has been gradually built up. We may say, then, that the unique position held by traditional taxonomy, marking it off from other arrangement of living things, is primarily due to the possibility of constructing a set of peculiarly natural classifications of living things based on inherited attributes.

On this view, a natural classification in biology is a particular example of natural classification in general and not a phenomenon peculiar to living things; further, a natural classification differs in degree only from other biological classifications. This is in contrast to the concept, widely (though not universally) accepted in post-Darwinian times, of a natural classification as being based on *actual phylogenetic relationship* and thus differing fundamentally from artificial classifications. This view involves the assumption that there exists a criterion of degree of phylogenetic relationship, apart from degree of similarity of attributes, and either that such a criterion should be used in constructing a natural classification, or that degree of similarity of attributes is an invariable indication of such relationship and can therefore be used as a basis for a natural classification.

Now, this criterion of phylogenetic relationship must presumably be the same that leads us to say that two brothers are more nearly related than two cousins—namely, the degree of remoteness of a common ancestor. But in order to judge degree of relationship on this criterion, a knowledge of the genealogy of every *individual* in any group under consideration is essential, and such knowledge, except occasionally in man and in certain domesticated animals and plants, is clearly unobtainable.

Can we, then, fall back on the second alternative and accept degree of similarity of attributes as an invariable indication of degree of relationship? That such similarity is frequently an indication of relationship is true, but that it is an invariable indication certainly cannot be maintained. For example, two individuals related as cousins may have identical genotypic constitutions, while two sibs may be strikingly different and, further, parallel mutations may occur in two individuals only distantly related phylogenetically but of similar genotypic constitution.

If, then, the criterion of degree of relationship applicable to *individuals* cannot be applied in practice to *groups*, and, further, if similarity of attributes cannot be regarded as a certain indication of such relationship, then it would seem that the view that a natural classification differs fundamentally from artificial classifications in that it represents phylogenetic relationship cannot be substantiated. A natural classification should rather be regarded, first and foremost, as that arrangement of living things which enables the greatest number of inductive statements to be made regarding its constituent groups, and which is therefore the most generally useful classification for the investigation of living things. Whether or not such a classification does in fact group together individuals who are phylogenetically related is a secondary question which must be answered for any particular case on its merits.

For special purposes, however, additional classifications are essential. As emphasized above, classification is a stage in inductive investigation, and in so far as it is desired to discover laws relating certain attributes of living things, such attributes must be embodied in distinct classifications of greater or less complexity. The need for such additional classifications is obvious when the attributes concerned give an arrangement conspicuously less natural than that of traditional taxonomy, for example, a classification into trees, shrubs, herbs, etc., or on medicinal properties. But when the classification is only slightly less natural than the most natural possible, then its validity becomes obscured and confusion arises between it and traditional taxonomy. Such is the case with many of the attributes that have been investigated during the last thirty or forty years under the headings genetics, cytology, physiology and ecology. For example, a traditional taxonomist may divide a genus into a certain number of species on morphological characters, the result being a good natural grouping. A cytologist may then investigate the same genus and find that, say, sterility barriers in some cases cut right across the taxonomist's groups. If the sterility classification is the less natural of the two, that is, if its groups show a smaller correlation of attributes, it should not, as is sometimes suggested, be dismissed as 'taxonomically useless'; but should be retained as a distinct classification for the purpose of establishing the relationship between sterility and other attributes.

This principle of 'multiple classification' is fundamental to the proper functioning of taxonomy as an instrument for the inductive investigation of living things. How can it be most satisfactorily applied in the present position of biological taxonomy? A few tentative suggestions may be put forward.

The categories and nomenclature of traditional taxonomy should be confined to the most natural classification possible in the existing state of knowledge of any particular group, on whatever attributes it may be based, and such a classification would be the most generally useful for a great variety of purposes, both scientific and non-scientific.

Any exact definitions of the categories within this classification are, in my opinion, an impossibility. The categories, genus, species, etc., are of the same nature as such categories as herd or heap, individual *characters* taking the place of individual animals or stones. A well-known trick in logic known as the 'sorites' illustrates this point. The question is put "Does one stone form a heap?" If the respondent answer "No", it is asked, "Do two stones form a heap?" and so on. Great difficulty is found in deciding when the addition of one stone constitutes a heap. The answer would vary from person to person and also according to the shape and size of the stones. Similarly, in a natural classification, the definition of the categories must vary somewhat according to the mentality of individual biologists and the nature of the material being classified.

If the traditional taxonomy is defined in this way, what should be the aim and methods of the additional classifications necessary for special investigations? Unlike the classification of traditional taxonomy, they should be based on the same attributes throughout, and their categories should have a different terminology from that of traditional taxonomy. A good example of such a system is Danser's classification into commiscuum, comparium and convivium, which is based purely on interfertility criteria[1].

Many other classifications based on data provided by genetics, cytology and ecology have been proposed during this century[2], but these have for the most part either redefined the categories of traditional taxonomy in such a way as to destroy their general usefulness, or have employed mixed attributes as a basis for new categories. It is greatly to be desired that agreement should be reached on the employment of other classifications similar to Danser's (either new ones, or existing ones modified where necessary), based on other attributes. The number and complexity of such classifications are, of course, questions of meeting the ever-changing needs of biological investigation, and no limits either way can be set.

With regard to nomenclatural technique, it would seem possible that, where necessary, the method of employing Latin words with a prefix or suffix to distinguish them from the Latin names of genera, species, etc., which has already been used with success, for example, for the ecological categories of association, etc., might be extended to classifications based on other attributes.

The Hammond Electric Organ

THE development of the loud-speaker, and more especially the demonstration of its capability of reproducing all types of music in connexion with the projection of the talking film in the cinemas, has suggested to a number of inventors the possibility of the replacement of the ordinary pipe organ by one which is entirely electric. Many patents have been taken out both in Great Britain and abroad, some utilizing electrically recorded wave forms and a photo-electric cell, and others building up the tone quality from combinations of sine waves; for it is well known that any periodic wave can be analysed into a series of sine waves of which the frequencies are multiples of that of the original wave. Of the latter, the two most successful are that of the Compton Organ Co., in which the waves are generated by a variable capacity, and the Hammond organ.

In the Hammond organ the currents are produced electromagnetically by rotating an iron disk *D* (Fig. 1), about the size of a half-crown, with a serrated edge, in front of the end of a permanent magnet *M* on which is a coil of wire *B*. The change of flux through the coil, caused by the variation of the gap between the serrated edge of the disk and the end of the magnet, produces an alternating E.M.F. in the coil; the edge of the disk and the pole of the magnet are so shaped that this E.M.F. shall follow a sine curve as closely as possible. There are twelve of these disks, each with its own magnet and bobbin of wire, to each octave. The disks of one octave are all mounted on a single shaft and rotate as a whole. The shafts and disks of the successive octaves are all similar and are so geared together that the shaft of each octave shall run at twice the speed of the preceding one.

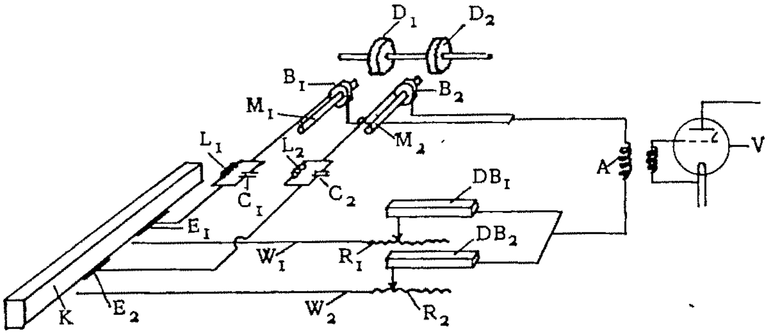

Fig. 1.

DIAGRAM OF ACTION OF THE HAMMOND ORGAN: *A*, COIL; B_1, B_2, BOBBINS; C_1, C_2, CAPACITIES; D_1, D_2, DISKS; DB_1, DB_2, DRAWBARS; E_1, E_2, CONTACTS; *K*, KEY; L_1, L_2, INDUCTANCES; M_1, M_2, MAGNETS; R_1, R_2, RESISTANCES; *V*, VALVE; W_1, W_2, WIRES.

The number of serrations on the edges of the twelve disks of one of these octaves has to increase progressively so as to give as approximately as possible the notes of the equitempered scale. The number of turns on the bobbins is reduced in the successive octaves to compensate for the increased flux due to the increased speed of rotation, and by this as well as by adjusting the distance of the magnets from the edges of the disks, the intensities of the notes produced are equalized throughout the whole range of the circuits, of which there are ninety-one in all.

There are two keyboards, each with five octaves. To combine the sine waves produced by the rotations of the disks in order to give the organ tones required, each note *K* (Fig. 1) on the keyboard can be connected to nine harmonically related bobbins, and the intensity of each of these circuits can be varied at will. For example, middle C can be connected not only to the bobbin giving the note of middle C, but also to the bobbins giving the fourth and the octave below (G_1 and C_1) and to those giving the octave above, the twelfth, the second octave, seventeenth, nineteenth, and third octave (C′, G′, C″, E″, G″, C‴.) These connexions are made by means of insulated contacts *E* under the keys, one connected to each bobbin, which are brought down, when the key is depressed, on to nine wires *W* stretching from side to side of the keyboard. The nine wires go to a group of nine draw-bars *DB* situated over the keyboard, each of which can be set at nine positions numbered from zero to eight. All the ninety-one circuits have initially the same resistances, and the draw-bars insert a resistance *R* which varies from infinity to nothing as they are drawn out, and thus each draw-bar adds a determined amount of the corresponding harmonic according to the position at which it is set.

To prevent the current from one bobbin feeding back through a key and the draw-bars to another bobbin and so giving false notes, there is a tuned circuit, consisting of a capacity and an inductance in parallel, between each bobbin and the keyboard.

Thus the complete circuit starting from the bobbin passes first through the tuned circuit, then branches and goes to the nine keys connected to that bobbin. Then it goes through the wires stretched across the keyboard to the nine drawbars and through their resistances. These resistances are all joined together and the combined current now goes to a coil *A* which may be considered to be similar to the aerial coil of a wireless set, and from that back to the bobbins. The current is now amplified in the usual way and after a second amplification by another valve it passes to a variable resistance controlled by the swell pedal; this swell effects an enormous change in intensity, amounting to a variation of some fifty decibels as compared with about thirty at most of the ordinary organ. It, in fact, is equivalent to the drawing of extra stops in an ordinary organ in addition to the increase produced by the opening of the swell box. From the swell pedal resistance the current is taken by a cable to the power cabinet, where it is amplified by a further range of valves and feeds the loud-speakers; of which there may be two or four or more according to the size of the building for which the organ is required.

Fig. 2

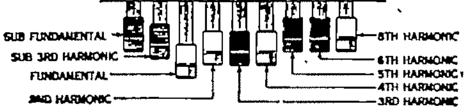

Fig. 3

As already mentioned, there are two five-octave keyboards (see Fig. 2). Above the keyboards there are four groups of harmonic draw-bars, nine bars to each group; the two left groups are for the upper keyboard and the two on the right for the lower keyboard. One of these groups is shown in Fig. 3. Between these in the middle are two harmonic controllers for the pedals. To the left of the five octaves of playing keys is another group of keys looking like the playing keys except that their colours are reversed. These correspond to the piston buttons in an ordinary organ, and eighteen of them give various combinations of tones which imitate very closely the types of combinations that are obtained on an ordinary organ—the diapasons, the reeds, diapasons and reeds, full organ, certain solo stops, etc.—pressing down one of these keys brings that quality of tone into action, at the same time cancelling the last combination used. Two of the keys bring one or other of the two groups of drawbars over the keyboard into action; thus the player can change from one of these groups to the other instantly, or to any one of the nine pre-set combinations, merely by pressing the appropriate key. The great variation in power of 50 decibels given by the swell pedal makes each of these pre-set combinations equivalent to a large number of organ stops.

To indicate the use of the drawbars a few tone colours as given by the makers are set out below. The numbers indicate the extent to which the bars are drawn (third from left is the fundamental).

007,755,220	Open diapason.
012,221,300	Soft strings.
145,645,553	Full swell.
015,656,342	Diapason chorus with mixtures.
006,470,520	Clarinet.
677,778,677	Full organ.

It is obvious that an almost infinite number of combinations of these harmonics is possible, and thus an immense variety of musical tones can be imitated. The beauty of the quality of the diapason and flute tones is remarkable, and the full pedal notes come out excellently.

There can be no doubt that the loud-speaker electric organ in some form has come to stay. The small compass in which the equivalent of a large organ can be housed—the manual occupies no more room than a piano and the loud-speakers about that of a wireless set—the small cost, and the small running cost, together with the fact that it never requires tuning, are very real advantages which it possesses both for churches and for home use

We are indebted to Messrs. Boosey & Hawkes, Ltd., 295 Regent Street, London, W.1, for information on which the above article has been partly based.

Obituary Notices

Prof. A. Wiedemann

ALFRED WIEDEMANN, professor of Egyptology at the University of Bonn, died suddenly at the end of 1936 in Bonn, at the biblical age of over eighty years. Both on his father's and his mother's side he belonged to academic families: his father, like his elder brother, Eilhard, was a well-known professor of physics and chemistry, and so was his mother's father, Mitscherlich. Wiedemann himself, although devoted from his youth to Egyptology, felt always a keen interest in natural history and anthropology, and was one of the first among his Egyptological fellow-students to become enthusiastic over de Morgan's theories on Neolithic Egypt. To the latter's book on the tomb of Naqada he contributed an exhaustive study on the methods of burial in the Naqada necropolis, and the origin of the Egyptian people: it was characteristic of Wiedemann to attempt to draw historical conclusions by interpreting Egyptian religious texts and Egyptian rites in the light of recently established archæological facts.

Wiedemann devoted much labour to the study of Egyptian religion, and he will perhaps be best known to the British public through his contribution to the *Proceedings of the Society of Biblical Archæology*, of which he was a member, and through his "Egyptian Religion", an entirely revised translation of a German book by himself. Maspero, on reviewing the German edition, regretted the lack of an elaborate bibliography imposed on Wiedemann by the editor. He alludes evidently to the notes in Wiedemann's "Egyptian History" and in his Commentary to the second book of Herodotus, where an almost incredible mass of information is put together from public and private museums, from publications and accounts of all times and countries, in which the student could find quoted nearly every opinion on any subject treated, every bit of an inscription, every scarab detected anywhere by the author, registered. This tremendous work has rendered great service, but unfortunately Wiedemann declined to make any distinction between important and less important material, and the reader found himself to a certain extent drowned by the flood of monuments big and small, and sometimes difficult of access. Wiedemann was more a sceptic than a critical spirit, and he was neither a philologist nor a historian in the narrower sense of the words. Some of his translations are excellent: his remarks on the age of Memphis against Erman's theory that the city was not founded until the Sixth dynasty, and his opposition to the attribution of the tomb at Naqada to Menes, were sound, but in both cases he missed the real point: the Naqada tomb certainly dates from the beginning of the First Dynasty, and Memphis, although existing before as a settlement, took its name from the pyramid of King Phiops.

Wiedemann disliked the sometimes too systematic way in which Erman, his pupil Sethe, and Eduard Meyer treated the language and history of Egypt. He was unjust to the undoubted achievements of these scholars, and finally resigned from collaboration in Egyptological work, being aware of the gulf which divided his methods from those of nearly all Egyptological scholars in the twentieth century. He devoted himself entirely to the study of the history of Godesberg, the native village (and now town) of his wife, his best companion in life and work.

Wiedemann was the pupil of Lepsius, Ebers and Maspero, and he was strongly influenced by the last. But he lacked the facility with which Maspero connected any new facts with his own knowledge, and he was more of a collector of sometimes very important material than a systematic worker. Maspero rightly once said of his work, that it had allowed many others to do original work, meaning that without the many references in Wiedemann's books and the many texts published by him (sometimes in small autographic pamphlets, which have become very rare), other scholars would never have been able to produce their own dissertations. This is true, and no living Egyptologist ought to forget what he owes to Wiedemann, even if many of his books and pamphlets are out of date. What is perhaps more, Wiedemann was always ready to allow anybody to make use of his library, his small but interesting collection of antiquities, and of his valuable copies, which sometimes contained passages destroyed since Wiedemann had copied them, perhaps so early as 1882–83. I have seen W. Max Muller spending weeks in Bonn in order to take notes from Wiedemann's archives.

A man so sociable as Wiedmann would naturally be a good teacher, he would put everything he knew and had at the disposal of his pupils, he would also open his house to his students, not only giving many of his lectures at home but also inviting his students on his regular Tuesday evenings, and, together with his wife, looking after them whenever they needed help. All who knew Wiedemann in his best years, before the War took his son from him and the inflation annihilated his fortune, will think with pleasure and gratitude of him and his home.

F. W. FREIH. V. BISSING.

WE regret to announce the following deaths:

Mr. R. J. Mitchell, C.B.E., chief engineer and designer of the Supermarine Aviation Works, on June 11, aged forty-two years.

Mr. J. L. Stocks, vice-chancellor of the University of Liverpool, formerly professor of philosophy and public administration in the University of Manchester, on June 13, aged fifty-four years.

News and Views

The Ultra-Centrifuge in Biochemistry

THE substance of lectures by Prof. The Svedberg, delivered in Oxford earlier this year at the inauguration of an ultra-centrifuge in the Department of Biochemistry of the University, is printed as a supplement to this issue of NATURE. The work described represents the culmination of a definite stage in Prof. Svedberg's research with the ultra-centrifuge. By a remarkable feat of engineering, he has succeeded in applying a simple principle to the measurement of molecular weights in a region which seemed inaccessible except through osmotic methods; and since these gave no information as to molecular homogeneity, no idea could be reached of the individual molecular weights of a possible mixture. His ultra-centrifuge, capable of reaching with a rotor of 180 mm. diameter speeds of at least 66,000 revolutions per minute and forces of 300,000 times gravity, seems to be for the moment the only method of getting adequate resolution in the 'mass spectrum' of a mixture of proteins. It is driven by oil turbine and has a horizontal rotor running in hydrogen at a pressure of about 25 mm. Particularly interesting is his mention of the experiments upon the best forms of steel to be used in rotor construction. They indicate all too briefly how much experimental work has been needed to evolve a final form of the apparatus. The studies upon proteins have clearly arisen in Uppsala from the long-continued interest of Prof. Svedberg in colloids. Even before the development of the recent work, he had already made valuable contributions to colloid chemistry; but these must be regarded as of minor importance in the light of the discoveries here summarized.

THE significance for biochemistry of the new work can scarcely be exaggerated. For the first time, it has been possible to know whether a protein solution is homogeneous, and knowing this to define quickly the number of molecular species present in a mixture. The latter enables us to follow the entry and presence of a foreign protein in such a medium as the blood plasma; the implications of this for a study of diseased conditions are clear. It also provides a means of following changes in molecular weight produced by varying treatment of a pure protein such as albumen. In this way it has been shown at Uppsala that slight changes in hydrogen ion concentration (which have always been realized to be of great importance in biochemistry), can cause either reversible or irreversible dissociation of a protein. Further, it is remarkable that in several cases there should be similar changes induced by crystalloids, sometimes present only in traces. A particularly striking instance is recorded for the effect of 0·001 gm. per cent of thyroxin upon a solution of thyroglobulin. Such effects, and there seem to be many of them, can scarcely fail to throw light upon the intimacy of the cell itself, where the proteins in their colloidal relations form one of the most significant features of life. The final table which records the analysis of all the proteins so far studied is remarkable for the regularities that have come to light. With few exceptions, it seems that the molecular weights of the proteins fall into well-defined multiples of 17,600. Here for the first time, we feel that there is some chance of reaching the protein ultimately by the methods of organic chemistry, since these results signify some underlying simplicity of construction.

Agriculture and Industry

IN his recent Mather Lecture to the Textile Institute on "Agriculture as a Potential Source of Raw Materials of Industry", Sir Harold Hartley described the present-day uses of many agricultural products for industrial purposes, and indicated some possibilities of further expansion. His method of approach was that of the short-term extrapolator rather than that of the Utopian dreamer, who, although a more successful prophet as a rule, is apt to disregard the mundane but essential element of cost. Sir Harold left the sphere of social economics severely alone, but he emphasized that development of agricultural industries would promote closer co-operation and better understanding between farm and factory. Only about 12 per cent, by value, of the world's agricultural production is now used for industrial purposes, but the proportion is raised to one third if forest products be included. In spite of the triumphs of the chemist, first in revealing the structure of many organic molecules, and then in synthesizing many natural products, or in processing them, the factory cannot compete with Nature in the cheap production of complex organic compounds; for supplies of cellulose, the key substance of fibrous structures, we must always rely on the plant. The future lies not in competition between Nature and the chemist, but in their closer association to produce the materials needed by man. Such a development of the use of agricultural products will help to conserve our supplies of coal and oil, for whereas these represent wasting capital assets, plant products, ever renewable by solar radiation, represent revenue without debit to capital.

IN the United States the Farm Chemurgic Council is working "to advance the industrial use of American farm products through applied science", and its members meet annually at Dearborn to discuss their problems. Among the many difficulties confronting American agriculture are soil erosion, loss of fertility due to continuous cropping, displacement of the horse by the tractor, and decreasing exports and increasing imports of farm products. It is hoped to combat some of the bad effects of these conditions by growing new crops to replace imported products, by finding new outlets for established crops, and by better utilization of agricultural waste. Among the new crops are the soya bean, which now covers six million acres. Substances extracted or made from it have manifold uses, and Henry Ford has built a large plant for making plastics out of the meal. Tung oil, valuable for paint and varnish making, is to be derived from extensive plantings of the tung-oil tree; and, also in the Southern States, the quick-growing Southern Pine has been planted over 200 million acres to provide pulp for newsprint and as a raw material for rayon and 'Cellophane'. Among the new outlets for old crops are the use of cotton fabric for reinforcing tarred roads, of inferior cotton and cotton linters for making cellulose derivatives, and of maize for the production of starch, dextrin, corn syrup, dextrose, corn oil and cake. Also under investigation is the utilization of the enormous quantities of straw, cotton stalks, and husks that now run to waste. By promoting agricultural industries on the above lines, it is hoped to put the farmer financially on his feet, and to make him a better customer of the factory.

Total Solar Eclipse of June 8–9.

THE fact that the expedition of the National Geographic Society and the U.S. Naval Observatory was accompanied by engineers and announcers of the National Broadcasting Company of America has led to the overlooking of the other expeditions organized to observe the recent total solar eclipse (see NATURE of June 12, p. 993). It is good to report that Mr. C. B. Michie, who led an expedition from New Zealand with the aid of the Royal New Zealand Navy also to Canton Island, shared in the good luck in the form of fine weather that came the way of the American party, and secured good photographs of the corona with several very long streamers. Further, it transpires that the Princeton party to Chembote in Peru—and it is hoped the Japanese party there also—had fine weather for the actual eclipse, though as at Canton Island weather prospects were anything but favourable not long before the eclipse. The value of the results obtained by the various parties (and by the party from Princeton, the Franklin Institute and the Cook Observatory on the S.S. *Steelmaker* near the point of maximum totality) cannot yet be assessed, but in view of the number of experienced observers concerned, one may confidently look forward to results of very considerable importance.

International Peace

THE annual report of the Director of the Division of Intercourse and Education of the Carnegie Endowment for International Peace for 1936 pleads for further support for genuine world organization and collective security through an effective world police force. Dr. Murray Butler refers to the existence of a deep-seated popular sentiment against war and to the necessity of this opinion finding expression not merely in emotional outbursts but also in support of definite policies of social, economic and political co-operation and the substitution of judicial process for the threat of force in settling international differences. The advocates of economic nationalism and of neutrality, he said, are making a most insidious attack upon the foundations of prosperity and of peace, for the first involves ultimate national suicide and world-wide disaster and the latter neglect of the highest international obligations. Dr. Butler pointed out that the wars which are most threatening at the present time are between fundamental philosophies of life and of public order, and he referred to the dangers confronting democratic nations.

THE Inter-American Conference at Buenos Ayres in December was the brightest feature of the year and received support from public opinion in both American continents. The report refers to co-operation with the International Chamber of Commerce and the adoption in August by the Joint Committee of thirteen practical recommendations for improving commercial relations between nations and dealing with monetary stabilization. Reference is also made to the distribution of literature, to the Leadership Training Conference held in Des Moines, Iowa, to the work of the visiting Carnegie professors, to the International Relations Clubs, of which 805 have now been formed, as well as to the work of such associated institutions as the American Academy of Political and Social Science, the Institute of Public Affairs at various universities, the Institute of Foreign Affairs, Earlham College, Richmond, Indiana, and the Institute of Pacific Relations. Details of similar work of the Division in Europe are included, indicating the great extent to which the Division utilizes the opportunities afforded by existing organizations for carrying out its educational work.

Archæological Discoveries in Northern Syria

SIR LEONARD WOOLLEY'S first report on the current season's work of the British Museum's Archæological Expedition to Northern Syria records important discoveries, which throw fresh light on the Hittite occupation of that area and would seem to confirm references in the Biblical narrative to the relations of the Hittite people and the inhabitants of Palestine in the patriarchal age, which hitherto have been regarded as anachronisms. The expedition, Sir Leonard reports (*The Times*, June 12), has completed its first season's work in the Amk plain, inland from Antioch. The time available was brief, as excavations begun last year at Mina had to be completed; but an isolated area about twenty yards square in what was believed to be the aristocratic quarter of the city, opened up to a depth of 13 ft., has revealed a magnificent building, one of the finest as yet found in northern Syria. This structure is Hittite. It was built of basalt, mud-brick and timber. The approach was from a tile-paved area by way of a flight of basalt steps between platform buttresses, and led through a colonnade into a wide entrance court. The building had been destroyed by a fire; but the chambers adjoining the court were rich in finds of pottery, local and imported, including

Cypriote pottery of the Bronze age. An important find consisted of portions of two literary texts, which, as the oldest cuneiform documents as yet found in northern Syria, may be expected to yield results of considerable historical interest. The date of the building can be fixed with tolerable accuracy, as information from the main excavation of the year, which was on a much larger scale, indicates consecutive periods ranging from the twelfth back to the sixteenth or seventeenth century B.C. Here, below cremation graves, was found a house, which on the evidence of Mycenæan pottery belongs to the thirteenth or fourteenth century B.C. Inscribed tablets afford evidence of the existence of a royal library. In the fourth level, dated at the sixteenth century B.C., was found a house which in its details corresponds to the larger building previously described, and being characteristically Hittite, serves also to place the Hittite occupation of northern Syria at a much earlier date than hitherto accepted.

Swanscombe Skull: Committee of Investigation

THE character of the Swanscombe skull and the conditions of its discovery both in themselves and in relation to the Piltdown skull, suggested that a certain suspension of judgment was advisable for further consideration of the evidence, before accepting the find at its face value as inferred by Mr. A. T. Marston on his announcement of the find (see NATURE of October 19, 1935, p. 637 and August 1, 1936, p. 200). A report was also promised on the palæontological evidence, which clearly would have an important bearing on any conclusion to be drawn. So far, anthropologists, while admitting the importance of the discovery as reported by Mr. Marston, have been inclined to caution. An announcement, therefore, is welcome that the Royal Anthropological Institute has appointed a committee to investigate the evidence which Mr. Marston has collected, and to co-operate with him in the further investigation of the site. This committee consists of Mr. M. A. C. Hinton, keeper of zoology, British Museum (Natural History), (*chairman*), Mr. K. P. Oakley, Department of Geology, British Museum (*secretary*), Prof. P. G. H. Boswell, Imperial College of Science, London, Prof. W. E. Le Gros Clark, Department of Anatomy, University of Oxford, Mr. H. G. Dines, Geological Survey of Great Britain, Mr. C. F. C. Hawkes, Department of British Antiquities, British Museum, Prof. W. B. R. King, Department of Geology, University College, London, Mr. A. T. Marston, Dr. G. M. Morant, Galton Laboratory, University College, London, and Mr. S. Hazzledine Warren.

The Empire Cotton Growing Corporation

AT a meeting of the Administrative Council of the Empire Cotton Growing Corporation held in Manchester on May 25, it was announced that the Corporation has recently acceded to a request from the Indian Central Cotton Committee that Dr. T. G. Mason should be permitted to spend some months in India to advise in connexion with an investigation into the causes of the periodic failure of the cotton crop in the Punjab. It was also reported that in letters that had been received from Prof. J. W. Munro, who is making a tour in Africa to advise the Corporation on its work on cotton insect pest control, he has written enthusiastically of the high quality of the work that was being carried out by the Corporation's staff, and recommended that it should continue to receive full support. An addition to the staff in Nyasaland may be necessary. It was naturally impossible to say whether it would prove possible to devise any practical measures for controlling these pests, but pests constituted the limiting factor in cotton-growing throughout considerable areas in Africa, and the Corporation should therefore leave nothing undone which might bring to light any information that might possibly lead to a reduction in the loss of crop thus caused.

Genetic Theory and Practice in the U.S.S.R.

IN a note on genetics in the U.S.S.R. (NATURE, 139, 185; Jan. 30, 1937), reference was made to the empirical work of Michurin on the hybridization of fruits, and his published work was said not to have been translated into any foreign language. Our attention had been directed to the fact that a translation, in an abridged form, is available for reference in the Bureau of Plant Genetics at Cambridge. The short published abstracts of the Bureau (*Plant Breeding Abstracts*, 5, 56, 376 and 7, 122) make the character of Michurin's work fairly clear. Like the recent work of Burbank in the United States, it belongs to the period of Kolreuter. It uses the assumptions and deals with the problems that were in favour in the late eighteenth century. Indifference to the refinements of later work has led Michurin, as it did Burbank, to somewhat fantastic conclusions in physiology and genetics. The reason for Michurin's indifference, however, is peculiar and significant. He states that the Mendelian principles are not in accordance with the dialectic of Engels, and must therefore be disregarded. It seems that Aristotelianism is appearing in a new quarter under a new guise.

Mechanized Farming

THE report on the discussions at the Oxford Conference on Mechanized Farming held in January last has been published. It contains the opening and concluding addresses given by Mr. C. S. Orwin and Mr. Roland Dudley respectively, and full accounts of the discussion that followed the papers dealing with tractor performance and row-crop cultivation, cultivations, the maintenance of fertility, grass drying and combine harvesting. Both the practical and scientific points of view are well represented and the publication is clearly a valuable complement to the papers themselves. The complete Proceedings of the Conference (2 vols.), which includes both the papers and discussions, may be obtained from the Conference Secretary, 10 Parks Road, Oxford, price 2*s*. 6*d*. post paid.

International Congress for the History of Science

THE arrangements for the Fourth International Congress for the History of Science, to be held in Prague on September 22–27, are proceeding. The President of Czechoslovakia, Dr. Eduard Beneš, has agreed to give his patronage, and with him are Dr. Em. Franke, Minister of Education, Dr. Kamil Krofta, Minister of Foreign Affairs, Dr. Josef Zadina, Minister of Agriculture, the rectors of the Czechoslovak universities and corresponding schools, the presidents of the academies of science and of the scientific societies of Czechoslovakia, and the Chief Mayor of Prague. On the Committee of Honour, prominent leaders in industry and science in Czechoslovakia are represented. For the plenary meetings lectures have been promised by Prof. B. Němec, formerly rector of the Charles University, president of the National Research Council of Czechoslovakia; Prof. O. Grosser, formerly rector of the German University in Prague; Prof. K. Studnička, of the Charles University; Prof. Gino Loria, of the University of Genoa, formerly president of the International Academy for the History of Sciences; Prof. Abel Rey, of the Sorbonne, director of the Institute for the History of Sciences and Technics. About a hundred papers, from Czechoslovakia and from Belgium, England, France, Germany, Italy, Poland, Portugal, Rumania, U.S.S.R., and Yugoslavia, have already been received. Members of the Congress will enjoy reductions on the railways of Czechoslovakia and of the other countries interested. Further information can be obtained from the general secretary of the Congress, Prof. Fr. Ulrich, Albertov 6, Praha II.

Institute for Research in Metals, Sendai

PROF. KÔTARÔ HONDA has lately completed his twenty-fifth year as professor of physics in the Tôhoku Imperial University, and the occasion has been commemorated by the publication of a special volume of the Science Reports of that University, contributed by his pupils and by friends from many countries. This substantial volume, of 1,126 pages, is an indication of the prominent part that Prof. Honda has played as teacher and also as director of the very active Institute for Research in Metals at Sendai. As might be expected from the special interests of Prof. Honda, from his work at Gottingen onwards, many of the papers, some sixteen in all, deal with the magnetic properties of metals, but the work of the Institute has covered a wide field in metallurgy, and most branches of the physical study of metals are represented. Another group treats of transformations of alloys in the solid state, including steels. The development of improved steels for permanent magnets has been one of the most important results of the investigations at Sendai, the discoveries made there having had profound industrial effects, through reducing the size of magnets and even of enabling them to take the place of electromagnets in machine tools, etc. Terrestrial magnetism is also represented, whilst other papers describe investigations in chemistry. Many well-known names are to be found among the contributors, and the occasion has been used to present surveys of the position of knowledge concerning several of the properties of alloys of current interest.

Transmission of Electricity in France

AN instructive lecture was given by P. M. J. Ailleret to the Transmission Section of the Institution of Electrical Engineers on April 29, the subject of the discourse being recent developments of electric transmission in France. The French system includes lines operating at 110, 120, 150 and 220 kV. The reason for this difference is partly historical and partly geographical. The grid was begun in France in 1920, the pressure used being 120 kV.; a few years later it was considered necessary to raise it to 150 kV., and the first 220 kV. line was erected five years ago. Every time a new line was proposed which did not interest existing producers, a new company had to be formed, and the whole system was financed by the co-operation between producers, distributors and interested industries. No less than thirty-nine companies were formed to finance the construction of the lines, but the responsibility for operation is entrusted to a fairly small number of them. Another reason for the use of several voltages is that in France the price of coal varies much more from one part of the country to another than it does in England. Hydro-electric generation is concentrated in limited mountain areas and nearly half the total production comes from this source. Some regions which are rich in water power have practically no local consumers, others have an important electrochemical and electrometallurgical load, constant during the day, but with seasonal fluctuations which are advantageously combined with the usual loads of a distribution system. For these reasons a voltage of 220 kV. has in some cases been necessary. An eleven mile underground cable at this voltage was found necessary to transmit the energy from the south-east to the St. Denis power station through a densely populated suburban area. This oil-filled cable can carry 150,000 kilovolt-amperes.

Fishing Gear

THE third edition of "An Account of the Fishing Gear of England and Wales" (H.M. Stationery Office. 6*s*. net), has recently been issued, since the first publication in 1923, a fact which bears full witness to its value. The subject is a vast one, for Mr. Davis's account ranges from the single hook handline to the modern otter trawl, from the whelk-pot to the fish weir nearly a quarter of a mile long. The most important modern fishing gears—otter trawl and drift net—are dealt with in detail, and the methods of shooting, fishing and hauling clearly explained. In this connexion it may be mentioned that many east coast drifters now shoot mackerel-nets forward, rather than over the stern. There is a section on the Danish plaice seine, and Mr. C. F. Hickling has rewritten the account of the Vigneron-Dahl trawl. Many of the instruments of the inshore fisherman described are now disused, or obsolescent, so that parts of the account are chiefly of historic interest. It is interesting to see how similar types of net have been evolved by fishermen on different parts of the coast, and how one type of net grades into another. The author points out that the Saltash tuck-seine is practically a trawl, and the Beer 'fly-backed otter trawl' a seine The braiding and setting of nets and their preservation is dealt with. Indeed, the use of Mr. Davis's paper would make clear any reference to the methods of fishing around the British coasts, or the description of the shape and construction of any net.

St. Kilda Papers 1931

A publication entitled "St. Kilda Papers 1931" has just been issued, and contains, in addition to a foreword, bibliography and large-scale map, reprints of eleven papers previously published in various scientific journals. These papers, which deal with the mice, the breeding birds, the early autumn migration in 1931, the St. Kilda wren, the Coleoptera, the flora and the vegetation of St. Kilda, comprise the chief scientific results of an expedition to the island in the summer of 1931, the year following the evacuation of the islanders. As "St. Kilda Papers 1931" is limited to an edition of only fifty copies, none is available for sale; but as the publication is intended as a basis for any future scientific work on the island, twenty-five copies have been presented to leading public libraries and to the libraries of learned scientific societies for reference purposes. Any further information relative to this publication or to the deposition of the library copies can be obtained from Mr. Malcolm Stewart, Hawridge Court, Nr. Chesham, Bucks.

The World Power Conference

We have received a summary of the annual report for 1936 of the World Power Conference, prepared by the Central Office, 36 Kingsway, London, W.C.2. The chairman is Sir Harold Hartley (Britain) and the vice-chairmen are O. C. Merrill (United States), G. T. T. Bakker (Netherlands) and M. Kamo (Japan). The plenary conference was held in Washington on September 7–12, 1936, and was attended by about 3,000 members from fifty-four countries. Year book No. 1 was published in October 1936, and it is hoped that No. 2 will be published in September next. Statistics on manufactured gas and coke will be added in this and subsequent year books. The work of the international sub-commission on special cements is going steadily forward, and work on an international technical dictionary in connexion with dams will soon be begun. The International Executive Council has unanimously accepted the invitation of the German National Committee for the second chemical engineering congress to be held in Berlin in 1940. There is little doubt that the fourth World Power Conference will take place in 1942, thus preserving the interval of six years between successive plenary meetings.

University of Lausanne

The fourth centenary of the University of Lausanne was celebrated on June 4–5, when honorary degrees were conferred on the following, among others: Sir Maurice Amos, Quain professor of comparative law in University College, London (Doctor of Laws); Sir Frederick Gowland Hopkins, Sir William Dunn professor of biochemistry, in the University of Cambridge (Doctor of Medicine, *in absentia*); Prof. G. Barger, professor of chemistry in relation to medicine in the University of Edinburgh (Doctor of Pharmacy); and Prof. G. Rudler, Foch professor of French in the University of Oxford (Doctor of Letters). The University of Lausanne began in 1537 as the first college for the training of Protestant ministers, and other faculties were added during the nineteenth century.

National Baby Week

The National Baby Week Council announces that National Baby Week will be held on July 1–7. The theme selected for discussion and publicity this year is "Housing and Home in Relation to Maternity and Child Welfare", and a housing manifesto has been issued embodying certain ideals and ideas that may serve as a basis for discussion. This and other particulars may be obtained on application to the Secretary at 117 Piccadilly, London, W.1.

Announcements

The University of Athens, on the occasion of its centenary celebrations, has conferred on Prof. F. G. Donnan, University professor of chemistry in University College, London, the honorary degree of D.Sc.

Mr. Edgar P. Chance, of Bulwell, Burchetts Green, near Maidenhead, has arranged a second exhibition of his collection of British birds' eggs to be held at the above address on June 25–26. The exhibition comprises about 150 drawers or trays selected from Mr. Chance's collection. Admission, from 10 a.m. until 8 p.m., is free.

A Conference on Magnetism will be held in the Physics Department of the University of Manchester on July 1–2, under the auspices of the Manchester and District Branch of the Institute of Physics. Prof. W. L. Bragg, the chairman of the Branch, will preside over the Conference and the following will give lectures: G. Richer, D. A. Oliver, Prof. N. F. Mott, Dr. C. Dannatt, Dr. E. C. Stoner, and Dr. A. J. Bradley. Visitors will be welcome, and further particulars may be obtained from Dr. C. Sykes, Research Department, Metropolitan-Vickers Electrical Co., Ltd., Trafford Park, Manchester, 17.

The fifty-sixth annual meeting of the Society of Chemical Industry will be held at Harrogate on July 5–9 under the presidency of the Right Hon. Lord Leverhulme. Prof. G. G. Henderson, recipient of the Society's Medal, will give an address entitled, "A Retrospect; Notes on some Development in the

The Ultra-Centrifuge and the Study of High-Molecular Compounds

By Prof. The Svedberg, University, Uppsala

Introduction and Theory

An atomic weight determination of a 'natural' mixed element by chemical methods gives only a mean value. It does not furnish any information about the individual weights of the different atomic species or isotopes constituting the mixture. Such data may be collected by mass-spectroscopic studies.

Molecular weight determinations by osmotic pressure and viscosity methods likewise give only mean values. Now in the case of high-molecular compounds, there are often present in the same solution a number of different molecular species differing in mass and shape. The properties of the solution as well as of the dried substance depend to a great extent upon the distribution of the different molecular species. A molecular weight analysis is therefore of considerable importance when studying high-molecular compounds. The ultra-centrifuge enables us to carry out such an analysis.

The interest in high-molecular compounds has been rapidly growing during recent years. The role of proteins in the organism is a matter of life and death, and the elucidation of the constitution and physico-chemical properties of these substances is therefore an urgent task. Certain industries dealing with proteins are also interested in progress in this field. For our understanding of the properties of polysaccharides, such as starch, glycogen, cellulose and their derivatives, as well as the behaviour of the associated hydrocarbons and the high-molecular dyestuffs, it is necessary to study their molecular size under various conditions. The ultra-centrifuge offers a possibility of solving many of the problems in question.

What we aim at in ultracentrifuging is an accurate determination of the molecular sedimentation in a strong centrifugal field. Two lines of approach are possible. We can measure the rate of settling of the molecules—the sedimentation velocity—or we can measure the competition between settling and diffusion—the sedimentation equilibrium—which is finally reached after prolonged centrifuging. In the former case we need an independent determination of the diffusion constant in order to calculate the molecular weight. The latter method furnishes directly the molecular weight[1-7].

The sedimentation velocity reduced to unit centrifugal field and to standard frictional conditions represented by water at 20° C. is called the sedimentation constant.

$$s = \frac{dx}{dt} \cdot \frac{1}{\omega^2 x} \cdot \frac{\eta}{\eta_0} \cdot \frac{1 - V\rho_0}{1 - V\rho} \quad . \; . \; . \quad (1)$$

where dx/dt is the observed translational velocity, x the distance from centre of rotation, ω the angular velocity of the centrifuge, η and ρ the viscosity and density of the solution, η_0 and ρ_0 the same quantities for water at 20° C., and V the partial specific volume of the solute.

From the sedimentation constant s and the diffusion constant D, we get the molecular weight

$$M = \frac{RT\,s}{D(1 - V\rho)} \quad . \; . \; . \; . \; . \quad (2)$$

where R is the gas constant and T the absolute temperature.

The knowledge of the distribution of concentration c with distance from centre of rotation in equilibrium enables us to calculate the molecular weight from the following formula:

$$M = \frac{2\,RT \ln c_2/c_1}{(1 - V\rho)\omega^2(x_2^2 - x_1^2)} \quad . \; . \; . \; (3)$$

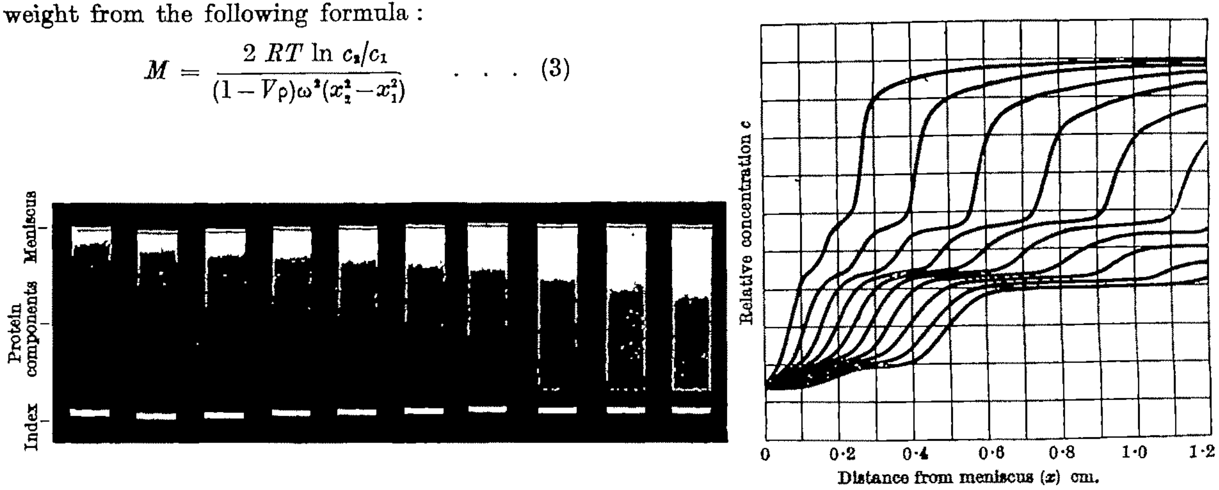

Fig. 1.

(*Left*) SEDIMENTATION PICTURES OBTAINED BY MEANS OF THE LIGHT ABSORPTION METHOD; AND (*right*) CURVES OF CONCENTRATION DISTRIBUTION FOR *Limulus* HÆMOCYANIN AT pH 6·8; SEDIMENTATION CONSTANTS OF COMPONENTS, $56{\cdot}6 \times 10^{-13}$, $34{\cdot}6 \times 10^{-13}$, $16{\cdot}1 \times 10^{-13}$, $5{\cdot}9 \times 10^{-13}$; CENTRIFUGAL FORCE 120,000 TIMES GRAVITY; TIME BETWEEN EXPOSURES 5 MIN. (I.-B. ERIKSSON-QUENSEL[20]).

If the substance is electrolytically dissociated, the disturbing influence of the charges may be eliminated by the addition of a non-sedimenting electrolyte.

APPARATUS AND EXPERIMENTAL PROCEDURE

In order to determine molecular sedimentation velocities, centrifugal fields of high intensity have to be used so as to shorten the time of observation, thus avoiding undue blurring of the boundary due to diffusion. In sedimentation equilibrium measurements, the centrifuging is carried on long enough at a comparatively low speed so as to attain an equilibrium between sedimentation and diffusion.

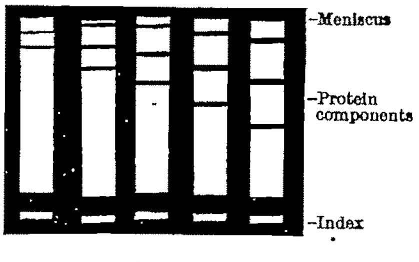

Fig. 2.

SEDIMENTATION PICTURES FOR *Limulus* HÆMOCYANIN OBTAINED BY MEANS OF THE TŒPLER *Schlieren*-METHOD AT pH 6·8, SHOWING THE FASTEST THREE SEDIMENTING COMPONENTS OF $s = 56{\cdot}5 \times 10^{-13}$, $34{\cdot}6 \times 10^{-13}$, AND $16{\cdot}1 \times 10^{-13}$; CENTRIFUGAL FORCE 120,000 TIMES GRAVITY; TIME BETWEEN EXPOSURES 5 MIN. (I.-B. ERIKSSON-QUENSEL[16]).

In both cases a small quantity of the solution to be studied is enclosed in a sector-shaped cell provided with plane-parallel ultra-violet transparent windows and rotated at constant (or but slightly changing) temperature. Freedom from convection currents is an essential feature of the procedure. Given the height and thickness of the column of solution and its distance from the centre of rotation, all other characteristics of the ultracentrifuge can be unambiguously derived. The dimensions of the sample of liquid determine the size of the observation windows of the cell and its outer diameter. The dimensions and situation of the cell holes determine the size of the rotor and its shape, as well as the maximum speed attainable with given rotor and cell materials.

In velocity measurements, the column of solution should be high enough to give sufficient space for undisturbed sedimentation. If it is too short, the molecules reflected from the bottom of the cell (backward diffusion) will interfere with the sedimentation before sufficient data have been collected.

The diameter of the rotor should be large enough to allow of the cell being placed at a suitable distance from the centre of rotation. In velocity measurements, the accuracy is decreased if the sample of solution studied is rotating with too small a radius. The part of the liquid where the concentration is independent of distance becomes impoverished too quickly, decreasing with time inversely as the square of the distance from the centre of rotation.

For low-speed runs, the rotor may be made with cylindrical outline, which has the advantage of good heat-exchange with the surrounding casing. At high speed, an oval shape with two cell holes—one for the solution cell and one for the balancing cell—must be chosen in order to reduce the strain. A vane of proper diameter screens off false light.

As rotor material chromium-nickel steel has proved the best. The highest centrifugal forces (1,000,000 times gravity) were reached using hard steel, but at the same time accidents during the test runs were often met with. Soft steel has been found more reliable, especially in the case of big rotors.

To diminish friction, the rotation has to take place in a medium of low viscosity. Vacuum is advisable only when the construction is such that practically no heat from the bearings is transferred to the rotor. An atmosphere causing some friction but possessing a high heat-conductivity is preferable. In those circumstances, the heat generated will be conducted away so quickly that satisfactory thermal conditions can be permanently maintained and convection currents avoided. For low-speed runs, hydrogen at normal atmospheric pressure may be used. For higher speeds, the hydrogen pressure should be cut down to about 25 mm. in order to reduce the friction without diminishing the heat-conductivity of the gas.

Up to speeds of about 20,000 r.p.m. or even somewhat higher, the rotor can be supported by ball-bearings. At high speed (20,000–160,000 r.p.m.) they become unreliable and have to be replaced by journal bearings. In the Uppsala machines oil-lubricated white-metal was chosen. With good balancing, the bearing pressures are very low, hence the surface of the bearings may be kept small and the heat-production and energy loss by friction low. For a recent type of our rotors it is 0·7 kW. at 60,000 r.p.m.

If the rotor is not self-balancing, it is of considerable importance not only that it should be in perfect balance, both statically and dynamically, but also that provision should be made for some sort of damping device to take care of small accidental irregularities in the movement and to prevent such disturbances from building up dangerous vibrations. A special type of damping bearings was therefore developed at Uppsala. The bearing surface is divided into six parts, three of which are fixed and three others form the ends of moving pistons acted upon by oil pressure. The movement of one of the pistons can be adjustably limited by means of a micrometer screw.

In the air-driven self-balancing ultra-centrifuge developed by Beams[8], Bauer[9], and Wyckoff[10], a light duraluminium rotor is hanging on a thin steel shaft and supported by an air-film bearing. The friction, and consequently the energy consumption, are therefore very low. The air-turbine is sealed off from the vacuum chamber in which the rotor moves by surrounding the vertical shaft with an oiled gland-shaped bearing.

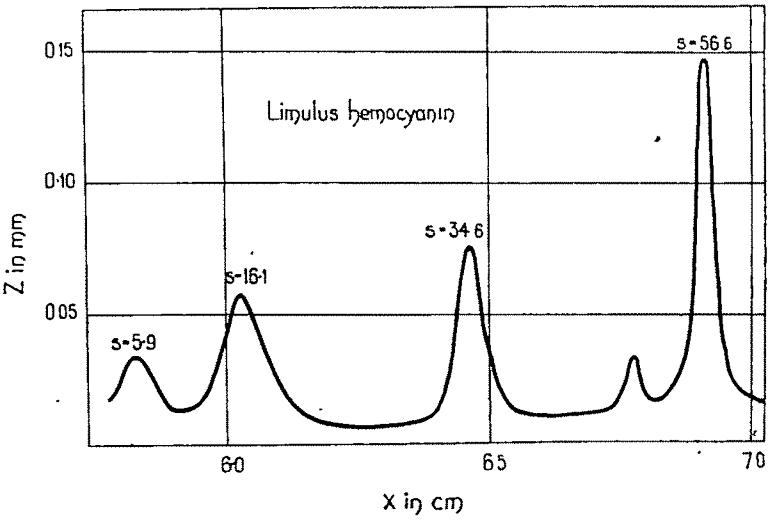

Fig. 3.

SEDIMENTATION DIAGRAM FOR *Limulus* HÆMOCYANIN OBTAINED BY MEANS OF THE REFRACTIVE INDEX METHOD AT pH 6·8 SHOWING THE SAME FOUR MAIN COMPONENTS AS IN FIG. 1 AND ALSO A SMALL AMOUNT OF A FIFTH ONE; CENTRIFUGAL FORCE 120,000 TIMES GRAVITY; TIME AFTER REACHING FULL SPEED 35 MIN. (K. O. PEDERSEN).

Direct electric drive with a heavy rotor self-balancing on top of a vertical shaft has proved very good for speeds up to 20,000 r.p.m.[11]. Beams has succeeded in spinning electrically a hanging duraluminium rotor supported by an air-film bearing up to 60,000 r.p.m.[12]. For driving a heavy rotor at high speed, turbines appear to be the best means[13,14,15]. Oil-turbines have been chosen by us for the following reasons. There is no danger of contaminating the atmosphere around the rotor by gas from the turbine. The same compressor may be used for delivering the lubricating oil and the oil operating the damping bearings. The output of our oil-turbines compares favourably with that of air-turbines of similar power dimensions. In recent constructions the energy consumption of the oil compressor motor at a centrifuge rotor speed of 60,000 is 2·8 kW.

For the calculation of sedimentation constants and molecular weights, knowledge of the temperature in the rotating sample is necessary. In low-speed runs the temperature of the cell may with sufficient accuracy be taken as equal to the temperature in the thermostat bath surrounding the rotor chamber. In high-speed runs with the oil-turbine centrifuge, a radiation thermocouple placed very close (0 15 mm.) to the surface of the rotor near the cell hole registers the actual temperature of the cell.

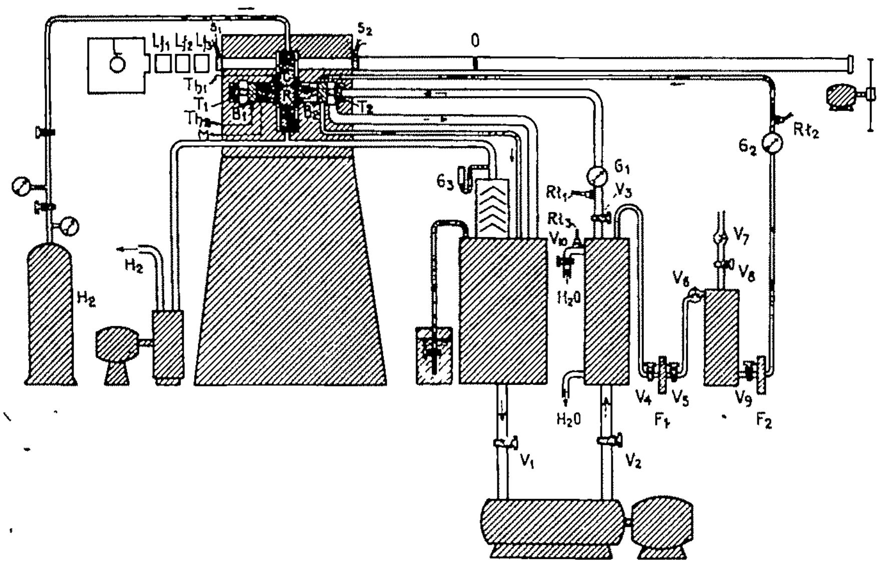

Fig. 4.

DIAGRAM OF THE HIGH-SPEED OIL-TURBINE ULTRA-CENTRIFUGE EQUIPMENT.

The angular velocity enters to the second power in the formulæ for sedimentation constant and molecular weight. The accurate determination of this quantity is therefore of great importance in ultra-centrifugal technique. In the case of direct drive by an A.C. motor, a measurement of the frequency of the electric current suffices, because with ball-bearings and the rotor running in hydrogen there is no noticeable slip. For the high-speed oil-turbine centrifuge, a stroboscopic tachometer was at first used. A more convenient magneto-electric method for speed measurement has recently been worked out. Part of the shaft of the centrifuge rotor is magnetized and surrounded by a two-pole soft iron armature provided with coils. This device constitutes a magneto-electric generator which produces an A.C. current of the same frequency as the revolutions per minute of the rotor. After amplifying, this current is fed to a vibration frequency meter or to an oscillograph.

The process of sedimentation is followed by optical means. Two different properties of the solute may be utilized for the determination of the concentration distribution in the rotating solution, namely, the light absorption and the refraction. In both cases the thickness of the layer of liquid studied necessitates long-focus lenses in order to avoid parallactic errors. When using the absorption method, photographic exposures of the sedimenting column are made from time to time by light of a wave-length absorbed by the solute. These pictures are then measured by means of a microphotometer and give the relation between concentration c and distance x from centre of rotation. Each molecular species is brought out as a step on the c–x curve (Fig. 1). The change in refractive index can be made use of in various ways. The simplest way is to apply the Tœpler *Schlieren*-method (A. Tiselius and K. O. Pedersen[16]). The different molecular species present are then recorded on the plate like the lines of a mass-spectrum (Fig. 2). A more accurate procedure to obtain the real concentration distribution in the sample studied is to take pictures of a finely ruled scale through the sedimenting column of solution by light of a wave-length which is not absorbed (O. Lamm[17]). By measuring the displacement of the lines, we get the concentration gradient dc/dx as a function of the distance from the centre of rotation. Each molecular species is therefore shown as a maximum on a curve (Fig. 3).

The resolving power of the ultra-centrifuge is given by the expression $\omega^2 xh$ where ω is the angular velocity, x the distance from centre of rotation and h the height of column of solution in the cell. Insufficient centrifugal force, $\omega^2 x$, may be compensated, therefore, by high column of solution, and vice versa. The method of rotor construction limits the maximum value for $\omega^2 xh$

attainable to $5 \cdot 8 \times 10^5$, which corresponds to a speed around 65,000–75,000 r.p.m., a rotor diameter of about 180 mm. and a height of column of solution of about 18 mm.

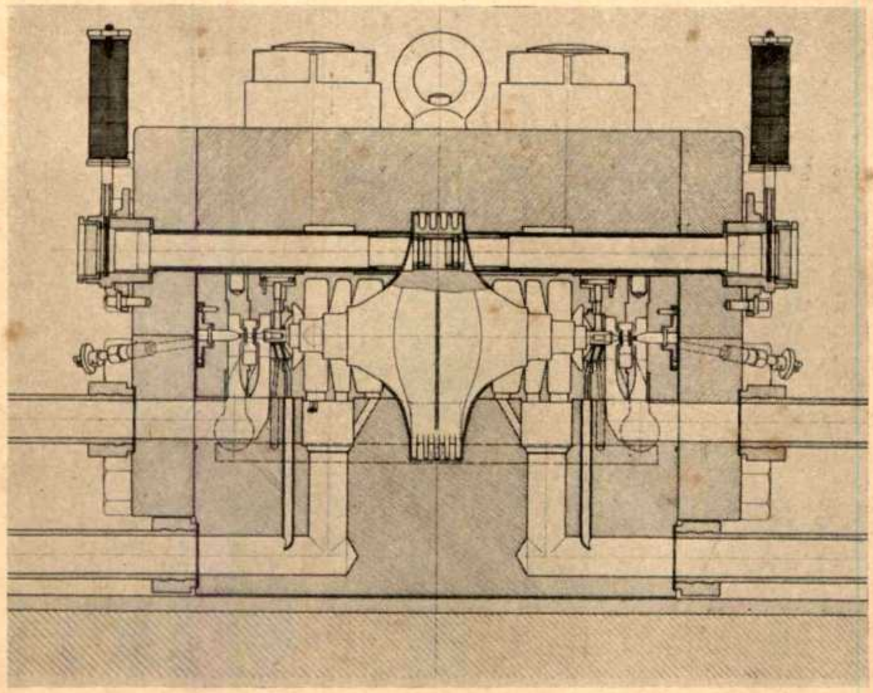

Fig. 5.
AXIAL SECTION OF THE OIL-TURBINE ULTRA-CENTRIFUGE.

The high-speed oil-turbine ultra-centrifuge equipment devised for sedimentation velocity measurements on substances of high molecular weight (in the case of proteins from 15,000,000 down to about 1,000) and for sedimentation equilibrium measurements on low-molecular substances is represented diagrammatically in Fig. 4. A detailed section of the centrifuge through the axis of rotation is shown in Fig. 5, and a photograph of rotor and cell in Fig. 6.

The rotor R (Fig. 4) is supported by horizontal bearings B_1 and B_2, and kept in rotation by the two small oil twin-turbines T_1 and T_2, one on each end of the shaft. Hydrogen is let in at the periphery and constantly pumped off so as to maintain a pressure of about 25 mm. Thermocouples Th_1 and Th_2 serve for temperature determinations of the bearings and the rotor. A beam of light from a mercury lamp L filtered through Lf_1, Lf_2, Lf_3 passes the cell C in the rotor on its way to the camera. The exposures are timed by means of the electromagnetic shutters S_1 and S_2. The stroboscope or the magnetic generator M enables the observer to measure the speed of the rotor. The pressure oil which feeds the turbines is produced by a special oil-compressor and cooled to a suitable temperature before entering the turbine chambers. The lubricating oil for the bearings passes through an oil filter and is controlled by the valve V_5. By changing the speed of the motor which drives the compressor and by operating the valve V_3, the pressure of the oil entering the turbines may be regulated so as to make possible measurements at any desired speed between 20,000 and 140,000 r.p.m. (corresponding to centrifugal forces 30,000–700,000 times gravity). The resistance thermometers Rt_1, Rt_2, Rt_3 and the manometers G_1, G_2, G_3 enable the operator to control temperature and pressure in the different parts of the machinery.

Fig. 7 shows the oil-turbine ultra-centrifuge with the upper part of the heavy steel casing lifted, laying bare the rotor and the turbine chambers. The cell with its sector diaphragm is in the vertical position, upside down. Behind the centrifuge is the lamp house and the filters. The two halves of the thick steel casing are held together by bolts of chromium-nickel steel firmly anchored in a

concrete foundation. Fig. 9 is a photograph of the whole installation showing, from right to left, the lamphouse, the centrifuge on its foundation, the camera and the oil-coolers and containers ; in the foreground are the steps down to the machine pit where the oil-compressor, the oil filters and the vacuum pump are mounted.

INVESTIGATIONS ON PROTEINS

Among the various groups of high-molecular compounds the mass analysis of which has been attempted by means of the ultra-centrifuge, the proteins stand out as an especially interesting and peculiar class[7,18,19].

A very striking but rather unexpected property of protein solutions discovered by the ultra-centrifugal analysis is the perfect molecular homogeneity. This means that the solution of a certain protein is either uniform with regard to molecular weight or contains a limited number of different molecular species, as a rule in equilibrium with each other. Change in protein concentration, in *p*H, or in concentration of other solutes present may bring about dissociation or association.

If the sedimentation proceeds so quickly that no appreciable diffusion takes place during a run, the molecular homogeneity can be tested simply by studying the degree of sharpness of the receding boundary (Fig. 8).

An example of the behaviour of a high-molecular substance become non-homogeneous by slight denaturation is given in Figs. 10 and 11.

In cases where the sedimentation proceeds more slowly, so that noticeable diffusion occurs during a run, the homogeneity can be tested by comparing the theoretical sedimentation-diffusion curves with the observed ones (Fig. 12).

A homogeneity test may also be performed by means of sedimentation equilibrium measurements (Fig. 13). Here the molecular weight values should be independent of distance from centre of rotation.

The dependence of a protein on *p*H is exemplified by the stability diagram of *Helix* hæmocyanin (Fig. 14). At the isoelectric point the protein contains only one component, but on lowering or raising the *p*H, points are reached where a very small change in *p*H causes a great change in the

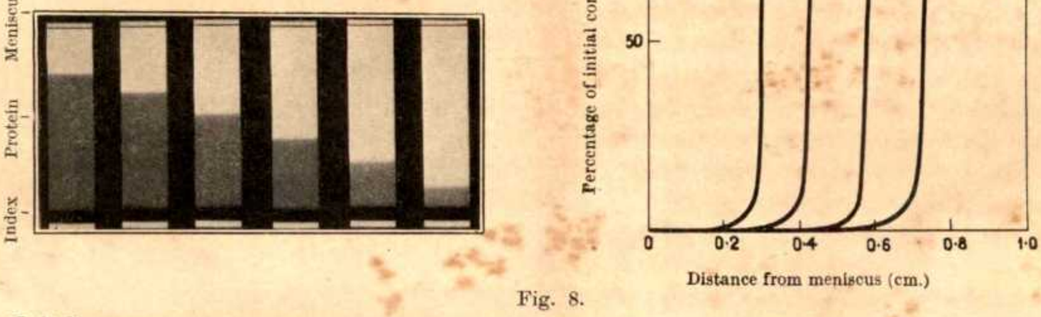

Fig. 8.

(*Left*) SEDIMENTATION PICTURES OBTAINED BY MEANS OF THE ABSORPTION METHOD ; AND (*right*) CURVES OF CONCENTRATION DISTRIBUTION FOR *Helix* HÆMOCYANIN at *p*H 5·5 ($M = 6{,}740{,}000$, $s = 98{\cdot}9 \times 10^{-13}$) ; CENTRIFUGAL FORCE 45,000 TIMES GRAVITY ; TIME BETWEEN EXPOSURES 5 MIN. THE SHARPNESS OF THE BOUNDARY AND STEEPNESS OF THE CURVES DEMONSTRATE THE HIGH DEGREE OF MOLECULAR HOMOGENEITY OF THIS PROTEIN (I.-B. ERIKSSON-QUENSEL[20]).

molecular state. The original molecule of weight 6,740,000 ($s = 98 \cdot 9 \times 10^{-13}$) dissociates step-wise into halves ($s = 62 \cdot 0 \times 10^{-13}$), eighths ($s = 16 \cdot 0 \times 10^{-13}$) and sixteenths ($s = 12 \cdot 1 \times 10^{-13}$). The *p*H-dissociation products represent perfectly homogeneous components[20]. The presence of divalent ions ($Ca^{\cdot\cdot}$, $Mg^{\cdot\cdot}$) causes a considerable change in the stability diagram of *Helix* hæmocyanin. Measurements of the Tyndall effect gave the first indication of this interesting phenomenon (J. Brosteaux[21]). An analysis by means of the ultracentrifuge (I.-B. Eriksson-Quensel) has shown that upon addition of 0·01 molar calcium chloride, the dissociation on the alkaline side of the isoelectric point does not become noticeable until a *p*H of about 9·5 is reached, where splitting of the molecule into halves and eighths takes place. Without $Ca^{\cdot\cdot}$ the dissociation starts already at *p*H 7·4.

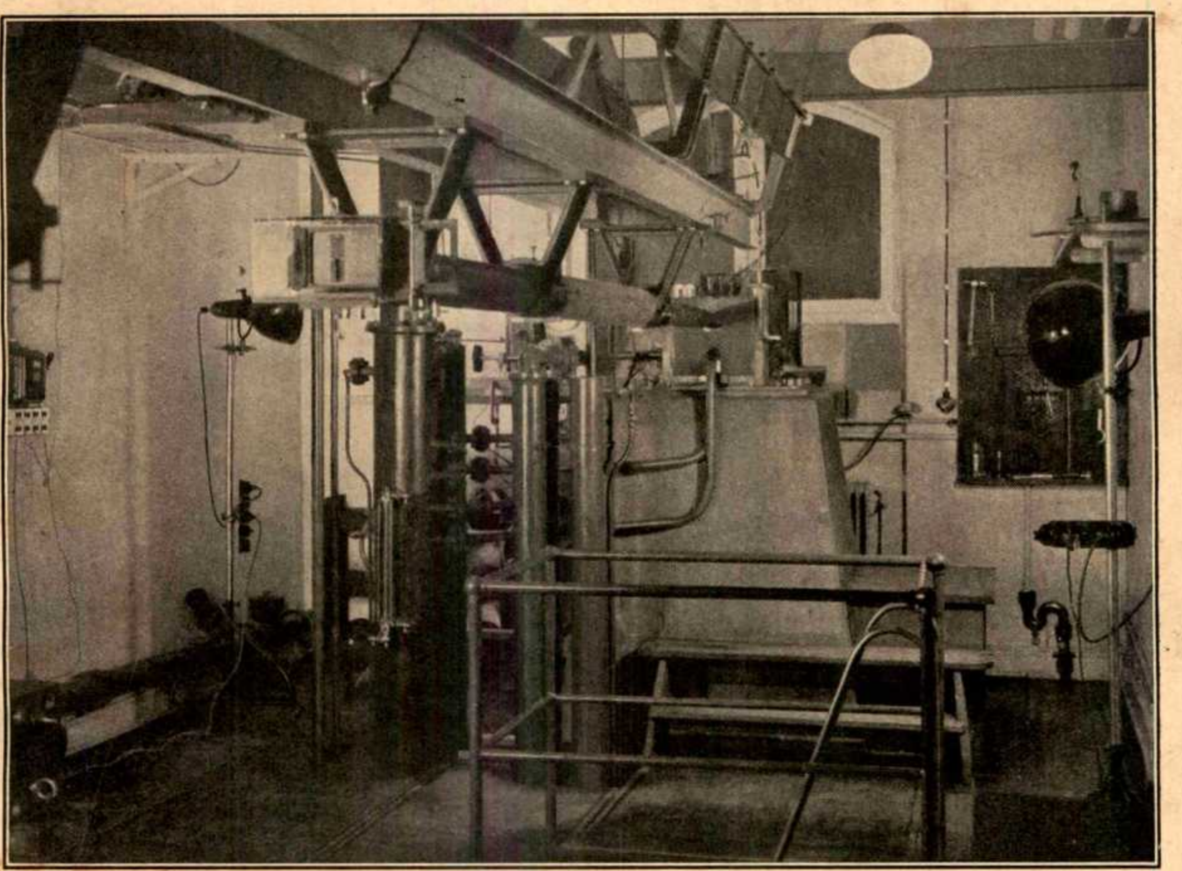

Fig. 9.

THE OIL-TURBINE ULTRA-CENTRIFUGE INSTALLATION.

The reversibility of the dissociation-association process influenced by hydrogen ion concentration is demonstrated by the following experiment. A solution of *Helix* hæmocyanin at *p*H 6·8 of sedimentation constant $98 \cdot 9 \times 10^{-13}$ (molecular weight 6,740,000) was brought to *p*H 8·0, where it contains three components with the sedimentation constants $98 \cdot 9 \times 10^{-13}$, $62 \cdot 0 \times 10^{-13}$, $16 \cdot 0 \times 10^{-13}$ (molecular weights 6,740,000, 3,370,000, and 842,000). The *p*H was then changed back to 6·8 and a sedimentation analysis performed. It was found that all the fragments of dissociation had completely united to form the original component of $s = 98 \cdot 9 \times 10^{-13}$ (molecular weight[20] 6,740,000).

High dilution often causes dissociation. Thus hæmoglobin is partly dissociated into half molecules upon dilution[29]. In dilute solutions of thyroglobulin there are present several dissociation products[23]. The addition of an amino acid or another protein often causes dissociation. Thus serum albumin may be split by adding clupein[42].

In certain cases even extremely small amounts of foreign substances may cause appreciable dissociation. Thus the addition of 0·001 per cent thyroxin gives rise to an appreciable dissociation of thyroglobulin (Fig. 15)[23].

The action of a dissociating compound on a protein is more or less specific. An amino acid which acts strongly upon a certain protein may have no effect on another protein, and vice versa.

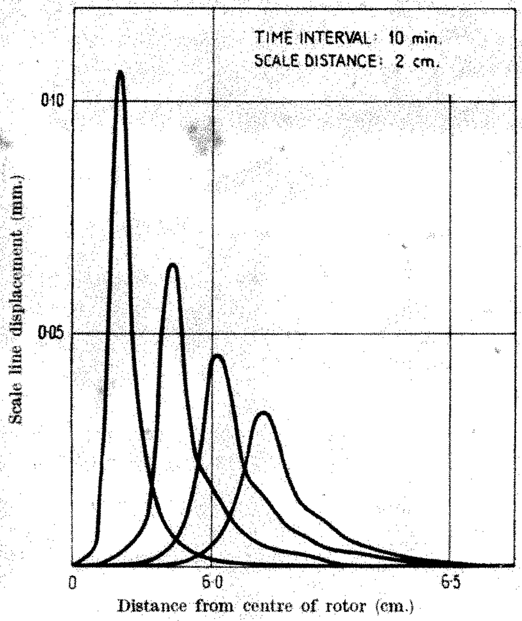

Fig. 10.

Sedimentation diagram obtained by means of the refractive index method from slightly denatured tobacco-mosaic virus protein at pH 9.5; centrifugal force 10,000 times gravity; time between exposures 10 min. (I.-B. Eriksson-Quensel [20a].

Thus arginin plus ammonium chloride dissociates serum albumin but not *Helix* hæmocyanin, while lysin plus ammonium chloride splits the latter protein but not the former. Guanidin chloride affects *Helix* hæmocyanin very strongly but has only a very slight effect on serum albumin. Clupein splits both, and arginin without ammonium chloride has no effect on either of them (K. O. Pedersen, I. B. Eriksson-Quensel).

High salt concentration may cause dissociation or association. In solutions of thyroglobulin ($s = 19{\cdot}2 \times 10^{-13}$; $M = 640{,}000$), the addition of 4 molar sodium chloride gives rise to a homogeneous association product of $s = 196 \times 10^{-13}$, corresponding to a molecular weight[23] of about 16,000,000.

The above survey has aimed at giving a general picture of the physico-chemical properties of the protein molecules, especially with regard to the influence of environment. In the following, a short summary of some of the results obtained in Uppsala for special groups of proteins will be presented.

The serum proteins are among those which have been most fully studied, but which still present notable difficulties. Serum albumin ($M = 67{,}000$; $s = 4{\cdot}5 \times 10^{-13}$) is found to be homogeneous both in sedimentation and electrophoresis. Serum globulin is complex. Molecules ($s = 7{\cdot}1 \times 10^{-13}$) of mass double that of serum albumin and reversibly dissociating into halves make up the bulk of it. Usually there is also present components of larger mass, among which the most prominent one has a sedimentation constant of 17×10^{-13} (v. Mutzenbecker[24], McFarlane[25]).

Fig. 16 shows the sedimentation pictures (*Schlieren*-method) for a pathological serum (amyloid-nephrosis) with three protein components clearly resolved and a fourth just beginning to show up at the meniscus.

In antitoxic sera the amount of globulin is very much increased. This rise in globulin content may be due to formation of molecules of the normal globulin mass ($s = 7{\cdot}1 \times 10^{-13}$) or molecules of mass corresponding to the sedimentation constant 17×10^{-13}. The former is the case with rabbit antibody globulin against pneumococcus type specific polysaccharides. The analogous horse antibody globulin is composed entirely of molecules sedimenting with the high constant (M. Heidelberger, K. O. Pedersen, A. Tiselius[26]).

The milk proteins are very complex and have not yet been completely disentangled. In cow's milk there are two albumins, the α-lactalbumin, of molecular weight 17,600 and sedimentation constant $1{\cdot}9 \times 10^{-13}$ and β-lactalbumin (also called Palmer's lactoglobulin) with $M = 39{,}000$ and $s = 3{\cdot}12 \times 10^{-13}$. Then there is a typical globulin of probably the double molecular weight, and several caseins[27].

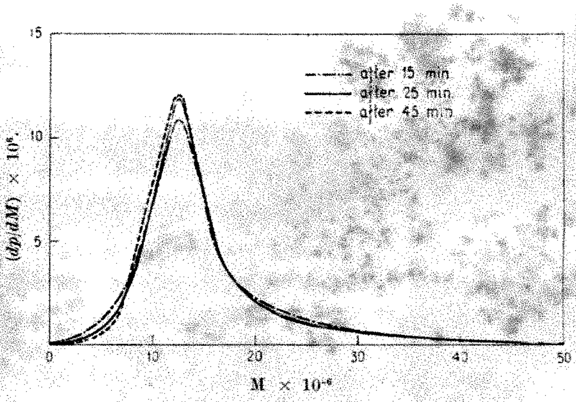

Fig. 11.

Molecular weight distribution curves for a slightly denatured tobacco-mosaic virus protein at pH 9·5 (I.-B.Eriksson-Quensel [20a]).

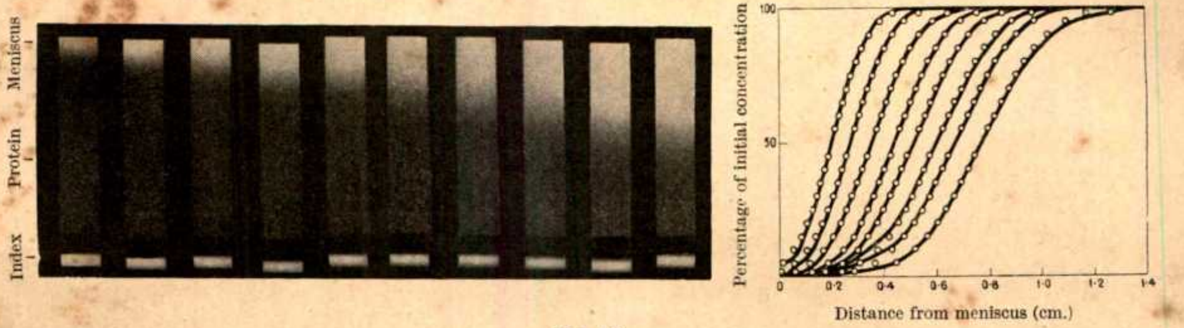

Fig. 12.

(K. O. PEDERSEN).

The respiratory proteins are of great interest not only because of their unique physiological importance but also from a physico-chemical point of view. With regard to the nature of the prosthetic group, these proteins may be divided into four groups; red pigments (erythrocruorins, hæmoglobins), green pigments (chlorocruorins), brown pigments (hæmerythrins), and blue pigments (hæmocyanins). The first three types contain iron, the last one copper.

One of the most striking points is the fact that low sedimentation constants, and therefore, comparatively small molecular weights are (with one exception) only found for pigments enclosed in blood corpuscles, while the respiratory proteins which occur dissolved in the plasma are characterized by high sedimentation constants and consequently by large molecular weights. The corpuscles of all the vertebrates, with the exception of the species belonging to the lowest class, the Cyclostomata, contain a pigment of the same molecular weight 68,000 (hæmoglobin) with four atoms of iron per molecule. The protein from the Cyclostomata corpuscles has a molecular weight one quarter of that of hæmoglobin, and certain invertebrates have corpuscle erythrocruorin of one half the hæmoglobin weight (A. Hedenius[10]). The mammalian hæmoglobin dissociates reversibly into half molecules upon addition of certain amino-compounds such as urea, acetamide, formamide (J. Steinhardt[29]). As shown by Anson and Mirsky, it is possible to resynthesize hæmoglobin from globin and hæme, and this synthetic pigment has proved identical with the native protein with regard to molecular mass. The isoelectric point is slightly lower and the chemical processes used seem, therefore, not to have left it entirely unchanged (N. Gralén). Erythrocruorins of high molecular weight occur in the blood plasma of the crustacean *Daphnia* ($M = 400,000$), the snail *Planorbis* ($M = 1,600,000$) and certain worms, *Arenicola*, *Lumbricus* ($M = 3,200,000$)[30,31].

The hæmocyanins form an interesting class with a number of inner connexions. The molecular

weights of the hæmocyanin molecules found in the blood of a certain species are always simple multiples of the lowest well-defined component. Thus for the Malacostraca the relationship is 1 : 2 and for the Gastropoda 2 : 8 : 16 : 24. Moreover, the weights of all the well-defined hæmocyanin molecules seem to be simple multiples of the lowest among them. In most cases the hæmocyanin components of a certain species are interconnected by reversible, *p*H-influenced dissociation-association reactions. At certain *p*H values a profound change in the number and percentage of the components take place. The shift in *p*H necessary to bring about reaction is not more than a few tenths of a unit. Consequently the forces holding dissociable parts of the molecule together must be very feeble[20].

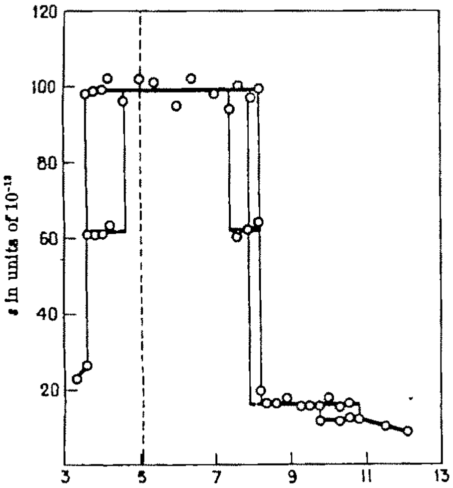

Fig. 14.

THE *p*H-STABILITY DIAGRAM FOR *Helix* HÆMOCYANIN; THE ISOELECTRIC POINT IS INDICATED BY THE DOTTED LINE (I.-B. ERIKSSON-QUENSEL[10]).

Not only the molecular weights of the hæmocyanins but also the mass of most protein molecules —even those belonging to chemically different substances—show a similar relationship. This remarkable regularity points to a common plan for the building up of the protein molecules. Certain amino acids may be exchanged for others, and this may cause slight deviations from the rule of simple multiples, but on the whole only a very limited number of masses seems to be possible. Probably the protein molecule is built up by successive aggregation of definite units, but that only a few aggregates are stable. The higher the molecular weight the fewer are the possibilities of stable aggregation. The steps between the existing molecules therefore become larger and larger as the weight increases. These statements are born out by the accompanying table (p. 1060), in which are collected recent data for the various constants of protein molecules as determined in Uppsala.

An examination of this table shows that the individual molecular weights within the groups differ considerably, but on the other hand it cannot be denied that a random distribution of molecular weights would give an entirely different picture. One might perhaps venture to compare

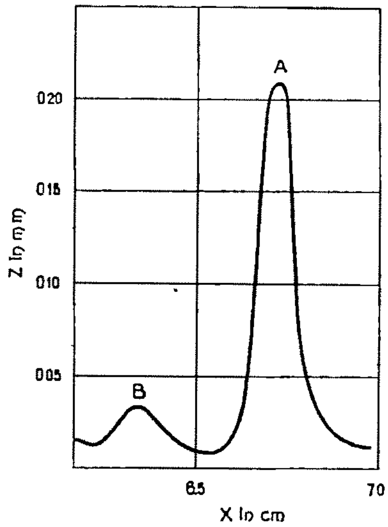

Fig. 15.

SEDIMENTATION DIAGRAM OF THYROGLOBULIN IN 0·001 PER CENT THYROXIN SOLUTION; THE RAPIDLY SEDIMENTING MAXIMUM, *A*, REPRESENTS NORMAL THYROGLOBULIN, *B* and *C* THE DISSOCIATION PRODUCT (H. LUNDGREN[11]).

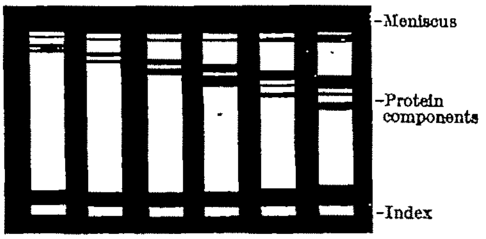

Fig. 16.

the regularities of this table with the whole number tendencies shown by the table of the atomic weights of the elements. In both cases there is an unmistakable regularity partly obscured by obvious deviations. As in the case of the periodic table of the elements, the underlying simple principle was not understood until quite recently (Aston's work on the isotopes); so perhaps the future will give us the key to a better understanding of the table of the molecular weights of the proteins and furnish the explanation for the regularities disclosed.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

Theory and Practice of Chemistry in the last Half Century"; Prof. R. V. Wheeler will read a paper on "The Problem of Dust in Coal Mines; and the Food Group will hold a symposium on "Fruit Juices", when papers will be read by A. Charley, Long Ashton Research Station, T. N. Morris, Low Temperature Research Station, Cambridge, and J. A. Reavell.

THE Eugenics Society has set up a Population Investigation Committee with Prof. A. M. Carr-Saunders as chairman and representatives from various societies, including one from the British Population Society, Mr. D. V. Glass acting as research secretary. He and Dr. C. P. Blacker have produced a pamphlet of thirty pages which discusses "The Future of our Population", issued by the Eugenics Society, 69 Eccleston Square, S.W.1, at the price of 6*d*. This introduces the subject on the basis of material supplied in the books of Carr-Saunders and Kuczynski, pointing out how present trends will affect future population decline. This is followed by a discussion of the reasons why families are being curtailed in the present generation, and ends with an appeal for financial support.

THE following appointments have recently been made in the Colonial Service: N. E. Davis, and W. G. Harper, forecasters, Meteorological Services, Bermuda; P. L. Mellier-Smith, inspector of mines, Malaya; H. O. Walker, European assistant, Meteorological Service, East Africa; A. G. G. Hill (senior geneticist, Department of Agriculture, Mauritius), director, East African Agricultural Research Station, Amani, Tanganyika; J. A. Cowan (pathologist, Penang), pathologist, Straits Settlements and professor of pathology, King Edward VII College of Medicine, Singapore; S. Bray (assistant inspector of mines), inspector of mines, Northern Rhodesia; A. D. Combe (field geologist), mining geologist, Uganda; K. A. Davies (field geologist), senior assistant geologist, Uganda; L. L. De Verteuil (late assistant agricultural officer, Leeward Islands), inspector of plants and produce, Gold Coast; A. E. C. de S. Gunasekera (assistant irrigation engineer), irrigation engineer, Ceylon; H. P. Rowe (district surveyor), chief surveyor, Survey Division, Lands and Mines Department, Tanganyika; F. G. Taylor (telegraph engineer, Railway Department), wireless engineer and broadcast officer, Sierra Leone.

PROF. OTTO HAHN, director of the Kaiser Wilhelm Institute for Chemistry in Berlin, has been made a corresponding member of the Bavarian Academy of Sciences.

PROF. A. CHEVALIER, professor of colonial agronomy in the National Museum of Natural History, Paris, has been elected a member of the Section of Botany of the Paris Academy of Sciences in succession to the late Prof. J. Constantin.

THE annual congress of the German Society of the History of Medicine, Natural Science and Technique will be held at Coblenz on September 3–6. Further information can be obtained from Dr. Artelt, Universitätsstrasse 3 b, Berlin, N.W.7.

A TRAFFIC clinic has recently been set up at Detroit for the elimination or improvement of dangerous drivers. Among the first hundred accidents studied, fourteen chauffeurs were too disabled to drive properly, seven were suffering from various psychoses and ten were mentally deficient.

THE twenty-fourth centenary of the birth of Hippocrates will be celebrated in the course of the summer by a cruise to Cos, Athens and Epidaurus organized by the Latin Medical Union, commonly known as Umfia. Further information can be obtained from Dr. Dartigues, Bureau de l'Umfia, 81 rue de la Pompe, Paris 16^e.

A CONGRESS of Medical Meteorology and Biometeorology will be held in Paris on July 4 under the presidency of Prof. Maurain, president of the Society of Medical Meteorology. Further information can be obtained from the General Secretary of the Society, Dr. Dujarric de la Rivière, 28 rue du Dr. Roux, Paris XV^e.

ACCORDING to the Central Statistical Department of the State Planning Commission of the U.S.S.R., the number of women employed in 1936 in the factories, in agriculture, transport, trade, public catering, health protection, education, etc., was 8,492,000, forming thirty-four per cent of the total number of employed workers. There were 15,338 women scientific workers, or little less than half the total medical practitioners in the country.

THE anti-noise campaign in New York, in which the Mayor, Mr. La Guardia, has taken an active part, began more than a year ago. In April 1936, the police issued 9,288 warnings, while summonses and arrests totalled 547. In May, legal enactments were adopted providing fees for offending. In November the police issued 15,661 warnings, and the number of arrests and summonses rose to 1,012. Motors continue to be the worst offenders, and radios come next.

THE Argentine Society for the Progress of Science awarded travelling fellowships during the year 1935 to Dr. Juan Carlos Speroni, to study the technology of wool in England, Dr. Santiago A. Celsi, for electrochemical investigations in the Institute of Physics and Chemistry at Madrid, and Dr. Jorge Thenon, to study psychiatry in Paris. In 1936 four more travelling fellowships were awarded respectively to Prof. Marcos A. Morinigo for studying American linguistics in Paris, Dr. Rodolfo Schwartz of Cordoba for the study of the bacteriology of tuberculosis and Dr. Ignacio Pirosky for the study of immunology at the Institut Pasteur in Paris, and Dr. Alberto Manso Soto for the study of bacteriology in England.

IN NATURE of May 29 a request was made for copies of NATURE for a boys' secondary school in London. Several offers have been received and the headmaster of the school informs us that his needs are now met.

Letters to the Editor

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1072.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Sidereal Time Periodicity of Cosmic Rays and its Phase Shift

WITH a coincidence apparatus—aperture in north-south direction 10°, east-west direction 40°—we have since July 1934 recorded continuously the intensity of the cosmic radiation (hourly records, sidereal time). The counters were arranged in the first series vertically one above the other, and later with 36 cm. lead between the counters in vertical position of the plane of the counter axes, and the plane inclined 24°, 50° and 64° towards the south. The material of the total number, 720 days of observation was subjected, after reductions for barometer and terrestrial magnetic field effects, to harmonic analysis, whereby we determined the time and the amplitude of the first harmonic wave. Arranging the time of the occurrence of the maximum in accordance with the total thickness of the absorbing matter, we get as a first approximation a straight line connexion (Fig. 1). The equation of the line of regression has the following form:

$$y = 29^{\text{h}}\,40^{\text{m}} - 0{\cdot}90\,E \pm 1^{\text{h}}\,10^{\text{m}}$$

(where E is the thickness of the absorbing material in metres of water), for the measurements in which the counters were filled with air (efficiencies about 27 per cent); and

$$y = 33^{\text{h}}\,4^{\text{m}} - 0{\cdot}94\,E$$

for counters filled with argon plus alcohol (efficiency about 95 per cent).

We are most probably confronted with a maximum, corresponding to a definite direction, and with its phase shift under the influence of the earth magnetic field. From the inclination of the line it can be deduced that negatively charged particles are involved in it.

The inclination of the line of regression for air-filled counters is nearly the same as for argon plus alcohol-filled counters, but is displaced sideways with respect to it. This is probably due to the argon plus alcohol-filled counter reacting in a higher degree upon the softer components. The circumstances that the maximum for directions so widely different fits so well a straight line relationship and, moreover, that the amplitudes are on the average nearly equal, suggest the conclusion that the wave is not caused by anisotropy in outer space (for example, a greater density of radiating matter away from the direction of the Milky Way) but that its source should be looked for in an effect of the galactic rotation pointed out by Compton and Getting[1]. In this case the time of the maximum for undeflected rays would be at $20^{\text{h}}\,40^{\text{m}}$ of the foregoing day. They have calculated the magnitude in the increase of the intensity, which one should expect for a coincidence apparatus through the increase in the number n of the incoming particles:

$$\frac{\Delta n}{n} = \left(\frac{1}{(1-\beta)^{3}} - 1\right) F\,,$$

where $F = \frac{1}{2}\,(\cos\varphi_{\text{max.}} - \cos\phi_{\text{min.}})$, ϕ is the angle between the observer's zenith and the direction of motion and $\beta = 0{\cdot}001$ speed of the motion. In our latitudes (47° 30′ N.) and with the inclinations used—if we neglect the deviation in the north-south direction caused by the earth's magnetic field—we find for the average value of F, $0{\cdot}6$; and hence for the amplitude of the wave to be expected, $\pm\,0{\cdot}18$ per cent. The experimental results, however, lead to a value of about $\pm\,0{\cdot}9$ per cent. This disagreement can probably be met by the following considerations. From our measurements of the diurnal variation[2], performed with the same counter arrangements, an increase in the horizontal intensity of the earth's magnetic field by 10^{-5} gauss involves a decrease in the intensity of the radiation of about $0{\cdot}06$ per cent. For every point along the path of any charged particle in the earth's magnetic field, the radius of the curvature is (for high energies) proportional to E/H, where E is energy of the particle, and H is intensity of the magnetic field. So long as the relative changes are small, the effect of the decrease of the magnetic field is identical with an effect caused by an increase in the energy of the incoming particle:

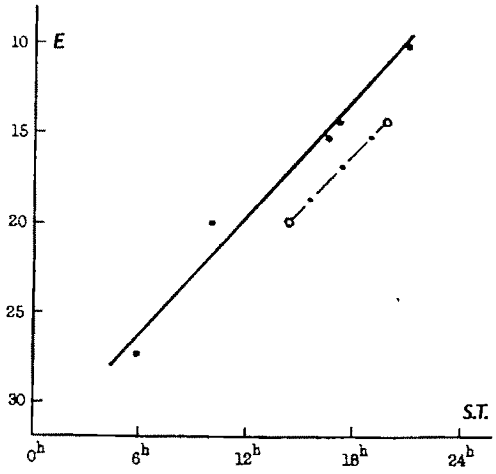

Fig. 1.

RELATION OF TIME OF THE MAXIMUM OF THE FIRST HARMONIC WAVE (SIDEREAL TIME) TO THE THICKNESS OF THE ABSORBING MATERIAL (E). SOLID CIRCLES FOR AIR-FILLED COUNTER, OPEN CIRCLE FOR ARGON PLUS ALCOHOL-FILLED COUNTER.

$$\frac{d(\Delta J/J)}{d(\Delta H/H)} = -\frac{d(\Delta J/J)}{d(\Delta E/E)} = -12\,; \quad \frac{\Delta J}{J} = 12\,\frac{\Delta E}{E}$$

due to the galactic-rotation effect the change in the energy is of the order $\frac{\Delta E}{E} = \frac{1}{1-\beta} - 1 = 10^{-3}$; so that the amplitude of the sidereal-time wave will be:

$$\frac{\Delta J}{J} \cdot F = 12\,\frac{\Delta E}{E} \times 0{\cdot}6 = 0{\cdot}7 \text{ per cent.}$$

Adding to it the expected amplitude according to the calculations of Compton and Getting (± 0·18 per cent), we get as a result an amplitude of about ± 0·9 per cent, in good agreement with the experimental values.

It should be mentioned that for other counter arrangements, or for an ionization chamber—since the sidereal time wave depends largely on the magnetic effect—the amplitude is as likely to be smaller as larger. By coincidence apparatus the predominant part of the amplitude is proportional to the magnetic effect; for harder rays (greater filtering) the magnetic effect will be smaller, and in accordance with it, the amplitude of the sidereal time wave should also be smaller; this conclusion seems to be detectable also in our measurements, as the amplitude in the direction 64° was only ± 0·5 per cent (but the deflection in the north-south direction should also be taken into consideration in determining the value of F). In the case of the ionization chamber, the diurnal variation[3], and hence the magnetic effect, is much smaller, so that here the effect calculated by Compton and Getting is predominant, and the sidereal time wave will have a much smaller amplitude.

The measurements were made through the kindly assistance of the Hungarian Council for Natural Science and the Széchenyi Scientific Society.

The Continuous β-Ray Spectrum

QUANTUM mechanics deals with object systems composed of only a few particles out of the total number of particles in the universe. The particles of the local object system, which may be an atom or atomic nucleus, are supposed to be incapable of dropping into vacant energy levels in the background consisting of the unspecified particles of the universe. Also an unspecified particle of the background is supposed to be incapable of falling into one of the vacant levels of the local specified system. As Eddington[1] has pointed out, this means that quantum mechanics *postulates* that the levels of the background are all below the ground-level of the local object system, and further, that all the levels in the background are occupied by one particle, a neutral scalar particle in Eddington's theory, in each level in accordance with the exclusion principle. The *limit* energy of the unspecified background particles corresponds to the *threshold* energy of the local specified system. The background forms a uniform isotropic 'comparison fluid' which is postulated by our statement of the quantum theory.

The disintegration β-particles are believed to arise from the transformation of a neutron into a proton and an electron inside the nucleus. In order to conserve spin and energy, since the β-particle spectrum is continuous, the existence of a neutrino has been assumed.

Let us suppose that a neutron in an upper energy level of the nucleus reverts to an unspecified particle of the background. To make room in the background for this particle, one of the unspecified background particles must be specified, and so it becomes a particle in the object system, that is, the nucleus. Let the background particle be specified as a proton in a lower energy level of the nucleus. The energy lost by the nucleus is now resident in the background and can be employed in raising an unspecified particle of the background to the limit energy (that is, the threshold energy of the object system), where it becomes specified as an electron and is endowed with kinetic energy equal to the energy change in the nucleus less the amount of energy required to raise the particle to the limit level.

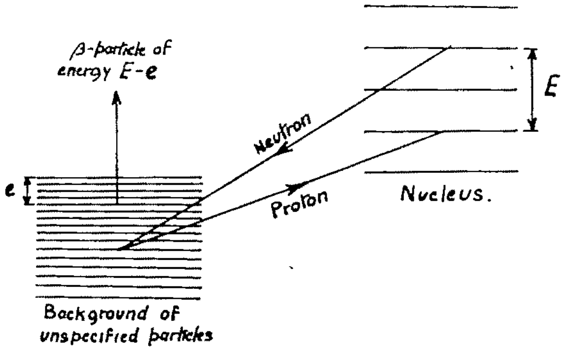

Fig. 1

Since the energy levels in the background just beneath the limit energy are practically continuous, for they have quantum numbers of the order of 10^{28}, the β-particle spectrum will be continuous. Since the electron comes from the background it will have the requisite spin. The process suggested above is shown diagrammatically in Fig. 1. It should be added that Eddington has shown[2] that the emission of an electron does not leave a vacant level in the background.

Supraconductors of Small Dimensions

MENDELSSOHN[1] has suggested that the high threshold value of supraconductive alloys and impure metals might be confined to regions of very small dimensions. In connexion with subsequent experiments[2], it was pointed out that for thermodynamical reasons there might exist a causal relation between small dimensions and high threshold value, and that supraconductivity might persist to a higher field strength in sufficiently fine wires than in the massive metal at the same temperature. This assumption is supported by results obtained in Toronto[3] on supraconductive films deposited on another metal. Owing to the possibility, however, that in this case the phenomena may have been influenced by the formation of an alloy at the boundary of the two metals, definite proof cannot be obtained by these experiments.

Conductivity experiments on fine lead wires in a longitudinal magnetic field at 4·2° K. have now been carried out. The specimens were made by the Taylor process from pure lead (99·999 per cent) and annealed. The largest diameter at which a change of threshold value (that is, the field strength at which the first resistance appears) was found is 14·2 μ. From this size downwards, however, the threshold value increased with decreasing diameter of the wire as can be seen from Fig. 1. In the smallest wire (5·6 μ) the threshold field exceeded the normal value by 4·08 per cent. Hysteresis phenomena were observed at the return to the supraconductive state.

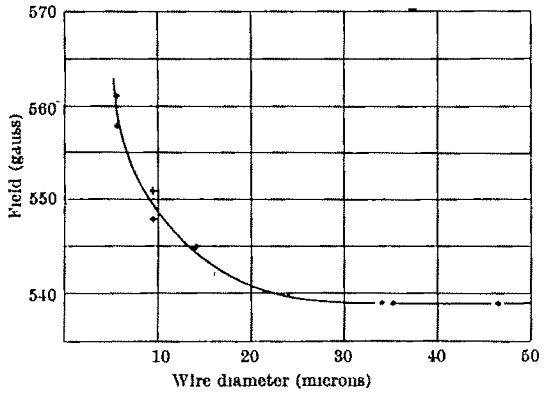

Fig. 1.

THRESHOLD FIELDS OF FINE LEAD WIRES AT 4 21° *K*.

This result shows that the depth to which a magnetic field penetrates a supraconductor at the surface cannot be neglected as soon as the size of the supraconductor becomes of the order of 5×10^{-4} cm., thus indicating a depth of penetration of the order of 10^{-5} to 10^{-4} cm. In connexion with the calculations of H. London[4], this would mean that the number of supraconduction electrons is of the order of Avogadro's number. However, more experiments, especially on the free energy of supraconductors, have to be carried out before definite conclusions concerning this last point can be drawn.

Sedimentation Equilibrium in the Simplest Air-driven Tops

IT has been highly desirable to develop a simple device everywhere available for accurately measuring sedimentation equilibrium of particles of all sizes from the smallest molecules in solution to the largest colloids or filter-passing organisms. We have used one method of limited scope throughout the past year for measuring the molecular weight of sucrose within 5 per cent in a one-piece hollow air-driven rotor[1].

We have more recently perfected for universal use a rotor consisting of two pieces of steel and a rubber sac in which is laid a pile of 100 ordinary annular washers of coin silver containing 10 per cent copper, and each 0·003 in. thick. The washers are alternately wide and narrow, the outside diameter being the same in all cases. They are held pressed together so that the liquid between the wide washers is immobilized in annular layers, 0·003 in. thick and several millimetres deep. Sedimentation equilibrium is set up in this immobilized liquid in any desired centrifugal field up to a few hundred times gravity.

However, the immobilized liquid is inaccessible. The simple device for studying it is to have a thin layer of excess liquid completely mobile and convecting, lining the cylindrical space within the pile of washers. This liquid is necessarily identical in composition with the most dilute portion of the sedimented liquid. Knowing the speed, the composition of the liquid originally put into the rotor, and the dimensions of the latter and of the washers therein, it is only necessary after the rotor is stopped to withdraw a sample of the supernatant mobile liquid for analysis in order to determine the molecular weight of any molecules or particles of uniform size. Sucrose has given a molecular weight 331 and 339 instead of the theoretical 342. Full details are being published elsewhere.

Another variant in design permits sampling of the liquid in contact with the outside radius of the immobilized liquid as well, to test whether the molecules of particles are all of one size.

Automatic Plotting of Electron Trajectories

AN apparatus developed independently in this laboratory plots trajectories of charged particles in potential fields entirely automatically. A similar scheme has recently been reported by Gabor[1], but the apparatus described below has certain differences and perhaps advantages.

The basic principle of both systems is the same; namely, the plotting of a trajectory by adjusting the radius of curvature at each point of the path to the value $2V/E_n$, where V is proportional to the total kinetic energy of the particle and E_n to the force acting normal to the path.

In the apparatus here, both these quantities are measured by an electrode unit consisting of two platinum wires 0·005 in. in diameter and spaced about 0·005 in. apart, the leads from which are connected to the primary of a specially designed shielded transformer. The centre tap from the primary goes to the input of an amplifier used for measuring V, while the secondary is connected to an amplifier which measures E_n. The probe is mounted on a carriage, shown in Fig. 1, which rolls on a piece of plate glass placed directly over the electrolytic tank. A rigid connexion between probe and carriage is formed by a U-shaped bar, one end of which is attached to the carriage, the probes being mounted at the other end, under the glass plate. The pencil is placed directly over the probes. This permits the probe and carriage to move over the entire area of the tank without being obstructed by the glass plate. The paper on which the path is to be recorded is laid on the glass. Moving parts are thus reduced to a minimum, the probes, while rigidly attached to the carriage, are always aligned so as to measure the gradient perpendicular to the trajectory, and the mechanical and frictional difficulties associated with pantographs and parallel links are avoided.

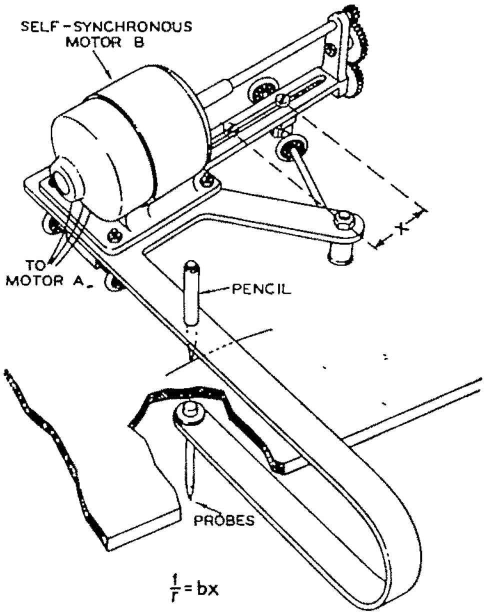

Fig. 1.

V and E_n are measured by null methods on Kohlrausch slide-wire potentiometers. An electric motor controlled by an amplifier is coupled to each potentiometer and adjusts it automatically to the null position. The accuracy of this automatic setting is approximately 3 parts in 10,000, which is higher than the overall accuracy of the system at its present stage of development. The quotient E_n/kV is obtained on a third automatically driven potentiometer using the circuits shown in Fig. 2. The displacement of the drumhead of the third potentiometer is translated directly to the movable axle of the carriage by means of a pair of self-synchronous motors, one coupled directly to the motor (No. 3) which drives the potentiometer, and the other mounted on the carriage, coupled to a lead screw which varies the displacement X. A method of accounting for initial velocity is indicated in the diagram.

The carriage itself is driven slowly (about 1 mm. per second) along the trajectory by a small electric motor. The process of plotting a trajectory is thus continuous and completely automatic.

The accuracy of the machine is at present limited by the measurement of E_n, which is in error by ± 1–2 per cent. A typical example of the present overall performance is the following: A uniform field was produced by applying 5 volts at 420 cycles between plane parallel electrodes 100 cm. apart in the electrolyte (water). A trajectory was traced starting at $V/V_0 = 0{\cdot}085$ (V_0 = total voltage across the tank), at such an angle that the predicted curve was $y = 1{\cdot}93x + 0{\cdot}138x^2$. The path actually drawn could be accurately represented by $y = 1{\cdot}91x + 0{\cdot}132x^2$ (x varied from 0 cm. to 13 cm.). A retraced path produced by moving the carriage back again deviated by 1·5 mm. from the original at the starting point. As the development is still in progress, these figures must not be regarded as final.

The significance of the constant k is of interest. $k = 1$ signifies that $Ve = \frac{1}{2} mv^2$, and $E_n e = mv^2/r$ in accordance with classical dynamics. If $k = 1$ the transverse acceleration is different from the classical value. Two cases of practical interest in which this is true are, respectively, motion in a transverse magnetic field, and motion at relativistic speeds. By properly adjusting the value of k during the description of a trajectory, either or both these conditions can be taken into account.

Phosphorus Metabolism in Normal, Rachitic and 'Treated' Rats

In a letter to Nature[1], Chievitz and Hevesy made a provisional communication on the use of radioactive indicators in the study of phosphorus metabolism in rats. In a recent paper to the Royal Society of Copenhagen[2], a detailed account of these investigations was given. Since 1936, we have been making experiments on phosphorus metabolism in normal, rachitic and 'treated' rats, utilizing also a radioactive phosphorus isotope as an indicator[3] Although the detailed figures will be published shortly in the *Proceedings of the Royal Academy* at Amsterdam, we think a brief review into our experiments may be of general interest.

In six series with about sixty rats, we tried to investigate the absorption, retention and deposition in bone of normal, rachitic and 'treated' animals. The 'treated' rats are those rachitic rats, which received a dose of halibut oil a few hours before the oral administration of the radioactive isotope.

In our experiments the 'labelled' phosphorus was administered as sodium phosphate in an aqueous solution of *p*H 6–7. For that purpose, in four series, a fixed quantity of the radioactive solution was inserted by an exactly calibrated pipette into the stomach of the rat through a small stomach tube. In the fifth and sixth series the radioactive solution was injected in the tail vein.

A certain time after the administration of the active sodium phosphate—in our experiments after 1, 2, 8 and 8½ hours—the rats were decapitated and then quickly sectioned. The œsophagus was ligatured near the pro-stomach, whereas the ileum was doubly ligatured close to the cæcum. Then the œsophagus was cut orally to the ligature, the ileum between the two ligatures. The limb bones were then dissected and cleaned, and the residue of the body with the head was collected. Now the preparations of the several organs to be measured were made. The determination of the radioactivity of the samples of blood, small and large intestine, fæces, urine, bones and residue was done with the compensation ionization chamber, whereby the ionization current produced by the radioactive preparations was compared each time with the ionization current of a constant source[4].

The first series of experiments, in which the rats were decapitated after one hour, showed that the blood in normal and rachitic rats contains scarcely any radioactive phosphorus, perhaps a little in the rachitic rats, whereas the skeleton contains sometimes a considerable amount. The 'treated' rats, on the contrary, contain a large quantity of the labelled phosphorus in the blood. The rapid entrance of the phosphorus isotope into the bone is perceptible as well in the normal and rachitic rats as in the 'treated' rats[3].

In the second series the rats were decapitated two hours after the administration of the active sodium phosphate. The radioactivity of the residue was also determined, and it was found that we could recover fully the whole of the quantity of the radioactive isotope administered. So our technique is reliable. But significant differences between the three groups of rats could not be found. The variation in the figures is too large to permit reliable conclusions.

Therefore in the third series the rats were decapitated after 8 hours, and here we think we can see small differences in the distribution of the labelled phosphorus in the body of the three groups. The deposition in normal rats averaged 55 per cent, whereas in rachitic rats the deposition of the active phosphorus averaged 75 per cent. These figures also show a large variation, so that we are convinced that many experiments are necessary to make a significant difference certain. This fact is clearly shown in the fourth series; the rats were decapitated after 8½ hours; but we could not confirm the results of the third series.

In the fifth and sixth series the active phosphorus was injected into the tail vein. Here it is to be noted that, one hour after the injection, a considerable amount of the labelled phosphorus could be detected in the small intestine.

Summarizing, we can say that the distribution in the organism of the active phosphorus could be followed up easily. Of the labelled phosphorus administered, nearly 100 per cent could be recovered in our experiments. Both by administration with the stomach tube, and by injection in the tail vein, a very rapid entrance of the active phosphorus into the bone was perceptible. Furthermore, it was observed that one hour after the injection into the tail vein, a considerable amount of the radioactive phosphorus was re-excreted into the small intestine. This re-excretion can only happen with the digestive juices, after the labelled phosphorus had been moved with the blood stream and deposited in the several organs. So far as the gross absorption is concerned, that is the difference between the quantity of phosphorus administered and the quantity present in the stomach and small intestine after a certain period, we could not see any difference in the period between 1 and 8 hours after the administration in the normal, rachitic and 'treated' rats. The same can be said about the re-excretion into the gut. A characteristic mode of action of vitamin D on the absorption or re-excretion into the gut from the administered phosphorus could not be demonstrated.

Œstrogenic Activity of *p*-Hydroxy Propenyl Benzene (Anol)

Following the publication of our letter in Nature of April 10, p. 627, concerning the high œstrogenic activity of anol, we have received information from some workers who have confirmed our observations, and from some others who have been unable to demonstrate activity with doses very much greater than those described by ourselves.

A re-investigation of the problem has indicated to us that some batches of apparently pure anol, melting point 93°, are highly active, whilst others are relatively inactive. Prof. W. Schoeller, of the Haupt Laboratorium, Schering Kahlbaum A.G., Berlin, has very kindly shown us his experimental results on this problem, and he has demonstrated that the mother liquor from chloroform crystallization of anol contains a highly active substance. We ourselves have repeated this, and by the distillation of material from the chloroform mother liquor have obtained a fraction which distils from this material at a temperature between 160° and 230° C. at 20 mm. and is highly active.

That this activity is not derived from some impurity in the inactive starting material (anethole), is demonstrated by the following experiment. Two grams of anol, which was completely inactive in doses of 10 mgm., was heated with alcoholic potassium hydroxide for 15 hours at 180°–200° C. After removing the alcohol, the alkaline solution was acidified and a brownish oil was precipitated which partly solidified at room temperature. From this crude product, it is possible to isolate a highly active fraction.

From this it would appear that the high activity originally described by us was due to some substance from the mother liquor and separating occasionally with the anol. The problem is extremely complex since large doses—for example, 100 mgm.—of all preparations of anol are active. This in itself is not surprising, since we have demonstrated that *p*-propyl phenol is active in doses of 100 mgm. It would appear, therefore, that there must be present in the mother liquor a substance of such a high degree of activity that its presence in some batches of anol is not sufficient to lower their melting point. The activity therefore of some batches of anol must be two-fold: first, an activity in the region of 100 mgm. per rat dose due to anol itself; and secondly, the very high degree of activity due to the presence of the unknown substance from the mother liquor. Anol polymerizes with the greatest of ease, and it is possible that the active substance is a polymer.

Production of Local Depressions in the Development of *Drosophila* Pupæ

IN a previous paper[1], which is now in the press, I have shown that the respiration of the pupæ of *Drosophila melanogaster* is depressed by carbon monoxide, and that the effect is, to a certain extent, reversible by light. (This latter fact may be interpreted as a dissociation, under the influence of light, of the chemical compound, which carbon monoxide forms with the iron-containing respiratory enzyme.) These findings make it possible to apply Runnström's device[2], which he used to obtain local inhibition of the cleavage process in *Ciona* eggs. The apparatus, constructed by Prof. J. Runnström, consists of a microscope with a strong condenser, through which a narrow beam of intense light can be focused on the stage of the microscope. If a living object is put under the microscope in a carbon monoxide atmosphere (for example, in a Carrel dish, filled with the suitable gas mixture), and part of it is illuminated with the beam, while the rest is kept shielded from light, its respiration should be more intense in the regions illuminated, than in the regions in the dark. Thus the apparatus is to a certain extent the reverse of the so-called ultra-violet point radiation, by which local defects can be produced with a narrow beam of ultra-violet light.

Following the suggestion of Prof. Runnström, the method was applied to developing *Drosophila melanogaster*. (The experiments were started in the Department of Experimental Zoology, University of Stockholm, and continued in this laboratory, where they are still going on.) After several unsuccessful attempts, it was found that early stage pupæ (less than 40 hours from pupation, when reared at constant temperature, 25° C.), in a suitable gas mixture (10 per cent oxygen and 90 per cent carbon monoxide), can be affected locally in their development by this method. Almost all external characters of superficial nature seem to be affected. If, for example, the treatment is applied laterally in such a way that one side of the pupa is illuminated and the other kept in the dark, the legs are found in some cases (if the treatment has begun early enough) shorter on the side kept in the dark. Similarly the wing is somewhat less pigmented and less advanced in growth (less folded), etc. The most striking differences are found in the bristles and in the colour of the eyes. The former are much shorter and often also deformed, as in the mutants 'stubble', or 'stubbloid'.

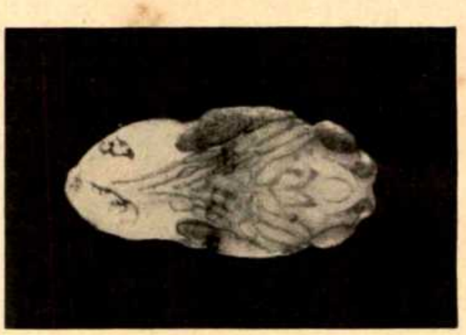

Fig. 1

Drosophila melanogaster. PUPA, SHORTLY BEFORE HATCHING, TAKEN OUT OF PUPAL CASE AND SEEN FROM THE VENTRAL SIDE. IT WAS TREATED ON ITS LEFT SIDE FOR 8 DAYS, FROM THE BEGINNING OF THE PUPAL PERIOD. NOTE SHORTER LEGS, AND BRISTLES, PALER EYE AND UNDERDEVELOPED WING ON THE TREATED SIDE.

The following data may serve as a preliminary example (lengths in μ, in brackets the controls, that is length of the corresponding bristles on the untreated side):

Orbitals: 60 (80), 45 (70), 60 (105), 105 (140), 45 (70), 25 (90), 45 (60).

Verticals: 105 (115), 30 (140), 125 (175), 80 (125).

Supra-alars: 80 (140), 35 (60), 115 (170), 35 (115), 70 (105), 45 (90).

Post-alars: 70 (105), 105 (140), 70 (105), 185 (285), 55 (80), 115 (130).

Dorso-centrals: 140 (200), 90 (140), 200 (250), 125 (140), 115 (160).

Scutellars: 160 (205), 140 (185), 275 (300), 230 (265).

The eye colour is always definitely paler on the side kept in the dark, and in this respect, again, the difference is especially striking when the treatment is begun soon after pupation (Fig. 1). Control experiments have shown that this result is not due to lack of light, because the same treatment applied in a normal atmosphere does not produce any differences in eye colour. Thus the effect must be due to the differential depression of cellular respiration in the tissues of the two respective eyes. In this connexion it is of great interest to note that the pigment of the *Drosophila* eye has been shown to act as a reversible redox-system, being colourless when reduced, and fully coloured when shaken with oxygen (cf. Schultz[3]).

The importance of the method for embryological experimentation seems to be that deficiencies are produced by a well analysed physiological treatment, instead of by the more crude method of killing or extirpating certain parts.

Lately the method has been modified. Instead of using one single beam, the whole dish, filled with carbon monoxide, was illuminated, and several pupæ were put in at once, but the pupal cases were first varnished at various places with a quick drying, thick black varnish, as used in blinding experiments on insects.

It is proposed to extend the studies to the histology of the treated pupæ, and also to earlier developmental stages (eggs), where they may give a welcome completion of the experiments of Geigy[4] with local ultra-violet treatment.

Genes for Dwarfing in Rice

THE typical dwarf varieties of rice vary in height from 10 cm. to 75 cm. They are characterized by shortened internodes, short and broad leaves and small compact panicles. Crosses of dwarf with normal varieties have generally shown that they are mono-recessive (Parnell[1], Akemine[2], Nagai[3] and Yamaguti[4]). Sugimoto[5], however, reports a dominant dwarf. Except for Akemine's work[2], there have been no attempts to determine the number of genes for dwarfing in rice. He crossed two dwarfs, differing in height, and obtained tall F_1 plants. In F_2 the segregation was 9 tall; 3 first type of dwarf; 3 second type of dwarf; 1 third type of dwarf; the last phenotype being the result of segregation.

Through the courtesy of rice workers in India, Japan, Australia and the United States of America, I obtained a number of dwarf varieties. These were crossed in various combinations with the view of determining the number of genes causing dwarfness. The studies have revealed that five genes are responsible in causing short stature. The various varieties are grouped below according to the existence of genes:

Gene.	Varieties.
d_1	Japan-I
d_2	Japan-II, Ratanghose, Kr-226, T-433, Mohmyaw, "Louisiana" and "California"
d_3	Kolamba-dwarf[6]
d_4	Y-2139
d_5	Bunketu-to

It will be seen that the gene d_2 occurs very extensively. The reactions of the various gene combinations are very varied.

The full results will be reported elsewhere.

Growth of *Lemna minor*.

IN view of the recent work on the growth and metabolism of *Lemna minor*[1], the following observations are of interest.

The multiplication of fronds in a colony of *Lemna* under favourable conditions has been regarded as exponential. While this conveniently expresses the growth of a *colony*, it does not express the rate of appearance of the daughter fronds from the individual 'mother'.

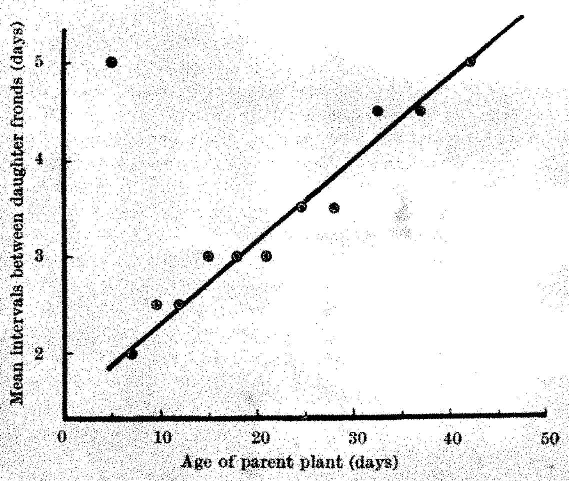

Fig. 1.

Under standard controlled conditions (full nutrient medium, illumination of 400 foot candles, temperature 25° C.) a frond produces 10–12 daughter fronds in succession. These appear alternately on two sides of the mother frond. The whole process takes 40–42 days; at the end of this time the mother frond dies. The mean interval between the appearance of successive daughter fronds is not constant.

The relation between rate of production of fronds and the age of the mother frond is illustrated by the accompanying graph (Fig. 1), on which the mean intervals between daughters are entered. Apart from the five-day period before the appearance of the first daughter frond, the observations lie on a straight line. The rate of frond production is therefore a hyperbolic function of time, and for the particular environment described above may be expressed by the equation:

$$r = \frac{1}{0\cdot089t - 1\cdot26}$$

where r is the rate, and t is time in days.

There is remarkable uniformity in the number of daughter fronds produced, the life of the mother frond, and the history of frond production described above. The effect of changes in the environment on the process is under investigation in this laboratory, and a fuller communication will be published in due course.

Neutrino Theory of Light

RECENTLY some doubts have been expressed about the neutrino theory of light, and Fock[1] has claimed to have found some general rigorous arguments against the possibility of such a hypothesis, especially in its existing form. We believe that Fock's arguments are not valid, though it seems that Jordan's original work[2] on the derivation of the photon amplitudes $b(k)$ from neutrino amplitudes, $a(k),c(k)$ is somewhat ambiguous, as it contains in fact an indefinite expression of the type $\infty - \infty$; later, Jordan proved the convergence of the result but in a somewhat artificial way.

We wish to remark that all these difficulties can be avoided at once by using the following expansion for the neutrino wave functions satisfying the one-dimensional Dirac equation:

$$\psi(x,t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} \Big[A_\varrho(k) \exp(-ic|k|t + ikx) + C^*_\varrho(k) \exp(ic|k|t - ikx) \Big] \, dx$$

where $A_\rho(k)$ and $C_\rho(k)$ are readily found to relate to *neutrino* and *antineutrino* respectively[3]. These Fourier coefficients are expressed through independent amplitudes $a(k)$, $c(k)$ obeying the Fermi commutation rules $a^*(k')a(k) + a(k)a^*(k') = \delta(k' - k)$, etc.

For the photon wave, we take the analogous expansion from the well-known paper of Dirac[4] with the coefficients $b(k)$ satisfying the Bose commutation rules:

$$b(k')b^*(k) - b^*(k)b(k') = \frac{ch}{2|k|} \delta(k' - k).$$

Now, we can easily proceed to the construction of the Bose amplitudes $b(k)$ from the Fermi amplitudes $a(k),c(k)$. For this, we consider the absorption of a photon as due either to the absorption of a neutrino and antineutrino of frequencies $(k - l)$ and (l), respectively, or as due to the absorption of a neutrino (antineutrino) of frequency $(k + l)$ and to the simultaneous emission of the same particle of frequency (l) (Jordan's neutrino Raman effect without change of direction). In this way we find:

$$b(k) = \frac{1}{k}\sqrt{\frac{ch}{2}} \left[\int_0^{\infty k_1} a^*(l)a(l+k)\,dl - \int_0^{\infty k_1} c^*(l)c(l+k)\,dl - \int_0^k a(l)c(k-l)\,dl \right].$$

($k = k/|k|$ defines the sign of the upper limit) where usually one takes all states above a certain one as unoccupied[5].

With $b(k)$ constructed analogously, one immediately verifies the required Bose commutation rules for $b(k),b^*(k)$ and thus proves the validity of the neutrino theory in a quite straightforward way. Apparently, Fock obtained his result by using, for the wave function, insufficiently general Fourier expansion.

A Lead Extrusion Phenomenon

DR. DUNSHEATH has referred[1] to the presence, in polished and etched sections of lead cable sheathing, of radial lines which pass through the crystals. It was held as one possible explanation that segregation of dissolved oxide might be responsible.

The presence of similar, but more pronounced, lines has frequently been observed in etched sections cut through lap welds in lead sheet. The appearance of such lines is shown in the photomicrograph (Fig. 1), and it is deduced from their position and direction that they coincide with the surfaces of successive layers of cast metal with which the weld was built up. As each layer solidifies, a surface skin of oxide is formed; this skin forms the base of the next layer and it is suggested that some oxide is taken into solution during the application of the welding flame each time fresh metal is added. The heat applied is so local and solidification so rapid that any oxide taken into solution would only diffuse to a minor extent.

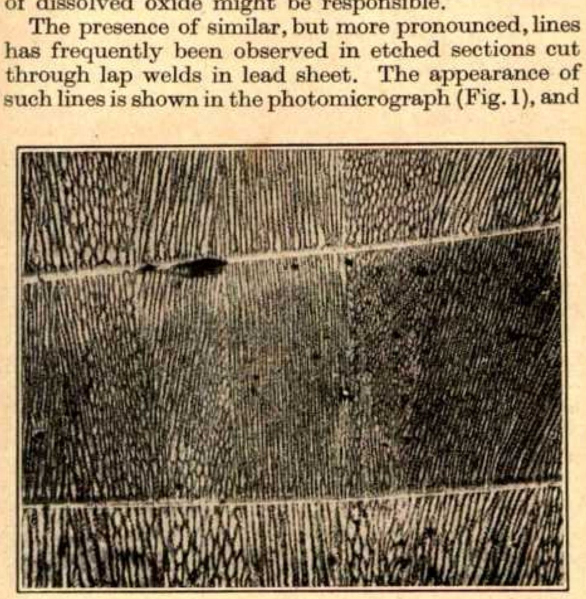

Fig. 1.

× 40 DIAMETERS.

The coring effect shown in the photomicrograph is due to the small amounts of impurities present in the particular lead illustrated.

Calcium Iodate as a Temporary Preservative

FOR the past two years we have been using a 0·1 per cent solution of calcium iodate as a temporary preserving agent for class material. The iodate is dissolved in distilled water and warmed to ensure thorough solution.

We find it particularly valuable for material to be preserved in a fresh and pliable condition from one practical class to the next. With the exception of Arthropods, it will keep any comparatively small object fresh and odourless for two to three weeks, and we have kept specimens of *Heterosepiola*, *Rana* and *Bufo* for six months. At the end of that period, the flesh of all specimens was soft and pliable, though slightly brown, and in *Rana* and *Bufo* the blood was still red in the arteries. Results with dogfish have not proved successful for a period longer than ten days.

Points from Foregoing Letters

BY subjecting to harmonic analysis the hourly records of the intensity of cosmic rays observed over a period of two years by means of 'counters' inclined at various angles to the horizon, Drs. J. Barnóthy and M. Forró find that there is a straight line relation between the maximum of the first harmonic wave (sidereal time) and the total thickness of the absorbing material through which the cosmic rays have passed. They consider this effect to be related to the galactic rotation.

From considerations of energy interchanges between an atomic nucleus and the universal 'background', Dr. F. L. Arnot concludes that the continuous beta-ray spectrum (the emission of electrons of varying energy by radioactive substances) can be explained without assuming the existence of undetectable neutrinos.

A graph showing the dependence of the threshold value of supra-conductivity (field strength at which resistance appears) in thin lead wire at 4·2° K. is given by B. Pontius. A change in threshold value was first noticed at 14·2μ diam., and the effect reached a value of 4 per cent in excess of normal at 5·6μ diam., indicating a depth of penetration of 10^{-5}–10^{-6} cm. for the magnetic field.

Prof. J. W. McBain and C. Alvarez-Tostado give a brief description of a simple 'rotor' for ultracentrifuging solutions of pure substances such as sugar in order to determine their molecular weight. It consists essentially of a pile of very thin (0·003 inch) silver washers, alternately wide and narrow, pressed together so that the liquid between the wide washers is imprisoned in anular layers. This enables the central core of liquid to be withdrawn and analysed after centrifugation.

An apparatus is described by D. B. Langmuir which draws the trajectories of charged particles in potential fields continuously and entirely automatically. Methods of accounting for initial velocity, transverse magnetic fields, and relativistic change of mass are described, and data illustrating the precision are presented.

The influence of vitamin D on phosphorus metabolism in normal and rachitic rats has been the object of a series of experiments made by Dr. M. J. L. Dols and Prof. B. C. P. Jansen in collaboration with Prof. G. J. Sizoo and J. de Vries. A radioactive phosphorus isotope was used as an indicator. In all the experiments a very rapid entrance of the labelled phosphorus into the bones was perceptible. One hour after the injection of the active phosphorus into the tail vein, a considerable amount was re-excreted into the small intestine.

Further experiments on the œstrogenic action of *p*-hydroxypropenyl benzene (anol) indicate, according to Prof. E. C. Dodds and W. Lawson, that while the pure compound has in itself a certain activity when given in large doses, the very high activity shown by certain specimens in small amounts is due to an unknown substance, probably a polymer of anol.

A. A. Wolsky finds that by means of partial illumination in a carbon monoxide atmosphere, local depressions in the development of *Drosophila* pupæ can be induced in the regions which are not illuminated. It is believed that the respiration of the pupæ is depressed by carbon monoxide, but illumination diminishes the effect, possibly because the chemical compound, formed between carbon monoxide and the iron-containing respiratory enzyme, dissociates under the influence of light.

By crossing a number of varieties of dwarf rice plants from India, Japan, Australia and the United States of America, B. S. Kadam has been able to determine that five genes are responsible in causing short stature.

E. J. Winter points out that although growth in a colony of a duckweed, *Lemna minor*, is exponential, yet when the individual frond is considered this is not the case. The rate of production of daughter fronds from a parent frond is shown to be a hyperbolic function.

A. Sokolow submits equations to overcome the difficulties raised by Fock in connexion with the new neutrino theory of light.

Brinley Jones submits a photomicrograph to support his view that the lines observed in etched sections cut through lap welds in sheet lead are due to a surface skin of oxide on each layer of metal used in building up the weld.

Research Items

Archæological Exploration in Peru: Cañete Valley

IN a third report on the results of an archæological expedition to Peru for the Field Museum, Chicago, in 1925 and 1926, Prof. A. L. Kroeber describes (*Anthropology, Memoirs, Field Museum, Chicago*, **2**, 4) excavations at Cerro Azul and Cerro del Oro, in the valley of Cañete, a large valley, as Peruvian coastal valleys go, but containing no town of much importance. The Cañete River, which has a large catchment area, maintains a considerable flow in all seasons, and the valley contains a number of well-known groups of ruins. Of the two sites under investigation, Cerro Azul is an imposing cluster of pyramidal ruins set immediately at the back of the modern port of Cerro Azul. Only one culture is represented here, belonging to the Late period, more or less synchronous with the Inca dominion, though no doubt partly antedating it. It is very similar to the Late Chincha culture, previously described by the author and other investigators. The Cerro del Oro is a nearly free-standing hill about four kilometres inland. It is connected by a low saddle with hills beyond, but otherwise is surrounded by ditches and cultivated lands. San Luis, a kilometre to the south-east, may represent an ancient settlement of which the inhabitants used the hill for their cemetery. It contains no remains of a non-funerary character. Many thousands of burials represent two cultures. One is the Late Cañete culture; the other, here provisionally called Middle Cañete, is shown to be earlier by its stylistic affiliations and by an established stratification. The Middle Cañete culture is characterized by skulls deformed fronto-occipitally, structures of small cubical hand-made adobe, a scarcity of metal, and by pottery and textiles, which show some Nasca influence, but no direct Tiahuanaco influence. The Nasca elements in the pottery are of Late Nasca type. On the other hand, there are occasional elements which suggest later Peruvian styles of the coast, Late Ica especially. While it has distinctive stylistic elements, the Cañete Middle is post-Early and pre-Late chronologically; but the absence of Tiahuanaco elements makes chronological correlations with other Middle period cultures uncertain.

Horned Ruminants of North America

THE deer, antelopes and other horned ruminants now existing in North America are few in number and give no hint of the vastness of the fauna inhabiting the continent in Tertiary and Quaternary times, of which they are the veriest remnant. This is brought out with great effect in the monograph on the horned ruminants of North America by Childs Frick (*Bull. Amer. Mus. Nat. Hist.*, **69**, 669, 103 text figures; 1937), a worthy companion to the similar volume previously published on Siwalik fossil deer and antelopes. The evidence upon which the account is based consists of more than 7,000 fossil skulls or parts of skulls, horns and limb bones. Most of the still-existing forms have been identified in the superficial deposits of the Ice Age, but so far only the prong-horn and deer groups have been found in the much older deposits of Late and Middle Tertiary. Even in glacial deposits, however, the modern types are associated with distinctive species which must have become extinct long before the advent of white races to America. It is difficult to account precisely for the impoverishment which has taken place since the great assemblage of the Tertiary fauna, but changes in topography and climate, accompanied by the shifting of faunas and the ravages of predators of both the animal and the plant world have played a great part. To these in latter days the destructiveness of man has been added, and the preservation of the remnant of a once magnificent and diversified fauna now lies in his hands.

Biological Races in Fruit-Flies

IN the *Canadian Journal of Research*, **15**, Sec. D, March 1937, Mr. A. D. Pickett gives an account of an investigation of the biological and morphological relations of certain species of flies belonging to the genus *Rhagoletis* of the family Trypetidæ. The author concludes from his observations that the practice of separating species on the basis of very slight morphological characters, which may all be the result of influences exercised by the particular plant host in which any such species has developed, is open to criticism and of doubtful soundness. The forms of the genus in question, which develop in apple, hawthorn and blueberry, were studied extensively with the view of ascertaining their relations to their hosts. The conclusion is reached that one species, namely, *Rhagoletis pomonella*, is involved, and that the female insects show a decided preference for laying their eggs in the plant host in which they themselves have developed during the larval instars.

Anatomy of the Carpel

DR. MABEL S. FRASER has recently published a very thorough study of the vascular supply to the carpels in the follicle-bearing Ranunculaceæ (*Trans. Roy. Soc. Edin.*, **59**, Pt. 1, 1936–7). This study brings into prominence the variations in the vascular supply not only in the different genera but also within the individuals of the species, and shows that caution is necessary in attaching wide evolutionary significance to isolated facts of anatomy. She adduces evidence of a carpellary trace of five vascular strands in many genera, as *Caltha* and *Trollius*, two strands running between midrib and marginal strands, and concludes that the primitive carpel may have been a palmately veined structure with a five-trace supply. The secondary vascular supply in the carpel wall varies widely within the species, but in the majority of genera it arises as a branch system from the marginal veins. In *Trollius* and *Caltha* there is variation in the vascular supply to the style which, in one gynæcium, may be provided by midrib or marginal bundles or both. On the whole, the author's position brings her near to the interpretation of the carpel advanced by Prof. A. J. Eames, but the paper is valuable for its wealth of anatomical data and the conservative and cautious treatment they receive. The author concludes that our knowledge of the putatively primitive angiosperm only suffices to show "the tremendous gap in our knowledge of the probable primitive Angiosperm from which our present-day carpel arose".

Cytology and Genetics of Cotton

A FURTHER study of the chromosomes and their pairing in various hybrids of *Gossypium* has been made by Dr. A. Skovsted (*J. Gen.*, **34**, No. 1). He concludes that the results confirm the division of the genus into three groups: (1) the cultivated New World cottons and certain wild species from America and the Pacific Islands, with $2n=52$ chromosomes; (2) wild species from America and the Pacific Islands having $2n=26$; (3) species from Africa, Asia and Australia, all having $2n=26$. In hybrids between members within each group the chromosome pairing in meiosis is almost normal. In hybrids between groups (2) and (3) the conjugation was incomplete and variable, while hybrids between members of (1) and (2) generally showed 13 bivalents and 13 univalents. From these and other results the inference is drawn that the genus *Gossypium* is monophyletic, with an early separation between the American and the Old World diploids. The New World tetraploids are believed to have originated from a hybrid between Asiatic and American diploid species. From the secondary pairing in American wild species, it is suggested that 13 is a secondary polyploid number from 6, five chromosomes being duplicated and one triplicated. In the same journal, Dr. S. C. Harland has investigated the inheritance of red petal spot in a series of *Gossypium* hybrids. By successively back-crossing plants of *G. purpurascens* heterozygous for spot with a spotless *G. hirsutum*, the spot was progressively weakened in the segregates and the tendency of the spot gene to show somatic and gametic mutation was greatly increased. From these and similar results it is concluded that the species of cotton may possess a complex of modifiers, the general effect of which is to preserve the stability of the genes and prevent them mutating at an excessive rate.

Distribution of Deep-Focus Earthquakes

MR. S. YAMAGUTI has made an interesting study of the distribution of 241 deep-focus earthquakes recorded in the "International Seismological Summary" for the years 1919–30 (*Bull. Earthq. Res. Inst.*, **15**, 170; 1937). The epicentres are plotted on a map of the world, and four lines are drawn in various regions surrounding those in which the focal depths are greater than 700, 500, 300 and 100 km. The regions of very deep foci are near Japan, in the middle of South America, the southern part of the Philippines, and the ocean east of Australia. On the Mediterranean coast, deep-focus earthquakes do not exist, while in North America they are rare. By projecting the foci of those in South America on a vertical plane containing the equator, the points obtained tend to lie on a zone through the middle of the continent and inclined towards the Pacific with a slope of one in five from the horizontal.

Troublesome Radio Echoes

IT is well known that radio signals passing between two points on the earth follow great circle paths, the radio energy being confined only by the earth and the ionosphere. There are two directions that a radio signal can take in passing from London to New York. One path extends westerly in the great circle plane and the reverse path extends easterly. As the latter has much the longer distance to travel, it arrives later, and may interfere with the former, causing an 'echo'. Short-wave transmission over long distances depends largely on the reflection of the waves between the earth and the ionized layer high overhead. In a paper by A. C. Peterson on "Around-the-World Radio Echoes" published in the *Bell Laboratories Record* of March, an account of the difficulties that radio engineers have to overcome is given. The altitude of the reflecting layer varies from 60 miles to 150 miles in height. The reflecting behaviour of this layer depends both on the frequency of the waves and on the exposure of the layer to light from the sun. When the layer is in darkness, frequencies greater than 10,000 kilocycles are generally not reflected and so transmission is poor. When the layer is illuminated, these waves are reflected and long-distance communication becomes possible. Observations show that the average intensity of the echoes varies in about the same way as the percentage illumination at different seasons of the year. Owing to the long round-the-world path, the echoes are considerably attenuated, and so a double or a treble echo is difficult to observe. Oscillograph records are given which show the echo plainly. The echo signal is rarely found to have a serious effect on the intelligibility of fixed carrier radio-telephone circuits.

Finite Elastic Deformations

IN the classical theory of infinitesimal deformations a fundamental principle (Hooke's law in its most general form) is equivalent to the statement that, in a virtual displacement of the strained elastic medium, the virtual work of all the forces, both surface and body, acting on the medium, may be obtained by integrating over the medium the scalar product of the stress tensor by the variation of the strain tensor. F. D. Murnaghan (*Amer. J. Math.*, **59**, 235; 1937) shows that this principle is merely an approximation, valid in the infinitesimal theory, but not valid in the finite theory, in which the variation of the strain tensor must be replaced by the space derivative of the virtual displacement vector. Fortunately the exact equations for an isotropic solid are sufficiently simple to yield numerical results, which the author compares with the experimental data obtained by P. W. Bridgman, showing a remarkably close agreement. A treatment of the Young's modulus experiment gives a qualitative explanation of the yield point phenomenon, which cannot be explained by the classical theory.

Is τ Tauri a Double Star?

MR. BERTRAND M. PEEK has published a short paper (*J. Brit. Astro. Assoc.*, **47**, 6, April 1937), with the title, "Occultation of τ Tauri". On January 22 he observed that the star was occulted with a succession of flickers, the process lasting about 0·4 second. On referring to his notes of February 1929, he found that he recorded the star as going out in two stages. He suggests that it is a double star, the separation not being less than 0·2″. It is worth noticing that Mr. G. F. Kellaway at Yeovil saw a similar phenomenon with this star on January 22, a fainter star continuing to be visible at least 0·5 sec. after the observed time of disappearance. Mr. Peek points out that the star will not be occulted in Great Britain before 1947, but a series of occultations will occur in the southern hemisphere until the end of the present year, and observers are asked to pay particular attention to the manner of disappearance.

Rockefeller and Philanthropy

By Willard Connely,

Director of the American University Union in London

THE life of John D. Rockefeller, who died on May 23, was a history of system, not only in the American business of oil, but also in the American business of philanthropy. Whilst Rockefeller was learning how to accumulate money, he was concurrently learning methods by which he should in time give it away. The nearer he approached monopoly, the easier it was for him to retreat to charity. It is because of Rockefeller's skill in the ways of corporations, in planning, shaping and extending them, that the vast 'benevolent trusts' which he created, trusts operated by business men as able as the executives of Standard Oil a generation ago, have become a model of American philanthropic enterprises to-day. That model has stood for 'efficiency in giving'.

These trusts admittedly share leadership in kind with the great Carnegie funds, which originated at almost the same time near the turn of the century. But Rockefeller early set an example to his eminent associates—Harkness, Archbold, Flagler, Folger—in giving money to the public cause. When still other capitalists devised similar charities, capitalists who in the era which Rockefeller dominated had like himself learnt from business the principle of consolidation, there ensued that rise of American philanthropy which has left few corners of the world untouched.

Shortly after the Rockefeller family moved west (1853) from New York State to Cleveland, Ohio, their son, aged about sixteen years, left school, to become a clerk at 4 dollars a week (16*s*.). Even then he began his lifelong practice of giving. He used to give dimes (5*d*.) to poor children worth helping. Of every such item Rockefeller kept a record; his meticulous juvenile notebook, which he called 'Ledger A', shows even the deposit of a penny at church. Establishing a commission firm of his own at nineteen years of age, he soon admitted partners, who multiplied his profits. There was in Cleveland an infant industry, the refining of petroleum. Rockefeller saw that if he could get a start in this business, he could make use of the competing transport facilities which Cleveland offered by both rail and water to distribute the oil widely at low cost. By the time he was twenty-eight he had formed the company of Rockefeller, Andrews and Flagler, and had bought a large oil refinery. Three years later, though his personal fortune was only £10,000, Rockefeller brought into being the Standard Oil Company, capitalized at £200,000. In another five years he had made his first million pounds. He was thirty-six years old. The rest of the story—the Oil Trust, its dissolution in 1892, its renewed prosperity as a New Jersey corporation, its second dissolution in 1911—is the story as well of the growth of Rockefeller's millions to the point at which he believed he could engage in effective and continuous philanthropies.

In planning his gifts, Rockefeller relied for many years on the advice of the late Frederick Gates, his intimate friend. One result of their collaboration was to place the disposal of capital as well as interest entirely in the hands of self-perpetuating trustees. In this respect the Rockefeller charities differed from other great American foundations. If the trustees decided to liquidate a trust, they could give all the capital away and discontinue the fund. This was recently done in the case of the International Education Board. The policy of Rockefeller in allowing absolute discretion to his trustees has been followed by his son, who although one of the trustees, casts only one vote.

Founding his first great benefaction in 1901, ten years before he retired from the presidency of Standard Oil, Rockefeller, while still in the business of accumulating, was able to apply his experience to the business of giving. This first trust was the Institute for Medical Research. He gave it a hospital in New York, and laboratories in New York and in Princeton (New Jersey). Such names as Flexner, Carrel and Noguchi are sufficient to remind one of the quality of work carried out, which has included the discovery of the anti-serum for cerebro-spinal meningitis, and the development of a serum for yellow fever, now in wide use in the tropics, especially by aviators. Huge sums have, of course, been expended as well on the study of cancer, infantile paralysis, and other diseases the mysteries of which are not yet fully solved.

The second trust, created by Rockefeller a few years later, was the General Education Board, designed to assist American universities. Rockefeller from the start had been anxious to help the Negro, particularly in medical education, and the Board contributed heavily to the medical schools of Negro universities in the South: Howard University, in Washington; Maharry Medical College of Fisk University, Tennessee; and Dillard Medical School in New Orleans. But on a wider scale, one of the signal appropriations of this Board was £2,000,000 for medical schools in general, to ensure a high quality of clinical instruction; schools which specially benefitted from this fund were those of Harvard, Yale and Columbia in the east, Johns Hopkins and Vanderbilt in the south, and Chicago and Iowa in the west. Having given medicine this great lift up, the Board turned to the basic sciences, physics, chemistry, biology, and in like manner established them on a sounder footing of research and teaching in important American university centres. Yet perhaps no grant of the General Education Board has been more welcome than the distribution of another £2,000,000, just after the Great War, to endow and increase salaries in all departments of higher education. The scheme was to match dollar for dollar, though in some cases the scale was one dollar to two, and in still others one to three. Graduates rushed to the call. Under this scheme, 170 American colleges large and small received grants, which needless to say have gone far to transform the quality of their staff.

In 1909 the third trust, the Rockefeller Foundation, came into being, a £20,000,000 corporation, with the world as its field of effort—"for the well-being of mankind". The Foundation has co-operated with

Governments of many countries to combat, for example, hookworm, malaria and yellow fever; and at the same time to institute centres of public health, to promote nursing education, and to develop medical schools. An instance of significant medical benefaction has been the support in large part of the Peking Union Medical College in China; again, the London School of Hygiene and Tropical Medicine was built and equipped by a gift of half a million sterling. The recent larger gifts of the Foundation in England have been mainly for other than medical purposes, such as funds for the University of London site in Bloomsbury, the grant to the London School of Economics, the grant to Cambridge to include the new library, and about three fifths of the sum needed for the Bodleian extension at Oxford, the foundation stone of which will be laid on June 25 by Queen Mary. The total of these benefactions amounts to £1,872,000.

In 1929, the trustees of the Foundation, again acting with the free hand which the policy of Rockefeller accorded them, absorbed a fourth trust set up some years earlier by the founder, the Laura Spelman Rockefeller Memorial, named after his wife and dedicated to the aid of the social sciences and to the welfare of children. The work of the whole now comprehends not only the international health division of the Foundation and the social sciences division of the Memorial, but also divisions for medical sciences, natural sciences and the humanities.

A characteristic of the Rockefeller philanthropies is that their practice comes from time to time under systematic review and revision by the trustees. This is done in order to meet the altering social needs of given countries. Vigilant attention to system, at home in the General Education Board and in the Institute for Medical Research, abroad in the Foundation whose work now encompasses the world, is the heritage of the business genius of John D. Rockefeller.

Regularities and Irregularities in the Ionosphere

PROF. E. V. APPLETON, in the Bakerian Lecture before the Royal Society, delivered on June 10, surveyed the information derived from radio sounding of the ionized regions of the upper atmosphere and compared the results with those derived from a theory of simple layer formation by solar ionizing radiation, travelling rectilinearly and attenuated according to a mass-absorption law. Such a formation is called a 'simple region'. The comparisons are concerned chiefly with the variation of maximum electron content N_m with solar radiation angle of incidence χ, with the total conductivity for direct currents such as determines the quiet-day magnetic variations and with the high-frequency absorption of radio waves traversing such a region, the two latter quantities being, to some extent, related.

For the lower Region E, where the daytime recombination is sufficiently rapid to maintain the electron concentration close to the equilibrium value, recombination substantially balancing ionization, the value of N_m is found to vary, experimentally and theoretically, as $(\cos \chi)^{1/2}$. The high-frequency absorption for radio transmission, on the other hand, varies theoretically as $(\cos \chi)^{3/2}$. Here fair agreement is found with the experimental seasonal noon variation when the sun is high, as in summer, but the winter values show disagreement, the absorption being then greater than simple theory predicts. For the case of the diurnal variation of absorption during a summer day, Best and Ratcliffe, working at Cambridge, have found good agreement with the theoretical relation.

No evidence is found suggesting the existence of permanent highly reflecting regions in the lower or middle atmosphere.

From the high-frequency absorption and other data, the transverse direct-current electron conductivity of a simple region is estimated and found to be less than that calculated by Schuster and Chapman from the magnitude of the magnetic variations, even after allowing for the revised estimates of upper-atmospheric motions recently made by Pekeris. This difficulty is met by the assumption of the existence of quantities of positive and negative ions in the lower part of the ionosphere, undetectable by radio methods, but which contribute to the conductivity for steady electromotive forces. From this assumption follows an explanation of the high effective electron recombination coefficient in the lower region, where the value is high because of the large number of positive ions. There is a marked difference between the day and night values of the effective electron recombination coefficients in Region E.

The identification of the lower regions of the ionosphere with the levels at which flow the currents affecting terrestrial magnetism is supported by evidence from systematic measurements of the value of $N_{\text{max.}}$, for Regions E, F_1 and F_2, which show that the ionization in Regions E and F_1 varies by about 50 per cent over the sunspot cycle, as does the magnetic variation. The variation of Region F_2 ionization, on the other hand, exhibits no parallelism with the magnetic changes, either in respect of seasonal or sunspot cycle trends, indicating that the magnetic currents do not flow at high levels.

The two types of ionospheric abnormalities, the one associated with bright solar eruptions and the other with terrestrial magnetic storms, were compared and discussed.

An estimate of the actual heights reached by radio waves at the level of reflection leads, in turn, to an estimate of the proportional variation of air density with height for the ionized component. From the fact that Region F is found to be some four or five times as thick as Region E, it follows that the local 'scale-height', H, in Region F is correspondingly greater than in Region E. The atmosphere therefore extends to much greater heights than are estimated from the simple exponential decrease of pressure with height found in the lower atmosphere. Such an extension of the ionizable gases to great heights indicates either that the temperature at 300 km. is higher than at lower levels, or else that it is there composed largely of a light gas such as helium. Difficulties in the way of the acceptance of the latter alternative are discussed.

Television Exhibition at the Science Museum

THE choice of the Science Museum, South Kensington, as a venue for the Television Exhibition which was opened there on June 10 is a singularly appropriate one, for not only does it enable an outline of the technical development of television to be well illustrated, but also it will enable the general public to observe and appreciate the value of television as a new form of home entertainment in a manner which is impossible at any commercial demonstration. The Exhibition is to remain open for about three months.

While it is probable that the only way of appreciating fully the entertainment value of the new service is by the installation of a receiver in one's own home, yet an endeavour has been made at the Science Museum to enable the general public to observe the broadcast programmes for considerable periods by the installation of eight receivers, one from each of the principal manufacturers. These receivers will be in operation daily from 3 p.m. until 4 p.m., receiving the B.B.C. programme, and they will also be operated at intervals throughout the day by means of a film transmitter which has been specially installed in the Exhibition by Messrs. A. C. Cossor, Ltd., for this purpose.

In the technical section of the Exhibition there is a considerable number of exhibits to illustrate the past and present trends of development. The early work of J. L. Baird is illustrated by several exhibits, and there is a working demonstration of the 30-line television which was broadcast from 1932 until 1935. An important part of this section of the Exhibition is devoted to the development of cathode ray tubes. The old Crookes and Braun tubes are shown in operation, and all the important stages of development of the modern television tube are illustrated by appropriate exhibits.

From the scientific point of view, there can be little doubt that the chief interest is centred around a series of exhibits which have been provided by the Scophony Company, relating to their system of large-screen television. As is indicated in the handbook which has been produced in connexion with the Exhibition, one of the major difficulties of large-screen television is that of controlling a sufficient intensity of light and of projecting it on to the screen. The familiar Kerr cell is practically useless for large-screen television since the optical difficulties and low efficiency are insuperable, even if the cell could be made to operate at the very high frequencies required.

The Scophony system makes use of a patented 'supersonic light control cell' in which the principle of diffraction is employed to control the light intensity. The cell consists of two pieces of glass, between which is a transparent liquid; the beam of light is passed through this liquid. A small plate of piezoelectric quartz is mounted at the base or side of the cell and connected with a source of high-frequency oscillations. The mechanical oscillations thus induced in the quartz crystal produce stress waves in the liquid, which travel through the liquid in a direction transverse to the beam of light with a velocity equal to that of sound in the liquid. The waves in the liquid cause the production of diffraction spectra, the intensity of which is proportional to the intensity of the quartz oscillations. By stopping out the normal ray through the cell and by modulating the quartz oscillations by the incoming television signals, the light in the spectra may be employed to form the television image on the screen.

Used in this simple manner, the supersonic light control would possess no great advantage over the Kerr cell. Its great superiority lies in the fact that, with scanning and optical systems of appropriate design, the velocity of the transverse waves of the cell enables between 400 and 500 elements of the picture to be simultaneously active. With a cell of the Kerr type, only a single elemental area can be active at any instant.

The optical system employed makes use of crossed cylindrical lenses for focusing the light beam, thus making possible the use of very small rotating scanners. The focusing and scanning systems associated with the supersonic light control are radically different in design from any previously used for mechanical systems of television. Space must forbid a description here, but the special features are all illustrated by suitable exhibits.

The Scophony Company's exhibits conclude with two demonstrations of large-screen television, one of which employs a screen measuring 5 feet by 4 feet. The programmes are being transmitted by radio from the Company's laboratories at Campden Hill on a standard of 240 lines, 25 pictures per second.

Another exhibit relating to large-screen television is one provided by the Baird Company of an experimental 'projection cathode ray receiver'. This exhibit comprises a conventional receiver, but instead of reproducing the picture on the fluorescent screen of a large-diameter cathode ray tube, an extremely bright image is reproduced on the screen of quite a small tube. A few inches in front of this tube is fitted a wide-aperture lens which projects an enlarged image on to a ground glass screen placed two feet in front, thus providing an image measuring 18 inches by 12 inches. This type of receiver is only experimental at present, and it is understood that one of the chief difficulties is the short life of the screen of the high-intensity cathode ray tube.

Although the Exhibition gives some indication of a trend towards larger screens, one is forced to wonder if a genuine demand for larger screens exists. Obviously, the larger the screen, the larger is the overall bulk of the apparatus, and, to some extent, the larger is the initial cost and upkeep. If, as seems likely, the future development of television proceeds on the lines of home entertainment, the size and cost of a receiver are of vital importance, and while a small increase in the size of the screen as provided on the present commercial receivers would be an improvement, there is a wide belief amongst owners of receivers that the present size of screen is adequate for home entertainment purposes.

There is, however, a potential field of application for television in the provision of entertainment for large audiences in public halls and cinemas, especially when the broadcasting of important current events becomes a daily feature of the television programmes. For such applications, receivers having the largest possible screens will be required.

The Fuel Research Station

ANNUAL VISITATION

THE Fuel Research Station at Greenwich, the headquarters of the fuel research organization of the Department of Scientific and Industrial Research, was inspected by nearly four hundred representatives of science and industry on June 1. The visitors were received by Sir Harold Hartley, chairman of the Fuel Research Board, and the director of fuel research, Dr. F. S. Sinnatt.

The work of the fuel research organization is divided into a number of programmes which are given a different degree of priority from year to year; individual programmes may be curtailed, concluded or extended according to national and industrial requirements.

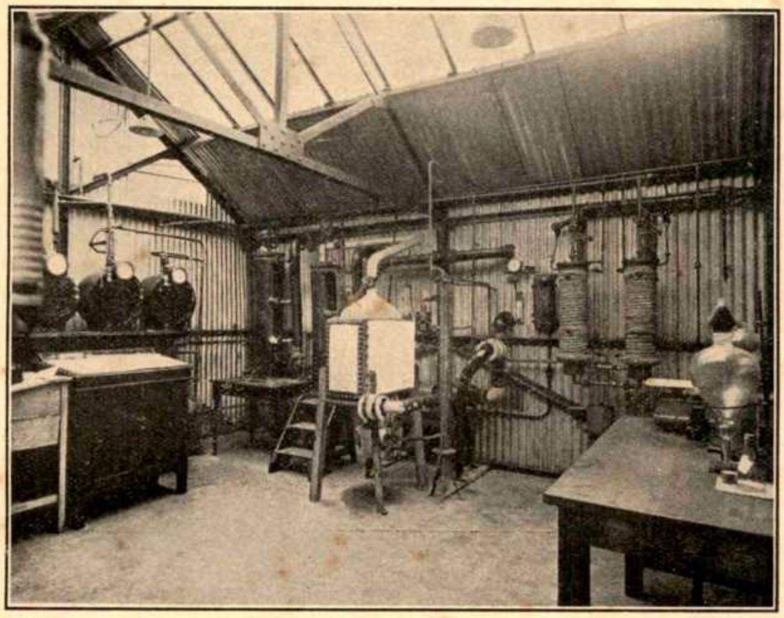

Fig. 1.

EXPERIMENTAL PLANT FOR THE SYNTHESIS OF HYDROCARBONS FROM MIXTURES OF HYDROGEN AND CARBON MONOXIDE. *Crown copyright reserved.*

The National Coal Survey is one of the major programmes. It is necessarily carried out at central points in the chief coalfields, where nine fully equipped laboratories have been established. In these laboratories the properties of the coals of the districts are examined, but equipment is available at the Fuel Research Station for extending the scale of the investigations, so that the results may be applied in industrial practice. Detailed knowledge of the coal seams is becoming increasingly valuable as the methods of utilizing coal grow more precise. New processes such as hydrogenation call for coals with special characteristics, and the study of these is incorporated in the scheme of work at Greenwich.

This scheme comprises laboratory and large-scale investigations of the following problems:

(1) Screening, washing and sizing of coal.

(2) The combustion of coal (*a*) in a marine boiler and (*b*) in the pulverized form, and the elimination of dust and sulphur from the flue gases.

(3) The hydrogenation of coal and tar.

(4) The carbonization of coal.

(5) The complete conversion of coal into gas.

(6) The synthesis of hydrocarbons from mixtures of carbon monoxide and hydrogen.

(7) The burning of coal in the open domestic grate.

(8) The use of pulverized coal in the internal combustion engine.

A brief description of the nature of these problems and of the recent advances made is given below.

(1) Work on the purification and cleaning of coal has lately been concerned with the elimination of dust. Coal treated, according to its type, with 3–20 lb. of oil per ton is quite freed from dust, and possesses certain characteristics which may be of commercial significance. The effect of the presence of very fine material, largely fusain and clay, upon the efficiency of coal washing has also been studied and a process for eliminating this fine material has been developed. Advances have been made in the development of the so-called 'desliming process'.

The importance of the size of coal is being recognized to an increasing extent in industry, and, in collaboration with a number of collieries in several of the coalfields, an exhaustive study is being made of the problems associated with the production of sized materials. This work is being reinforced by more fundamental study at the Station and at the Imperial College of Science, South Kensington.

(2) Since the system, devised at the Station, of burning coal in the pulverized form is already in commercial operation in a number of works, investigation of this problem is now less urgent. Attention has been devoted to the burning of coals containing a low percentage of volatile matter, in order that methods of using this valuable material should be available. The effects upon combustion of blending low-volatile coals with different proportions of high-volatile coal are being explored. The whole problem of the elimination of fine grit and sulphur from flue gases is being investigated, largely with the view to devising a process which can be applied to relatively small units.

(3) The work on the hydrogenation of tar and of coal has aimed at increasing the range of products that can be obtained, and, during the year, methods have been worked out for the conversion of tar and coal into aviation spirit. It has been found possible to produce a volume of aviation spirit equal to the tar treated. Some 140 gallons have been obtained from a ton of coal. The work on the treatment of

high-temperature tar has been partially successful, in that catalysts have now been found by which the tar from vertical retorts can be hydrogenated to produce motor spirit.

(4) The blending of non-caking coals with caking coals is being studied in gas-making plant of the intermittent chamber type.

(5) A process has been worked out by which non-caking coals can be completely gasified in a water-gas plant. If this process can be introduced into commerce, then it will be possible to replace the coke generally used for this purpose and thus conserve the caking coals of the country.

(6) In the search for new products an investigation is in an advanced stage upon the conversion of carbon monoxide and hydrogen into hydrocarbons. This has been worked out in the laboratory, and now a plant is in operation yielding about 10 litres of primary product a day. Lubricating oil has been made from certain fractions of this hydrocarbon product. Fig. 1 shows the actual converter in the centre, and the plant for the removal of organic sulphur from the gases behind it on the left; the condenser is immediately on the right of the converter, and the activated carbon scrubbers on the wall to the right.

(7) Considerable interest is attached to the results which have been obtained upon the burning of coal in the open domestic grate, the investigation of which is financed by funds provided by the Coal Utilisation Council.

(8) As a preliminary study of the combustion of coal in an engine, the effect of coal ash upon engine components is being measured.

University Events

CAMBRIDGE.—Prof. H. R. Dean, master of Trinity Hall and professor of pathology in the University, has been elected vice-chancellor for the academical year 1937–38, beginning in October. He will succeed Mr. G. H. A. Wilson, master of Clare College, whose customary two years of office will then expire. Prof. Dean was educated at Sherborne and New College, Oxford. He went to Cambridge as professor of pathology in 1922, and since then has been a fellow of Trinity Hall, being elected Master in 1929.

Candidates for the Michael Foster studentship in physiology are requested to send their applications, with a statement of the course of research they propose to undertake, to Sir Joseph Barcroft, Physiological Laboratory, by July 7. The student receives the annual value of the fund (about £100), and may be re-elected for a second year.

LONDON.—In recognition of the pre-eminent services rendered, first, by Sir William Beveridge in connexion with the purchase of the Bloomsbury Site and, later, by Lord Macmillan in the raising of the funds necessary to carry out the first part of the building scheme, it has been decided to name two of the halls now completed in the new buildings the "Macmillan Hall" and the "William Beveridge Hall".

OXFORD.—E. S. Duthie has been appointed University demonstrator in pathology for four years from October 1.

Prof. P. Jacobsthal, formerly of the University of Marburg, has been appointed University reader in Celtic archæology for three years from October 1.

Science News a Century Ago

Snow Harris at the United Service Museum

ACCORDING to the *Nautical Magazine* of 1837, on June 12 and 19 lectures were given by Snow Harris at the United Service Museum on atmospheric electricity and the means of defending buildings and ships from its effects. In his second lecture, Harris "described thunder-clouds as insulated and highly charged surfaces, extending sometimes over an area of 40,000 or 50,000 acres, opposed to the surface of the earth as a conductor, with the air as an intervening insulating medium. The electricity accumulated in the clouds, in order to regain a more equal distribution, passes over the lines where the resistance is weakest, or breaks through the intervening air, discharging itself upon the nearest conductor. The lecturer's plan for conducting lightning from ships was illustrated by the model of a frigate floating in a trough of water, with gunpowder at the royal masthead, and with a boat astern filled with gunpowder. A metallic ball, charged with lightning, was made to traverse a wire, by which the gunpowder exploded and also that in the boat, but the lightning was conducted into the water without damage to the vessel. A mast without the conductor, in a similar experiment, was shivered to pieces."

On Lightning Conductors for Ships

FIVE days after Snow Harris gave his lecture at the United Service Museum, Martyn Roberts on June 24, 1837, read a paper to the Electrical Society of London entitled "On Lightning Conductors, particularly as applied to Vessels". Roberts had been led to inquire into the causes of the many accidents to ships through lightning and to suggest improvements. "The conductor most in use", he said, "is a chain, each link of which becomes by the action of the saline moisture in the atmosphere highly oxidated . . . and therefore when the vessel is struck by lightning, every joint in this conductor becomes a point at which an explosion may take place."

Roberts's suggestion was that a metallic rope of fine annealed copper wires should be led from a copper point at the masthead, down the mast and then to a back stay, from which it was to be taken outside the ship and there fastened to the copper sheathing. Harris's conductor consisted of a double copper tape led down the mast and connected to copper bolts passing through the ship's bottom timbers. This plan was favourably reported on in 1839 and was soon widely adopted.

Lyell's Forecast of Submarine Telegraphy

WRITING on June 21, 1837, from Copenhagen to his sister Caroline, Lyell referred to Wheatstone's telegraph. "By-the-bye," he wrote, "have you heard of this wonderful invention? It has made a large figure in my waking dreams ever since I first heard of it at Babbages' and I shall be disappointed if it fail to work a mighty change in the 'march of intellect', at least of civilisation." After describing how Wheatstone had experimented with four miles of silk-covered wire in the crypts of King's College, London, and how with four wires and four needles sixty distinct signs could be sent, he went on, "It has been found that by employing small ropes steeped in india-rubber gum, you may isolate the wires much cheaper than by silk and then each wire shall only cost between £3 and £5 per mile, or for the four wires under £20. Now they had been obliged on the Birmingham and Liverpool railroad to use a very much more expensive telegraph, to give notice of trains coming to tunnels or places where they cross, by means of long iron tubes through which a blast of air is sent which blows a whistle at the end. So when this new rope with the four copper wires is substituted, we shall have not only railway news but all others sent out with the speed of lightning, ciphers being used for private confab. A few days after I left, a tarred rope was to be continued from the end of the four miles of wire, and thrown into the Thames and then carried to the shot tower on the other side, and the rapidity of conveying intelligence through about five miles was to be tried. So perhaps a rope in the sea may carry news from Dublin to Holyhead. . . ."

Captain Graah's Expedition to Greenland

IN the *Athenæum* of June 24, 1837, is a review of the "Narrative of an Expedition to the East Coast of Greenland by Captain W. A. Graah, of the Danish Royal Navy". Captain Graah had proceeded to Greenland at the command of the King of Denmark. He arrived off the coast in May 1828, spent ten months examining the coast towards Cape Farewell and in 1829–30 proceeded to explore the eastern side of Greenland in boats. "The expedition of Captain Graah", said the *Athenæum*, "appears to set at rest for ever the question which it was designed to elucidate. That able officer explored the east coast of Greenland as far north as the latitude of Iceland; he sojourned on it a year and a half; and yet he discovered no vestiges whatever of ancient Icelandic civilization. He found there no iron, no bell metal, no stones with inscriptions or other relics, such as are found on the western coast; and he was assured by the natives, who are well acquainted with the interior of their firths, that they never saw nor heard of ruins in their country."

Autopsy on William IV

THE *London Medical Gazette* of June 24, 1837, contains the following account of the post-mortem examination on William IV, who died on June 20, aged seventy-one years. "On opening the body the heart was perceived to be enlarged and flabby, with a few shreds of soft lymph gluing the surfaces of the pericardium together. The right side was comparatively healthy, but the left side showed very extensive disease of both sets of valves; those of the aorta were ossified, presenting an obstruction to the passage of blood into that vessel, which was rough on its internal surface, but without dilatation. The mitral valves were also ossified, and suffered the blood to regurgitate. The tendency to bony degeneration extended to the respiratory organs, the larynx, trachea, and even the bronchi, being ossified. The left lung was greatly gorged, and the pleuræ on this side firmly united by thick adhesions of ancient date. In the right cavity of the chest were some 12 or 14 ounces of serous fluid, probably poured out during the few days immediately preceding dissolution. The liver was enlarged and granulated; there was also slight granular disease of one kidney. To the medical reader it will be obvious that the deficiency in the general circulation and the overloaded state of the lungs are clearly explained by the dilatation without hypertrophy of the left ventricle, the obstruction of the aortic and patulous condition of the mitral valves."

Societies and Academies

Dublin

Royal Dublin Society, April 20.

D. A. WEBB: Spectrographic analysis of marine invertebrates, with special reference to the chemical composition of their environment. Quantitative data for the occurrence of 25 elements in a variety of forms are presented, and considered in relation to the concentration in which the same elements are found in sea water. Li, B, Sr, Al and Ag can frequently be detected in organisms, but not in concentrations significantly higher than in the environment. Si, Cu, Fe, Co, Ni, V, Cr, Zn, Cd, Sn and F, can be accumulated by some species from food or water in which they are scanty or undetectable. Pb, Ba and Mn, are intermediate. Previous work on the subject is discussed, with more than a hundred references.

J. CARROLL: Potato eelworm investigations. Recent research on the potato root eelworm, *H. schachtii*, has demonstrated conclusively that the eelworm can by itself give rise to 'potato sickness' in its most severe form. It has also been established that healthy crops of potatoes can be produced on eelworm-infected soil whenever the plants make a fair amount of growth before normal hatching of eelworm eggs in the soil commences. Experiments are designed to test the usefulness of trap-cropping with potatoes for the purpose of reducing the eelworm population of the soil.

C. S. RONAYNE: A curious lightning photograph. An exposure of about two minutes with an aperture *f*/6·3 at about 11.30 p.m. B.S.T. in the month of July recorded two flashes. One was completely solarized, and appeared on the print as a thin black line, with the exception of the lower end which was white. Another neighbouring flash was not reversed and appeared white and of appreciable width. This flash showed a thin black edge and black branches. It would seem that the effect must be due to double reversal of the photographic image.

Paris

Academy of Sciences, May 3 (*C.R.*, 204, 1285–1374).

RICHARD FOSSE and ROGER DE LARAMBERGUE: The synthesis of cyanamide by the oxidation of glucose and ammonia. Cyanamide is produced by the oxidation of glucose in ammonia solution by potassium permanganate.

CHARLES ACHARD, AUGUSTIN BOUTARIC and MME. MADELEINE ROY: The optical activity of sera and their proteins separated by the acetone method in the cold. The rotations produced by sera or by the proteins separated from the sera are practically identical. From this it is concluded that the extraction by the acetone method causes no change in the proteins.

GEORGES CLAUDE: The search for aeroplanes lost at sea. Suggests the use of dyes in special containers giving a coloured area visible for about six hours.

SERGE BERNSTEIN: Quadrature formulæ with non-negative coefficients and equidistant abscissae.

JEAN BAPTISTE SENDERENS: Researches on benzoyl chloride. Aromatic ketones.

LAUGE KOCH: The question of the Caledonian chain in northern Greenland.

Paul Vincensini : A property of convex bodies of space of *n* dimensions.

Szolem Mandelbrojt : The regularization of functions.

Radu Badesco : The cyanide method in the extraction of gold. A mathematical discussion of some problems arising in the cyanide extraction of gold ores.

Raymond Tremblot : The spectroscopic triple star 113 Hercules.

Léon Agostini : The flow of air with velocities higher than sound through holes of very small diameter. Experiments were made with holes 0·03–0·5 mm. diameter, and over this range the empirical relation of Emden was found to be verified.

Louis Sackmann : The study of the flow of air in the immediate neighbourhood of a wall. Application to the study of the characteristics of aeroplane wings.

André Labarthe and Alexandre Ponomareff : The internal injection of petrol in an internal combustion motor.

D. G. Dervichian and Maurice Joly : The viscosity of monomolecular surface layers.

Pierre Jacquet : The value of the microscopic method for the study of electrolytic deposits. It is claimed that by using the method described the whole surface of the cathode can be explored, and this cannot be realized by the electron diffraction method.

Alexandre Dufour and Fernand Prunier : The observation of Sagnac's phenomenon with a source of light not forming part of the rotating system.

Boris Vodar : The absorption spectrum of nitrous oxide in the liquid state.

H. Ollivier : Contrast between the laws of thermal variation of the magnetic rotatory power in the case of the nitrates of manganese and gadolinium on one hand and the nitrates of cerium, neodymium, praseodymium on the other.

Mlle. Catherine Chamié : Rapid identification by the γ-radiation of actinium, radiothorium and mesothorium.

Jean Perreu : The heats of saturation and of hydration of sodium sulphate.

Jean Cournot and Mlle. Louise Halm : The methods of testing by corrosion of magnesium and non-protected ultra-light alloys. A description of two methods, one based on loss of weight, the other on gas evolved, which have been proved to give satisfactory comparative results.

Mlle. Jeanne Foret : The action of soda in solution on hydrated tetracalcium aluminate.

Edouard Rencker and Pierre Vallet : The thermal decomposition of ammoniacal copper sulphates. The compound $CuSO_4$, $5NH_3$ when decomposed by heat gives as intermediate products $CuSO_4,2NH_3$, $CuSO_4.NH_3$, and finally the anhydrous $CuSO_4$. The hydrated compound $CuSO_4.4NH_3.H_2O$ gives the same intermediate products.

Emile Carrière and Henri Guiter : The precipitation and determination of vanadates. Study of the completeness of precipitation in solutions of varying *p*H by precipitation with barium chloride, silver nitrate and lead acetate.

Christian Aall : The influence of magnesia on the working of a carbide furnace. Experiments explaining the anomalies and inconveniences resulting from the introduction of magnesia into a carbide furnace.

Mlle. France Bloch : Contribution to the study of the thioacids. The preparation and properties of the acid $C_6H_5CS.SH$.

René Heilmann : Isoamylidene-acetone.

Roger Pajeau : Beryllium bromide in some synthetical reactions. Beryllium bromide does not always give the Friedel and Crafts reaction, but can be used in certain cases.

R. Truhaut : The action of mercuric oxide in alkaline solution on glycocol.

Pierre Bedos and Adrien Rüyer : The stable dibromide of 1,3.cyclohexadiene.

Pierre Chatelain : Is the double refraction of liquid crystals independent of the action of the walls or of the action of the magnetic field ?

André Demay : The connexion between the Dinantian granite, microgranite and rhyolite in the eastern part of the Guéret massif.

M. and Mme. Fernand Moreau : The toxicity and antagonism of certain anions in cultures of *Saprolegnia*.

Maurice Marie Janot : The phenomena of growth produced in plants following injections of hetero-auxin (β-indolacetic acid).

Albert Berthelot and Mlle. Germaine Amoureux : Remarks on the utilization of aseptic seedlings for the study of the formation of tumours.

Fernand Willaume and Osias Binder : The absorption spectra by reflection in the ultra-violet of some basic copper salts and other fungicidal and insecticidal products.

Jean Louis Perrot : The activity of the spermatozoids at the level of the hermaphrodite canal of *Helix pomatia*.

Maurice Fontaine : The amount of flavine in various organs of the eel.

Jehan Vellard : Geographical variations of the poison of *Bothrops atrox*.

Henri Simonnet : Contribution to the study of the fate of morphine in the animal organism.

Léopold Nègre, Albert Berthelot and Jean Bretey : The action of the ethyl esters of certain saturated fatty acids on the evolution of experimental tuberculosis in the guinea pig.

Moscow

Academy of Sciences (*C.R.*, 14, No. 4 ; 1937).

A. Alexandrov : New inequalities for volumes of convex bodies.

B. Gnedenko : Unity of a system of orthogonal functions invariant with regard to the derivation.

M. Kourensky : A method of integration of equations with partial functions of the first order, linear with reference to the Jacobians, and with several unknown functions.

V. S. Ignatovskij : The Laplacean transformation (4).

N. S. Košljakov : Developments into Fourier-Bessel series.

S. Mikeladze : (1) The numerical solution of the differential equation :

$$\frac{d^2u}{dx^2} + \frac{d^2u}{dy^2} + \frac{d^2u}{dz^2} = \Phi(x, y, z).$$

(2) The numerical integration of the Laplacean and Poisson's equations.

N. J. Seljakov : Nature of ordinary ice. The existence of two modifications of ice belonging to different classes of symmetry is proved.

M. Konstantinova-Schlesinger: Percentage of atmospheric ozone at the altitude of 9,620 m. determined by fluorometric procedure.

W. A. Plotnikov: Isotopes.

E. E. Babkin: Vapour tension of a mixture of phosphoric and nitric acids.

M. A. Kločko: Conductivity of electrolytic systems.

I. Lobanov and A. Jungerman: The age of old rocks at Isahkovski Hill.

T. T. Demidenko and E. F. Timofeieva: (1) *Azotobacter* as a source of nitrogenous foodstuff for the higher plants. (2) The role of straw as a source of carbohydrates for nodule bacteria.

D Kostoff: (1) Interspecific hybrids in *Secale* (Rye). (2) Studies on polyploid plants (17). *Nicotiana multivalvis* ($2n = 48$) × *Nicotiana suaveolens* ($2n = 32$) amphidiploid ($2n = 80$).

M. Kliučnikova: Physiological characteristics of vernalized and non-vernalized *Perilla*.

N. I. Efimova: Influence of different substances, artificially introduced into leaves of tobacco, on the development of the disease called 'riaboukha'.

A. A. Kuzmenko: Experiments on the illumination of grains by light of different wave-length.

T. T. Demidenko and E. F. Timofeieva: Influence of nodule bacteria and *Azotobacter* on the yield of leguminous and cereal plants sown together.

M. I. Saltykovskij: Causes of intermediate cold resistance in wheat hybrids of the first generation.

Forthcoming Events

Tuesday, June 22

Institution of Heating and Ventilating Engineers, at 7.—A. F. Dufton: "The Air we Breathe".

Thursday, June 24

London School of Economics and Political Science, at 5.30. Oration Day.

Sir William Beveridge: "The Place of the Social Sciences in Human Knowledge".

Saturday, June 26

Royal Meteorological Society.—Summer meeting to be held at the Solar Physics Observatory, Cambridge.

Association of Technical Institutions, June 25–26.—Annual Summer Meeting to be held at Blackpool.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Lecturer in Mechanical Engineering in the Hull Municipal Technical College—The Director of Education, Education Offices, Guildhall, Hull (June 21).

Head of the Department of Hygiene and Public Health in the Battersea Polytechnic, S.W 11—The Principal (June 26).

Lecturer in Geography in the Portsmouth Municipal Technical College—The Registrar (June 26).

Lecturer in Chemistry in the Battersea Polytechnic, London, S.W.11—The Principal (June 26)

Lecturer in Physics and Methods of Teaching Science in the Borough Road College, Isleworth, Middlesex—The Principal (June 26).

Assistant Masters to teach Engineering and Science and Mathematics in the Bolton Municipal Technical College—The Director of Education, Education Offices, Nelson Square, Bolton (June 30).

Lecturer in Production Engineering and Lecturer in Electrical Engineering in the Central Technical College, Birmingham—The Principal (June 30).

Assistant for Computational Work, etc., in the Mathematics Department, Imperial College of Science and Technology, South Kensington, S.W.7—The Secretary (June 30).

Senior Physicist, Chemist and Research Assistant in Biochemistry on the staff of the Wool Industries Research Association—The Secretary, Torridon, Headingley, Leeds, 6 (June 30).

Lecturer in Biology and School Gardening in the Swanley Horticultural College for Women, Swanley, Kent—The Principal (July 1).

Biochemist in the Rowett Research Institute, Aberdeen—The Secretary (July 1).

Demonstrator in the Physics Department, Guy's Hospital Medical School, London Bridge, S.E.1—The Dean (July 2).

Psychologist (woman. part-time) in the Maudsley Hospital, Denmark Hill, S E 5—The Medical Superintendent (July 3).

No. 3530 SATURDAY, JUNE 26, 1937 Vol. 139

Native Policy in the Empire

LORD NOEL-BUXTON, in bringing forward a motion in the House of Lords on June 9 that native policy in the Empire should be considered in the present session of the Imperial Conference, raised a question of wide and far-reaching implication, involving the status and well-being of vast populations of backward peoples who, whatever their present grade of civilization and condition of tutelage, are nevertheless members of the Empire, and, presumably, will hand on that privilege with its rights and duties to their descendants.

The wording of the motion was as follows:

> That this House, in view of the divergences in native policy now developing in different parts of his Majesty's Dominions and Dependencies, believes that the time has arrived for the Imperial Conference to formulate such policy in broad outline, with a view to protecting the rights and promoting the advancement of all races of the Empire, whatever may be their religion and colour, and that such policy should be based upon the principle of trusteeship.

It was, by leave, withdrawn; but its exact and comprehensive phraseology will not be forgotten when, as is inevitable, the question is raised again and further discussed.

The motion forced not one, but several cards. In the debate which followed, discussion tended decidedly to criticize, defend or extenuate existing policies in native administration, rather than to discuss the merits of the substantive proposal. This is not entirely to be regretted. It afforded an opportunity for expression of opinion on the principle of 'trusteeship', upon which the motion had asked for a direction from their Lordships. An important exchange of views emerged, which might have been stifled at its inception by an official intimation that at this late date it was impossible to entertain the proposal.

In supporting his motion, Lord Noel-Buxton had little difficulty in making out a case. It is probable that most will agree that the Imperial Conference affords the best, perhaps the only, effective machinery for the full and free discussion of the position, which is not only fast becoming anomalous, but also may—indeed in Africa inevitably will—become dangerous, unless handled with foresight and statesmanship. It is not without significance that Mr. Ormsby-Gore, in his review of the affairs of the Colonial Office during recent years before the Imperial Conference on May 31, stated that he considered that the main political problem which confronts the Colonial Office is still "the relationship between natives and non-natives, both European and Asiatic, in many territories, following the growth of education and the awakening of political consciousness". It cannot be doubted that a colonial administrator of his experience must also have had at the back of his mind the problem as it is manifested in instances which were not under review. In a matter of so delicate a character as this question has become under the provisions of the Statute of Westminster, the initiative demands a strong force of informed opinion as a stimulus to any action which will ensure discussion on an Empire-wide basis.

The anomalies which were adduced by Lord Noel-Buxton in support of his argument might be multiplied manifold; but it was sufficient for him to contrast the position in West Africa and in New Guinea with the conditions of the pass system and under-colour bar legislation to demonstrate the gulf that lies between what are, broadly speaking, two schools of thought in approach to the problem of the backward races of the Empire. On one side, as in West Africa, the native is afforded full opportunity for educational and economic development, as well as a measure of co-operation in the administration of affairs. In New Guinea, among peoples who a brief time past were head-hunters, living in the stone age, education in the purpose of administrative measures and some participation in their working have been productive of even an enthusiasm for paying taxes. On the other hand, in South Africa, where racial feelings run high, the prevailing policy is one of repression and domination.

On the main principle, so far as it affects the natives of territories directly under the control of the British Parliament, their Lordships' expression of opinion is virtually unanimously on the side of the benefit of the native being the paramount interest of administration. A word of caution was put forward by the Marquess of Lothian, who in sympathy with the patent difficulties of the Colonial Office, stressed the obligation to white settler as well as native; but the feeling of the House was such as to justify the view that the aim of the Government as stated by the Marquess of Dufferin, Under Secretary of the Colonial Office, "to govern the indigenous races in their own interests and with a view to their elevation in the scale of civilization", will not be allowed, in this 'place' at least, an interpretation which would permit, for example, the natives of the South African Protectorates to be exposed to such regulation as it has been proposed to apply to the indigenous inhabitants of the mandated territory of South-West Africa.

It is possible that some may feel with Lord Bledisloe that at the present moment the needs of the situation will best be met by "the Government on the spot" rather than by any attempt to secure uniformity in a policy formulated by the Imperial Conference. Such a policy would have to apply to different races in different parts of the world, and this, it was maintained by Lord Dufferin in his reply on behalf of the Government, precluded the possibility of dealing with the varied conditions as a unitary whole. There is indeed much to be said for this point of view. Obviously the problem differs from one territory to another. In Canada and Australia, for example, it varies in essential features from the problem of West Africa—the difference in the relative proportion of native and white alone places the latter in another category; but notwithstanding innumerable and important variations in detail, which necessitate elasticity in organization and machinery as between one part of the Empire and another, the inspiring principle may and should be the same, if trusteeship be adopted as the valid basis of relationship between ourselves and the less advanced races.

The eye of the practical administrator must necessarily be directed in affairs to the next step; but even so, it is well to be sure of the general direction in which that step should lead. The state of affairs which has arisen in regard to the indigenous population of Nyasaland is largely the outcome of well-intentioned but misdirected effort in the past. The measures which are being taken to cope with the situation there, as reported by Mr. Ormsby-Gore in his annual survey of colonial affairs in the House of Commons on June 2, indicate the desirability of a unity of outlook in dealing with certain aspects of the native question in East and South Africa as a whole.

The aim of the Union of South Africa is to ensure the stability of a great and prosperous white man's country; but the native population outnumbers the white by something like four to one. Now, when Black Africa as a whole is awakening to an intense desire for development in one direction or another, South Africa is sitting on the safety valve. Over against the Union's policy of segregation stands as an alternative 'trusteeship'. But trusteeship is no more than a means to an end. Unless its function is interpreted constructively and in the light of scientific study of native institutions and the effect on them of the cultural impacts which must follow from the assumption of the obligation which trusteeship entails, premature inculcation of European ideals, social, ethical and economic, may prove no more beneficial and no less dangerous in the long run than segregation. It cannot be repeated too often, nor too insistently emphasized, that the time has now come when the ultimate aim of such measures as 'indirect rule' and 'trusteeship' should be defined in precise terms. In the formulation of this aim the prior necessity of anthropological study should not be ignored. The anthropologist alone is competent to determine and bring together the data upon which it will be possible to define the direction and rate of change least likely to bring disintegration and disaster in its train.

Hydrography of the Atlantic Oceans

Schichtung und Zirkulation des Atlantischen Ozeans

Lieferung 3: Die Troposphäre. Von Albert Defant. (Wissenschaftliche Ergebnisse der Deutschen Atlantischen Expedition auf dem Forschungs- und Vermessungsschiff *Meteor* 1925–1927, herausgegeben im Auftrage der Notgemeinschaft der Deutschen Wissenschaft von A. Defant, Band 6, Teil 1.) Pp. iii+289–411. (Berlin und Leipzig: Walter de Gruyter und Co., 1936.)

THE oceanic troposphere, like the corresponding section of the atmosphere, is a relatively shallow layer marked by steep temperature gradients which contrast strongly with the more even conditions of the stratosphere. Prof. Defant and his colleagues have employed these terms consistently since 1929. The waters of the arctic and antarctic regions belong entirely to the stratosphere, and in the Atlantic Ocean the troposphere extends from 45° S. to 55° N., to a depth of 600 metres and 950 metres in the southern and northern subtropical regions, and to 300 metres near the equator.

Prof Defant's account is based largely on the observations made at 242 stations by the *Meteor*, but with the thoroughness which characterizes all the work published from the Institut für Meereskunde, no source of information has been overlooked, and, in all, the data obtained by twenty-three expeditions have been used.

The main tropospherical currents are horizontal and are confined to the upper strata, but there is also a vertical circulation with widespread influence on the structure of the layer. In the southern and northern subtropical regions, where anticyclonic current systems lead to accumulations of highly saline surface water, there are sinking movements; and in the equatorial zone, which is mainly a divergence region, there are ascending currents.

Owing to two counteracting influences, the powerful warming of the surface water by radiation from sun and atmosphere, and the cooling of the sub-surface water by horizontal advection, the troposphere becomes resolved into three strata: an almost uniform surface stratum, a discontinuity stratum in which temperature and density change rapidly with depth, and a more extensive underlayer which has been called the sub-troposphere.

The surface stratum belongs mainly to the region of the trade wind drifts (the north and south equatorial currents), but it can be distinguished, though not so clearly, as far as 30°–35° S. and 25°–30° N. Its depth is 140 metres in 20° S., 85 m. in 5° N., and 195 m. in 25° N.; but at the equator and in 10° N. the surfaces of equal density sweep upwards until, on either side of the depression in 5° N., the depth of the uniform stratum is only 70 m. and 53 m. The depth also varies from east to west, being greater in the west, and there are minor variations that are best studied from the author's charts.

The upward sweep of the density surfaces at the equator and in 10° N. is worthy of particular notice. As Sverdrup showed for the Pacific Ocean, the convexity in 10° N. exists because this latitude is the thermal equator of the ocean, and the second upwelling, at the equator, because the effect of the earth's rotation is symmetrical about the equator. The south equatorial current extends into the northern hemisphere as far as 5° N., and the influence of the earth's rotation makes its density surfaces slope downwards to the south in the southern hemisphere and downwards to the north in the northern hemisphere.

In the region of the equatorial counter-current, between 5° N and 10° N., the density surfaces slope upwards to the north, and since such a slope is dynamically stable only if the surface current flows eastwards, it follows that the counter-current is not entirely a compensation current as hitherto supposed.

The discontinuity stratum of the troposphere, marked by a sharp decrease of temperature and increase of density with depth, has an average thickness of 50–100 m. It is traversed by far-reaching undercurrents which have their origin in the subtropical accumulations of surface water, and are made conspicuous by their high salinity. One of the most striking is the *southern hemisphere undercurrent*, which leaves the southern subtropical region and flows northwards along the coast of South America to join the large volume of subtropical water carried by the Gulf Stream.

The sub-troposphere is the least characteristic of the three strata. The temperature and salinity decrease with depth but more slowly than in the discontinuity stratum, and the activity of the water circulation diminishes. The lower boundary of the layer is marked by slightly greater changes, but since the water in the boundary region escapes the aerating influence of both tropospherical and stratospherical currents, its most distinguishing feature is a very low oxygen content.

The value of the report under notice is greatly increased by tables, sections and charts; all the plates are magnificently produced in colour, and they are very easy to understand. The report is a very worthy addition to the accounts of the hydrography of the deep and bottom waters already published in the same series.

G. E. R. DEACON.

Cancer and Diet

Cancer and Diet:
with Facts and Observations on Related Subjects. By Dr. Frederick L. Hoffman. Pp. xx+767. (Baltimore, Md.: Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1937.) 5 dollars.

ABOUT one half of this book consists of reviews of work concerned with questions of diet or cancer and the possible relationship of these to each other, so far as can be found in publications in the author's own library. Most references to original work are obtained from abstracts in the *Cancer Review* and *American Journal of Cancer*. Many extracts are given from the *Cancer Review*, which came to an end in 1932, though the extracts show how valuable a review it was.

Of the work published on diet and cancer, "so much is contradictory that no balance can be drawn between the advocates of one theory or another". Certain foods which have in the past been suggested as the cause of cancer are almost certainly innocuous. Thus potatoes have been indicated as a cause of cancer, apparently because potatoes are themselves subject to disease, but Dr. Hoffman points out that the cancer mortality in Ireland, where potatoes are widely consumed, is lower than in the rest of the British Isles. It has been claimed that injection of tomato juice into animals produces cancer, but there is absolutely no evidence that the eating of tomatoes can induce malignant changes in the body. This book shows that no one food can be considered a cause of cancer.

The second half of the book deals with Dr. Hoffman's own contribution to the subject. He has composed a questionnaire which has been answered by 2,234 people suffering from cancer and by 1,149 controls. The questionnaire deals with age, religion, race, physique, food preferences and medical history. The answers to the questions are tabulated in the appendixes according to sex and occurrence of cancer. In most of the answers there is no significant difference between normal and cancer cases. One of the most striking differences, however, is in the religious categories. Of the cancer cases 57 per cent were Protestant and 32 per cent Catholic, while of the normal cases 45 per cent were Protestant and 42 per cent Catholic. Dr. Hoffman does not discuss the significance of these differences, which may be due to an error in sampling. Examination of food preferences suggest that the vitamin and total food consumption of cancer cases is excessive, and Dr. Hoffman's main principle is that a diminished food intake would reduce the incidence of cancer. He admits, however, that this is not yet definitely proved and is himself seeking further evidence along the lines which he has already used.

The idea that the average man consumes more food than is good for him is fairly common, particularly among American biologists. Chittenden recommended a protein intake which was about half that present in a normal Western diet, and Raymond Pearl considered that smoking lengthened life because it reduced appetite.

The closing sentence of this book is: "I consider my own duty discharged in presenting the facts as I have found them, which lead to the conclusion that overnutrition is common in the case of cancer patients to a remarkable and exceptional degree, and that overabundant food consumption unquestionably is the underlying cause of the root condition of cancer in modern life." This conclusion is difficult to reconcile with the fact that cancer is not rare among peoples who are not considered to be overnourished, such as Japanese, Chinese, Malays and Filipinos. Further evidence which is contrary to Dr. Hoffman's thesis is given by figures in the Registrar-General's Decennial Supplement for England and Wales (1921), showing that cancer is more common in the lower social classes, which are usually assumed to live on a less liberal diet than the upper classes.

The possibility of error in the method of examining questionnaires is obviously very great as the personal element is predominant in the answers obtained. It is common to meet very fat people who say that they eat practically nothing. Apart from the erroneous answers that may be obtained, the interpretation is extremely difficult to put on a quantitative basis. Finally, assuming that there is a correlation between the incidence of cancer and high food intake, a large appetite might conceivably be due to some inherited factor linked to another factor predisposing the individual to cancer. The relationship of cancer and diet is of interest and may be of importance, but the true nature of this relationship is difficult to determine

Radio-Frequency Technique

Lehrbuch der Hochfrequenztechnik
Von Dr. Fritz Vilbig. Pp. xx+775. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1937). 32.80 gold marks.

TO attempt an up-to-date survey of radiotechnics, a subject in which the progress daily astonishes us by its variety as well as its rapidity, might daunt anyone. Yet, in this textbook of high-frequency technique, Dr. Vilbig has not only attempted such a task but also has executed it most commendably. Writing with the outlook of a student of what is nowadays often called 'light ,engineering', rather than that of a physicist, he has given an extraordinary lucid account of both the science and art of modern radiocommunication, with just sufficient in the way of backward glances at the older-fashioned methods to satisfy the mildly conservative. In short, he tells us all about the new with just as much about the old as is worth remembering.

The book contains twenty-six chapters, of which the first six are devoted to high-frequency phenomena in open and closed circuits and to the propagation of electric waves either along wires or through space and the ionosphere. Thirteen chapters are devoted to thermionic valves and their multifarious uses. For the English or American reader there is here one disadvantage to be noted, for the somewhat lengthy columns of valve data all refer to German tubes (Telefunken or Loewe). If the volume is ever translated into English, this will have to be changed.

Four more chapters deal with the application of apparatus and methods in the maintenance of communication, while the last two chapters deal respectively with television and with the thermal and physiological actions of radio-frequency currents. In the chapter on television we note perhaps most markedly the influence of the author's nationality, but from it we can scarcely fail to conclude that Germany lags considerably behind Great Britain in the matter of broadcast television.

Special mention should be made of the informative diagrams and illustrations. There are also a hundred pages of reference to books and original papers arranged under the chapter headings and subdivided chronologically. This list is like the subject matter of the book itself, up-to-date to the end of last year.

E. V. A.

The Case for Racial Crossing

Half-Caste
By Cedric Dover. Pp. 324. (London: Martin Secker and Warburg, Ltd., 1937.) 10*s*. 6*d*. net.

THERE is need for a scientific work on the subject of race and racial crossing; but the present book can scarcely lay claim to fulfil that need. It considers mainly the social and historical aspects of racial crossing, with some references of a less critical kind to its biological and anthropological bearings. It contains a chapter on the condition of the Eurasians, of whom the author is one, and another on the life of a Eurasian poet. The chapter on "Miniature Melting Pots" gives short accounts of mixed groups in many parts of the world. Another chapter is concerned with racial crossing and its results in South Africa, Chapter x is devoted to the American "Negro" (Afroamericans), followed by another on the racial mixtures of South America.

One can appreciate the author's point of view without sharing it. He looks forward to universal miscegenation as a cure for the world's ills, and favours policies for the "judicious encouragement of interbreeding and the development of mixed groups". But he admits that there is at present "distressingly little evidence of this spirit". It is worth pointing out that even if intercrossing between, for example, whites and blacks were universally regarded as desirable, Europe would still necessarily remain for millennia essentially white and Africa essentially black. Mr. Dover himself quotes the conclusion of Williams on the Maya-Spanish crosses in Yucatan, that after nearly four centuries they "can still be more or less separated into sub-types corresponding to the ethnic elements concerned in the ancestry".

This fact of genetic segregation in racial crosses, together with the great disparities in culture (in the widest sense) between the more divergent human types is, for many, sufficient reason against creating insoluble problems by advocating the further intermingling of mankind's already sufficiently mixed types. Such advocates usually forget that the diversity of climates alone makes it impossible to build the same kind of civilization everywhere, and that there is already a certain amount of racial adaptation to different environments. Intermixture with a distant race breaks apart and redistributes these adaptational differences, to the detriment of the races concerned. No degree of civilization can do away with the need for such adaptations in the more extreme climates, arctic and equatorial. But every biological rule has its exceptions, and certain racial mixtures, such as Indian-white crosses in the wilder parts of Northern Canada, may be justified in their results.

The author has "made the interesting discovery that peoples similar to the Eurasians may be observed everywhere" (p. 277), but it is obvious that such "similarities" are too superficial to count for much against the disparities which exist among crossed types in different parts of the world. The "brown fringe", which the author hopes to see extended as a "portent of a new humanity" would only increase the number of racial types without contributing materially to the solution of racial problems.

Those who are interested in the more controversial aspects of race crossing will find them sympathetically considered in this book. One of its best features is a rather extensive bibliography.

R. R. G.

Contact Catalysis

The Mechanism of Contact Catalysis
By Dr. R. H. Griffith. Pp. xi+208. (London: Oxford University Press, 1936.) 15*s*. net.

THE importance to-day of catalytic processes in the chemical industry are obvious to everyone who is acquainted with the catalytic production of sulphuric acid, the synthesis of ammonia from its elements, the manufacture of nitric acid by the oxidation of ammonia, and the manufacture of liquid fuel both by the direct and indirect hydrogenation of coal. Each year finds more and more applications of catalysis to industry, but so far the development of catalysts has been mainly empirical in character, entailing a mass of detailed and expensive investigation prior to each new application.

In the introduction to the book under review, the author points out that if the phenomena of catalysis had been explored completely, it should be possible not only to give a logical explanation of every known example, but also to predict the conditions under which new reactions could be carried out. Our present knowledge does not yet permit of this, but there have been in the last few years many important discoveries in relation to the mechanism of heterogeneous catalysis, and Dr. Griffith has referred to and attempted to correlate what he considers to be the more important of the numerous publications relating to the study of surfaces and to other properties of catalysts. The author is himself responsible for a number of original papers in the field of catalysis and is therefore well able to present the subject authoritatively. This he has done in a most adequate manner.

Experimental methods employed in the study of reaction kinetics are briefly described in the first chapter, and throughout the book stress has been laid on methods of experiment as well as on the interpretation of results. The study of adsorption of gases by solids has played an important part in elucidating the nature of catalytic action, and a survey of work in this field is presented in the second chapter. The conception of activated adsorption advanced by H. S. Taylor in 1931 has proved a great stimulus to the progress of surface chemistry. In a later chapter the author predicts that the accumulation of facts about the adsorption of a wider range of gases and vapours on surfaces composed of metals, oxides, sulphides and similar surfaces, will eventually prove extremely useful in the development of new catalysts.

The third and fourth chapters deal with promoters and carriers, and with poisoning and retardation. The examination of the catalyst surfaces and the probable spatial arrangement of the adsorbed molecule in relation to the actual configuration of the solid catalyst next receive treatment. It is interesting to note that, at the end of the chapter devoted to the mechanism of catalysis, the author concludes that all recent experimental work on catalysis is leading back to ideas closely approaching the old intermediate compound theory.

The volume contains numerous tables and figures and is provided with an excellent index.

R. T.

The World of Science

By Dr. F. Sherwood Taylor. Pp. xvi + 1064 + 48 plates. (London: William Heinemann, Ltd., 1936.) 8*s.* 6*d.* net.

To those who are fond of encyclopædic omnibus volumes this book will give pleasure. Its avowed purpose is "to answer in simple terms the questions which the ordinary man and woman ask about living creatures, the world and the mechanical devices daily encountered by all". One must admire the successful conclusion of the immense task that the preparation of this book must have proved to the author and his assistants. Nevertheless, parts of the book seem to indicate that the weariness known to all authors of large volumes must sometimes have unwittingly crept over Dr. Taylor, and one can well imagine him struggling with the gigantic array of knowledge represented by the whole of science.

The style adopted does not, in general, make for easy reading, the sentences being, for the most part, short and jerky. The various divisions of the branches of science are set out in tabular form on p. 12. In such an up-to-date book we are surprised at the omission of biophysics, especially as biochemistry is included. There are a few inconsistencies in the book itself. On p. 295 it is stated: "It was a longish step to show that matter of all kinds was made up of nothing but these electrons and positive charges", but on p. 531 we read that "atoms are composed only of three things, electrons, protons, and neutrons". The statement on p. 421 that "ultrasonic waves are transmitted very much as light" is misleading. True ultrasonics behave to some extent in a similar way to light, but the mode of transmission is fundamentally different.

It is unfortunate that some of the diagrams have been reduced so much as to detract considerably from their value. Chemical substances and reactions are frequently shown diagrammatically as groups of spheres representing atoms, in the manner used to represent crystal structure. The advantage of this over the more usual chemical formulæ is open to question, for it seems liable to lead to misconceptions.

Despite these criticisms, however, this book contains a vast store of knowledge, accurately presented, and will form a useful addition to the "ordinary man's" library, and the index will enhance its value as a reference book.

H. R. LANG.

Battlefield of the Gods:

Aspects of Mexican History, Art and Exploration. By Pál Kelemen. Pp. 212 + 61 plates. (London: George Allen and Unwin, Ltd., 1937.) 10*s.* 6*d.* net.

"BATTLEFIELD OF THE GODS" should not be passed over lightly as a travel book of the usual type. The author, it is true, is neither archæologist nor ethnologist and in his description of such of the archæological sites of Mexico and Yucatan as were visited by him, there is nothing new in the way of fact; but he has the trained eye of an artist, and he has pondered to some effect the place of art as a functional element in culture. Hence he is able to bring out the significance of the art and architecture of the ancient peoples of Central America as an expression of their racial history, developing under the influence of their environment. It must be counted as among the more illuminating features of this book that the author's review of post-Conquest development and his studies of ecclesiastical architecture and the Christian religion, as it was adopted by the native, as well as his incidental glimpses of the native mind as it exists to-day, demonstrate vividly how Maya, Aztec and Spaniard have blended to produce what is most characteristic and distinctive in the modern civilization of Central America. In short, in a series of impressionistic sketches he indicates the trend of that continuity of cultural development from pre-Conquest days, of which the evidence is being collected, more scientifically perhaps, but not more convincingly, by the organized research of the Carnegie Institution of Washington.

It should be added that some remarkable examples of post-Conquest ecclesiastical art are figured and described here, which have not previously been published. This book should do much to convince English readers of the interest of a branch of archæology which, unfortunately, has too few supporters in Great Britain.

The Statesman's Year-Book:

Statistical and Historical Annual of the States of the World for the Year 1937. Edited by Dr. M. Epstein. Seventy-fourth annual publication, revised after Official Returns. Pp. xxxvi + 1502. (London: Macmillan and Co., Ltd., 1937.) 20*s.* net.

FEW volumes cover a more comprehensive field than this annual, which as usual has been revised up to the end of March in the year of issue. Government, area, population, education, finance, production, commerce, communication and many other topics are descriptively and statistically treated for every State in the world. In addition, there is information on currency, weights and measures and even names of diplomatic representatives, and long lists of authoritative books of reference. The British Empire and the United States of America receive the fullest treatment and occupy nearly half the volume, which despite its many pages occupies a remarkably small bulk. An exhaustive index facilitates reference. As usual, two coloured maps are included: this year they show respectively the Sanjak of Alexandretta in relation to Syria, and Abyssinia with surrounding territories. A number of tables give world production of several important commodities and particulars of fleets and merchant shipping.

Builders' Estimates and Pricing Data:

their Preparation and Analysis. By Henry A. Mackmin. (The Directly-Useful Technical Series.) Second edition, revised and enlarged. Pp. xii + 227. (London: Chapman and Hall, Ltd., 1936.) 12*s.* 6*d.* net.

THIS work is the third edition of a book first published in 1926 and incorporates not only new matter on recent developments in building construction, but also the methods of estimating used in the Midlands and the north, as well as in London and the south. It is extremely readable, and can be suggested as well suited to those engaged in the technical side of building generally.

B. H. K.

The Nature of Snow*

By Gerald Seligman

ALL ice and snow forms are crystalline. To demonstrate the crystalline structure of even an apparently non-crystalline body such as a shapeless block of ice, Tyndall passed a beam of light through it. If we repeat this experiment we find that hexagonal cavities are produced and that the process of crystallization is, as it were, reversed, so that we get what are sometimes called 'negative crystals', or as I prefer to call them, 'negative figures', within the body of the ice (Fig. 1). As the action of the beam proceeds, each figure becomes filled with the water which occupied it as ice. In the centre of each figure a bubble forms, which, in reality, is a vacuous sphere due to the water taking up less space than the ice.

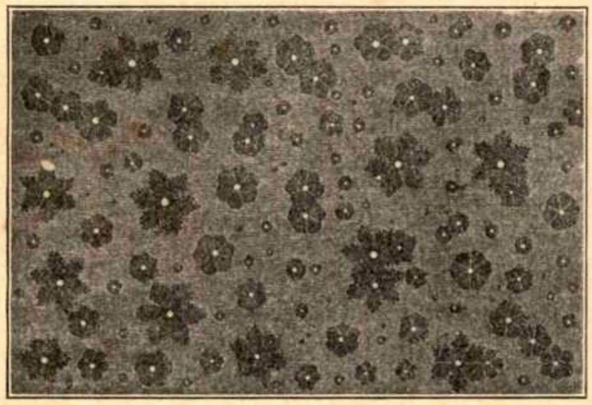

Fig. 1.
NEGATIVE FIGURES IN ICE.
Reproduced from "The Glaciers of the Alps", by J. Tyndall (by courtesy of Sir John Murray).

These 'negative figures' are very useful in telling us the arrangement of the crystals in a mass of them, such as, for example, in glacier ice. They lie at right angles to the principal axes of the ice crystals, and parallel to the original freezing surface. Therefore, in pond ice, as we should expect, the 'negative figures' are found parallel to the surface of the pond, and this confirms that the ice crystals grow with their principal axes perpendicular to the surface. In artificial ice they are often found more irregularly placed, the incidence of the refrigeration having been irregular.

In glacier ice we find that the crystals are orientated without any order, for the reason that the glacier crystals have grown from snow grains, each crystal preserving the haphazard orientation of the original snowflake as it fell on to the surface.

SUBLIMATION

Everyone who wishes to understand snow must understand sublimation. Sublimation is, of course, the transition of a solid into a gas and its immediate reconversion into the solid, without entering the liquid phase. Many substances do this, and ice is one. Under suitable conditions it evaporates direct into water vapour, and, again under suitable conditions, this will reconsolidate, or, in loose parlance, sublime, into ice without any water appearing.

The evaporation of ice into water vapour has probably been seen by every winter visitor to the Alps; on a dry, warm day a patch of snow on a rock will vanish into thin air without leaving a trace of moisture. Among other factors, principally those of wind and the relative humidity of the air, ice evaporation is promoted by a relatively high ice temperature; the reconsolidation of this vapour into ice is brought about by a relatively

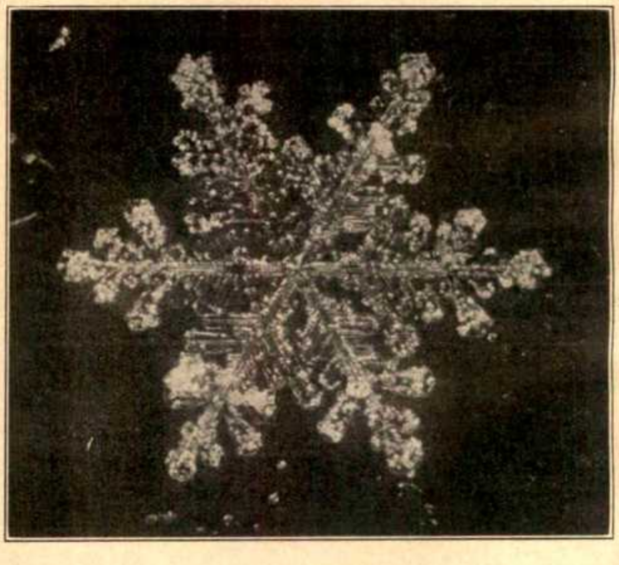

Fig. 2.
A TYPICAL DENDRITIC SNOWFLAKE (× 15).
Photograph by G. Seligman.

---

* From the Friday evening discourse at the Royal Institution delivered on January 22.

low temperature. There is scarcely a single snow phenomenon that does not to some extent depend on sublimation. The genesis of snow itself—the growth of the snowflake—is nothing but the sublimation of water vapour out of a supersaturated atmosphere. In this case sublimation starts upon nuclei floating in the air, which may consist of grains of dust, pollen or chemical salts.

SNOWFLAKES

The designs of snowflakes are probably infinite. Bentley, a distinguished American experimenter, photographed some 5,000 types, and believed that he had only attacked the surface of the possibilities.

The simplest form of snowflake is a hexagonal plate about ten times greater in diameter than in thickness. Its diameter might be as large as 1 mm. or 2 mm., or much smaller. More common in the Alps are the dendritic flakes (Fig. 2). When snow falls at a temperature close to freezing point, we get the large cotton-woolly aggregates which are so common in Great Britain, the word 'flake', in fact, denoting its woolly character.

Another form of flake is the prism, and its variant, the needle. Fascicular bundles of needles frequently cross each other at 90°, departing from the usual 60° symmetry of the ice crystal. This is extremely rare in other forms of ice crystal, except in the case of window hoar—the beautiful crystals which form on the inside of window-panes—and in this case also it is of constant occurrence.

The growth of dendritic flakes was explained by Wegener from work done on the crystallization of iodoform by Lehmann in 1888. Using a slightly supersaturated solution, Lehmann stated that first of all a tiny hexagonal crystal formed, and that immediately surrounding it the solution was only saturated, the supersaturated area remaining a little distance away. Consequently, the corners of the hexagon, being closer to the supersaturated part, would grow out, until liquid could penetrate between the rays so formed and build side growths upon them.

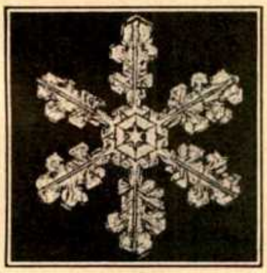

Fig. 3.

Working with iodoform, we have not so far been able to find these two degrees of saturation in the laboratory, but it is a fact that in the sublimed ice crystals which grow on windows, the growing crystal does clear a space all round it. This certainly lends colour to what Wegener has deduced from Lehmann's work. I have observed this space again and again, moving outward as the crystal grows at the expense of the tiny frozen moisture drops covering the pane.

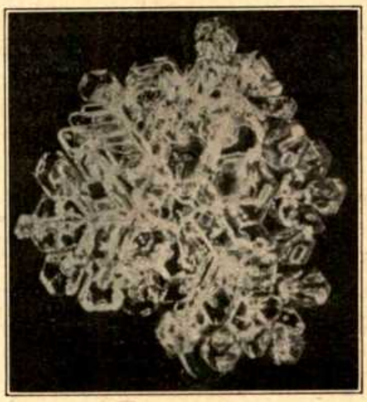

Fig. 4.
A SNOWFLAKE 'ICED-UP' TO FORM A FLAT PLATE OF ICE (× 10).
Photograph by G. Seligman.

Wegener showed, too, that the greater the difference between the vapour pressure of the ice of a flake and that of the surrounding atmosphere —the vapour pressure gradient—the more it favoured the growth of dendritic rays. The lower the vapour pressure gradient, the more the growth of solid plates was encouraged.

With this information it is not very difficult to trace the life-history of a snowflake. Taking the one shown in Fig. 3: at high altitudes, where the vapour pressure gradient was low (owing in this case to temperature and temperature differences being low) the central hexagonal plate was formed. The cold flake then fell to a warmer region, where the vapour pressure gradient increased, and the six rays shot out. Then perhaps it fell out of its snow cloud, when, for another reason (in this case that of lower saturation) the vapour pressure gradient decreased again; a more solid growth resulted and it assumed its final form.

In a converse manner we may be able to obtain a message of the meteorological conditions high up, from the structure of flakes as they reach the earth. This has already been done to some extent, but Nakaya's recent work in making flakes under controlled conditions should enable this, perhaps, valuable addition to meteorological knowledge, to make great strides.

FIRNIFICATION

In any alpine winter snowscape it seems as though Nature has stood still under its winter mantle, and that all is peace. Yet, in truth, the snow cover is a vast and active laboratory in which the flakes are made to undergo incessant and increasing change, until the time when they disappear in spring and commence their long journey to the sea, or, at high altitudes, become converted into glacier ice.

These changes are called 'firnification'. When snow falls, it lies on the ground in the loosest and most impalpable condition. Its specific gravity at this time is about 0·06, that is to say, 1/15 ice, 14/15 air, but under certain conditions of calm and low temperatures, it may be only 0·01, that is 1/92 ice, 91/92 air!

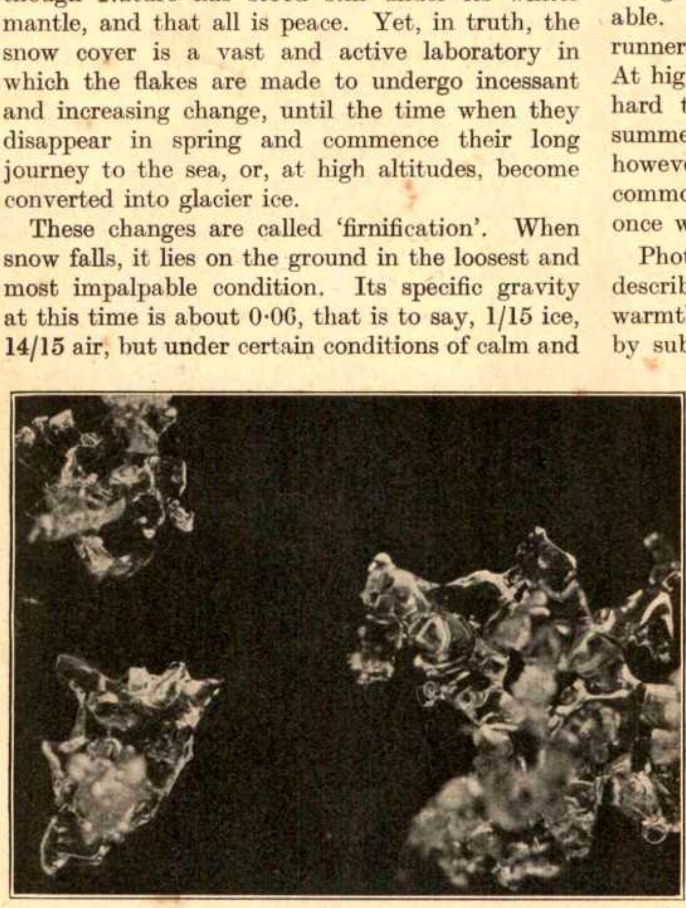

Fig. 5.

ADVANCED FIRN SNOW; SHOWING THE CEMENT BINDING THE GRAINS TOGETHER (× 7).

Photograph by G. Seligman.

The snow immediately begins to settle. The sharp points of the rays evaporate, and the flakes break up, so that the powder of broken flakes sinks together and becomes firmer. Its specific gravity will now have risen to 0·2 or 0·3. At this stage it is called 'powder snow', and is in its most attractive condition for ski-runners, who, as they skim down the mountain-side, can turn in it hither and thither at will.

Then, under the influence of alternate heating and cooling, a crust begins to form on the snow surface which tends first to trip the unskilled skier, and then, as it grows in depth, becomes hard, so that a man climbing the mountain must cut steps in it. In this condition it is known as 'firn snow', from which the whole process derives its name. But when the hot spring sun has thawed the top few inches of hard firn snow at midday, ski are again able to get a grip, and it then forms one of the grandest and fastest ski-ing surfaces imaginable. 'Spring snow' is the name given by ski-runners to this sun-loosened surface of firn snow. At high alpine altitudes the firn snow becomes so hard that, except on south faces and at midsummer, it is almost permanently icy. It is, however, not true ice, which is far rarer than is commonly believed; that stage comes later, the once whitish firn snow becoming blue and glassy.

Photomicrographs provide a key to the changes described above. Commencing with a snowflake: warmth first causes a blunting of the delicate rays by sublimation, some of the water vapour being trapped and resolidified in the centre of the flake, to make a continuous flat plate of ice. The original rays are still visible (Fig. 4). These plates shimmer like diamonds immediately after a snowfall. Seen by moonlight, when the darkness allows the rainbow colours to shine out undimmed, they are a sight never to be forgotten.

At the same time, some of the flakes begin to fracture, and we also see some reconsolidation of the sublimed water vapour in the form of granules. At this stage the snow has settled into the 'powder snow' beloved of ski-runners.

Next we have a light firn stage. The granules are united into aggregates, due to the alternate heating and cooling. This corresponds to the light sun-crust stages. In the earlier stages of firnification, sublimation is probably the chief factor. In the later stages thawing and freezing due to temperature alternations become more common. Regelation probably plays some part, too, throughout the process.

The grains have now grown in size and a cement binding them together is clearly seen. It is this cement which melts first under the influence of heat, turning the hard firn snow into the loose wet grains of 'spring snow'. The thawing of this cement also causes glacier grains to disintegrate when the sun shines strongly on the glacier surface.

There is an interesting similarity here between ice and metals close to their melting points. In the latter the crystal boundaries are also found to be surfaces of weakness. It is believed, but I think not proved, that when ice freezes it rejects any salts from the interior of the crystals and they find their way to the crystal boundaries and into this cement. Certain it is that, as would be expected from an impure ice, this cement has a lower freezing point than the pure ice crystals, and melts first, releasing them to form 'spring snow' or loose collections of glacier grains as the case may be.

It is possible that there is a true analogy between the behaviour of ice and metals in this respect.

Fig. 5 is a photomicrograph of very advanced firn snow and shows the cement. The difference between advanced firn snow and ice is that in the former some air always remains between the crystals. (So long as there is air between the crystals it is, by definition, snow.)

It is surprising that the actual transition of firn snow into glacier ice has never been observed in detail, or recorded more closely than these photographs show in rather incomplete manner. This is to form the subject of a research now in course of preparation.

If we could descend vertically through the firn region of the glacier, as if by a shaft, we should there too find the snow becoming denser and more ice-like; and that is how it is hoped to carry out the research on the transition of snow into ice mentioned above.*

AVALANCHES

The modern study of snow really derives from a need to understand and prevent (or avoid) avalanche accidents. The study of firnification has thrown a powerful light on the most common winter avalanche—that which comes down soon after a fall of fresh snow.

Fig. 6 shows firnification photomicrographs in diagrammatic form: In *A* the very new snow is interlocked by its rays, and is therefore safe on all but very steep hills. In *B* these rays become reduced in size, and the snow particles are therefore mobile. In *C* the flakes break up and form granules, but still lie loose and mobile. In *D* the snow is granular and more compact, and is again safe. *B*, *C* and *D* conditions will occur more quickly if the air is warm. In other words, low temperatures prolong the avalanche danger.

We may summarize the whole lore of this type of avalanche in the following very simple words:

(1) Immediately after a fall slopes are safe, or at least safer than they will become later when the sun shines. (*A* stage.) This has a practical application. If a party of mountaineers is weather-bound in a hut, it should endeavour to make its escape, other things being equal, as soon as a slightest amelioration in the weather has set in, and not wait until the sun has reappeared.

(2) As soon as the air warms up after a snowfall, the snow becomes mobile, first of course on south, and afterwards on north slopes. (*B* and *C* stages.) The practical import of this is that, again other things being equal, escape should be made by north slopes, which are not reached by avalanche danger until later.

(3) Cold conditions prolong the danger.

(4) As soon as the snow has become denser powder or 'settled' it is safe. (*D* stage.)

WIND-PACKING

The effect of wind upon snow is to pack it hard, forming a crust. From such a crust the erosive action of wind-driven grains cuts out fantastic figures, which may form a serious obstacle to the explorer in polar regions, for they may rise in high, so-called sastrugi, covering wide areas. These sastrugi have their steep face to the wind, which has a practical application, especially on a flat plain where the wind may be expected to be constant over wide areas—in a fog they provide the traveller with a constant indication of direction.

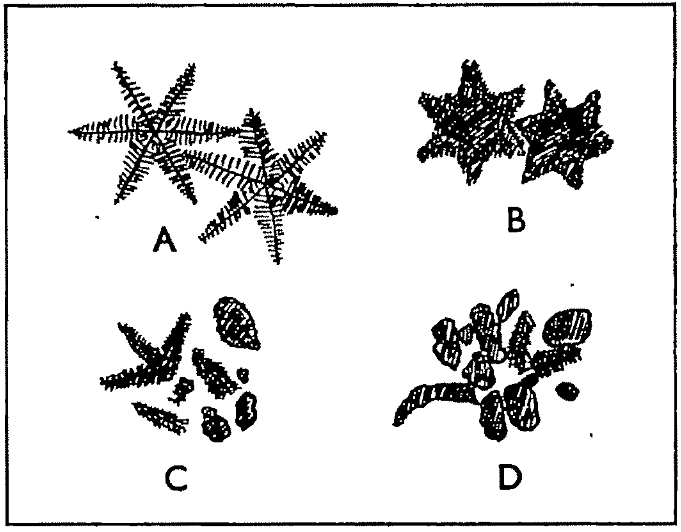

Fig. 6.
DIAGRAM SHOWING THE SAFE AND DANGEROUS STATES OF NEW AND 'SETTLED' SNOW.

Cornices, too, are the result of wind action.

The drifting of snow is a study in itself, and a profound one at that. The deposition of snow in drifts is due to a slackening of the wind speed and consequent deposition of the snow grains it was transporting. If the wind still continues to blow while snowdrifts are forming, that is to say, if the snowdrift is not growing in a complete calm, the hardening, or 'wind-packing' as it is called, will extend right through the drift. If this drifting and packing occur on a steep hillside we get a curious happening. The packed snow, when disturbed by the weight of a man, breaks into blocks which slide down the mountain side, causing what is called a wind-slab avalanche, which may be very destructive.

---

* For this research it is intended to adapt the boring tools of the prospector, and, by the construction of a specially made saw-edged drill head, to bring up undamaged cores of firn snow and ice from different levels in the glacier. Such a tool, constructed for me by Messrs. C. Isler and Co., has already yielded promising preliminary results in glacier ice.

It is characteristic of wind slabs that they do not bind themselves to the hillside, but have a hollow space underneath, which renders them all the more unstable.

Photomicrographs of the snow composing one of these wind-packed drifts or slabs showed considerable uniformity in grain size. This indicated a method of approach towards the proof of what had hitherto only been suspected, namely, that the snow had been drifted, since drifting sorts out the grains into uniform sized groups.

A study was made of a whole series of photomicrographs both of natural wind slabs and of wind slabs made under controlled conditions in an out-of-door laboratory. Ultimately it became possible to make this hitherto unexplained phenomenon, which had sent so many brave and wondering mountaineers to their deaths, yield up several of its secrets. Among other things it became possible to tell the mountaineer where on the hillside he can expect the worst wind-slab avalanches, and under what atmospheric conditions they are to be expected.

To put these findings in a nutshell: they are found on slopes to the leeward of the last snow-bearing wind, when the general condition of the air is damp.

This conclusion has already borne fruit. Ever since the fatal avalanche on Mount Everest in 1922, when seven porters met their deaths, leaders of the expeditions have been puzzled by unaccountable avalanches bursting from the North Col with apparently no prime cause. They have now come to realize that these fall under just those conditions which I have pointed out, namely, a wet wind depositing the snow in drifts on lee slopes, and they have been able to link them up with the advent of the monsoon. As soon as the damp monsoon wind blows over the North Col the glacier on its lee side becomes a death-trap. An alternative route has now been reconnoitred and will, no doubt, be used in future, as soon as the conditions begin to favour wind slab development.

Origin of the Papuan Insect Fauna

By L. Evelyn Cheesman

THE island of New Guinea is a centre of distribution for species belonging to the Papuan fauna, which is very distinct and very rich in variety of forms. Yet the bulk of this huge island is part of the Himalayan geanticline, and therefore geologically recent. Since the fauna cannot have evolved upon land recently raised from the sea, there must have been older land from which the new land was populated.

Palæogeologists such as Ortmann, Lapparent, Arldt and others have postulated a land-mass which during the Middle Cretaceous extended from the Asiatic continent south to New Caledonia and eastward to Sumatra and Java. Some time during the Upper Cretaceous, according to the same authorities, New Guinea became separated from Borneo, Celebes and the Philippines, and also from New Caledonia. Later, the entire island is supposed to have been submerged until the Miocene-Pliocene folding movement raised the central ranges and land to the south.

Biological evidence with regard to the distribution of insect species supports these theories of former land-masses up to a certain point. For the Papuan insect fauna appears to be of oriental origin, showing decided affinities with the fauna of the Philippines, New Caledonia and the Moluccas; but is distant from that of Malaysia, with the exception of a few widely dispersed species which may represent a much older fauna.

The Papuan insect fauna has also spread in a south-easterly direction as far as the Society Islands in the mid-Pacific. I think that later we shall find the Papuan element in the Pacific even stronger than it appears, when we are more familiar with true Papuan forms and are in a position to check old records. For I have discovered in many cases that species recorded as Indo-Malayan, Austro-Malayan and Australasian are in reality Papuan; even so-called Australian species are very often those recorded from tropical Queensland and therefore are also Papuan.

The origin of the peculiar endemic fauna and flora of New Guinea, however, is not explained by the work of geologists. Old mountains of continental rock do exist in New Guinea, in the central ranges and to the north; but these have not been investigated, and may have been submerged before the Tertiary. On the north coast, however, where I recently made a collecting expedition on behalf of the British Museum (Natural History), the Cyclops Mountains and

Mt. Bougainville in Dutch Territory (Fig. 1), and the Torricelli Range in the Mandated Territory, are of pre-Cambrian schists and gneisses, and these mountains at least show no sign of submergence. They all belong to the same geological period and have a similar geological formation.

Before leaving England for Dutch New Guinea, I tried to obtain information of the topography of this region but without success. In Netherlands Indies the Dutch authorities showed me Government geological maps (not available in England), from which it is evident that no marine deposits have been recorded from the Cyclops Mountains or Mt. Bougainville. What is also very interesting is that they were evidently islands, the old shores of which can be traced inland. For inland south of the Cyclops Mountains—which are a coastal range thirty miles long—is a Tertiary limestone zone. In this area I discovered an old coral cliff more than 120 feet high. Rock specimens from this cliff which I brought back with me contain Tertiary Foraminifera; and a fossil reef-shell, *Strombus* sp. from the bank of a stream in that neighbourhood, is also Tertiary.

At the foot of the mountains on the south lies Lake Sentani, the southern shores of which are formed of elevated coral limestone—the old coast of the former island—and the bed of the lake has been raised 200 feet. The northern side of the range is high and steep, with cliffs sheer to the sea, and has no inlets or anchorage except the two bays east and west. It appears that the island tilted downwards on that side, but was raised on the south together with its fringing coral reefs. Mt. Bougainville farther east is also surrounded by old coral inland.

With regard to the Torricelli Range in the Mandated Territory, an oil company has been working for eight years in that district, and the mountains with the surrounding area have been thoroughly surveyed. The company does not wish to publish maps at this stage of its work, but I learnt from its members that they had come to the same conclusion regarding the Torricelli Mountains, namely, that this range was formerly an island, and there is no evidence of submergence.

This is extremely significant in the early history of the Papuan fauna. We see that there exist in New Guinea to-day at least three mountain groups —and doubtless there are others—which were formerly islands, and have remained above the sea throughout a very long period. It is interesting,

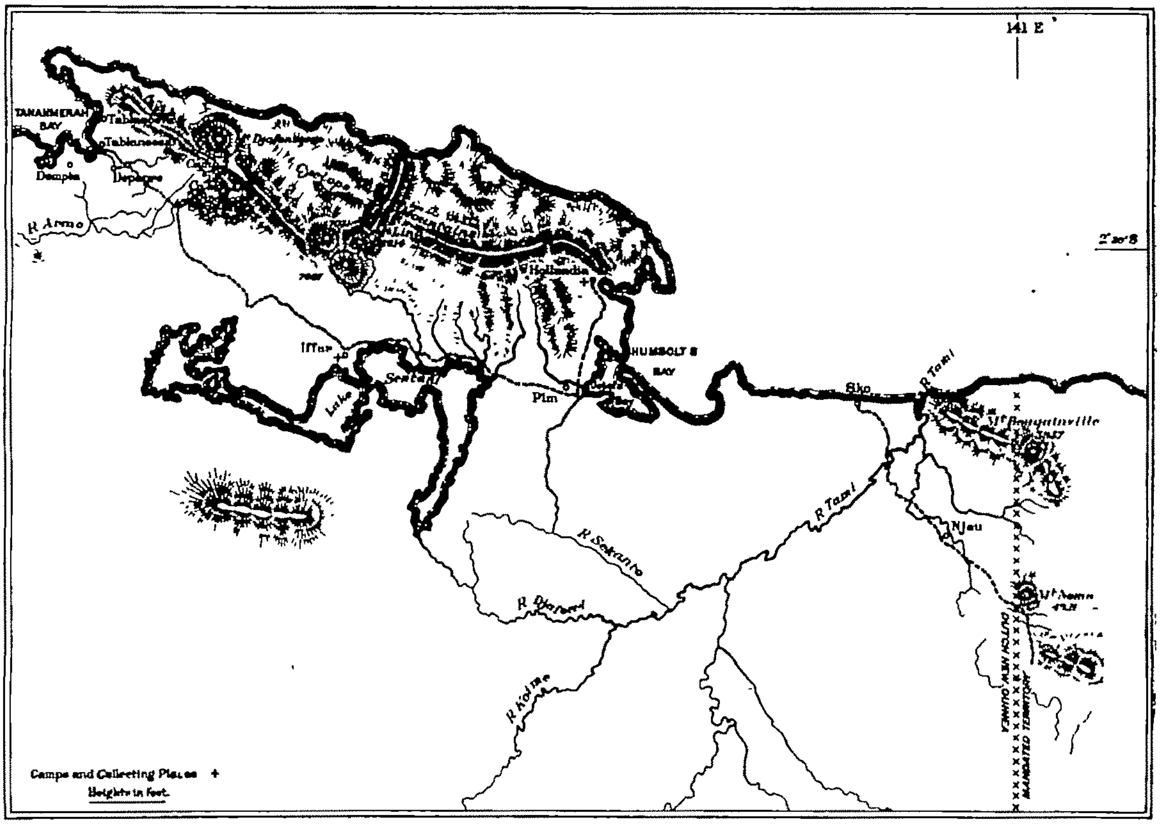

FIG. 1.

MAP OF THE BRITISH MUSEUM (NATURAL HISTORY) EXPEDITION TO THE NORTH OF NEW GUINEA too to note that they all have a similar trend, and that they correspond with the crystalline schists of the island of Japen and with those of a range south of the Arfak Mountains in Vogelkopf.

If we assume that New Guinea has not been entirely submerged since very remote ages, and that remnants of the Middle Cretaceous land-mass exist to-day, this is entirely consistent with geological as well as biological evidence. It is not fantastic to consider that the land which rose from the Eocene Sea would unite these old islands, and their population would spread over the new territory; and isolation upon islands would account for the richness of the Papuan fauna and flora.

The Papuan insect fauna is approximately one third Oriental and two thirds endemic. If we consider that this fauna consists of old forms of Oriental origin together with more recent forms derived from them, that appears to be a very plausible explanation, and provides a most helpful working hypothesis in tracing the affinities and the distribution of species.

Obituary Notices

Dr. S. F. Grace

SAMUEL FORSTER GRACE was born on May 10, 1895, at Huyton, near Liverpool. As a boy he attended St. Francis Xavier's College, Liverpool, where he had a very brilliant career. In 1908, 1910 and 1911 respectively he took the preliminary, junior and senior stages of the Oxford Local Examinations, and was awarded first class honours in all three. In each of the first two of these examinations he was placed "first in all England". In 1912 he entered the Faculty of Science of the University of Liverpool with valuable scholarships; and studied mathematics and physics. In 1914 he passed the examination for the ordinary degree of B.Sc., being the most distinguished student of his year in mathematics. At the outbreak of the Great War, he joined the King's Liverpool Regiment and was in France almost continuously until the summer of 1918. It was on the Somme in June 1918 that he received the wound which ultimately led to his death.

In the spring of 1919, Grace returned to the University of Liverpool and entered the honours school of mathematics. He took the honours degree in 1920 and, in spite of the gap of nearly five years in his studies, his record was one of the best which that particular school has ever had. During the session 1920–21 he worked at the Sorbonne and the Collège de France, holding scholarships which included an 1851 Exhibition Research Scholarship. In 1921 he joined the teaching staff of the Department of Mathematics of the University of Liverpool, and steadily progressed from the lowest to the highest grade of lecturers. He was a born teacher and had a power of getting to know the individual qualities of large numbers of students.

Before going to Paris, Grace began mathematical investigations on the motion of solids in a rotating liquid, the results of which were published in the *Proc. Roy. Soc.* between 1922 and 1926. He then began a series of researches on tides, the results of which were published in the *Geophys. Supp., M.N.R.A.S.* These fall into three groups on the following subjects: (1) The analysis of observational data with the object of finding the laws of internal friction in tidal currents, and the friction at the sea-bottom. (2) The theoretical determination of the distribution of the tides over the Gulf of Mexico and the Bay of Biscay. (3) The dynamical explanation of actual tides in narrow seas.

All Grace's research was marked by excellent workmanship. He had a steady-going persistence and thoroughness and a capacity for sustained hard work which carried him far.

From 1924 his war-wound gave him serious trouble, and he had several long and grave illnesses. During periods of convalescence and before he had recovered sufficiently to give his university lectures, he worked steadily at his researches. He died on April 30, immediately following an operation, and it was characteristic of him that he had taken some proofs into the nursing home, so as to be able to correct them on his recovery. He never married. J. P.

Dr. John Humphreys

By the death of Dr. John Humphreys, which occurred at Edgbaston on May 29, scientific and antiquarian circles in Birmingham have lost one of their most distinguished members. Born so long ago as 1850 at Llanfyllin, Montgomeryshire, he came from a family which in the previous century had given to the Church a bishop of Bangor and Hereford.

Entering the dental profession by apprenticeship—the only method possible at the time—Humphreys began to practise in Bromsgrove, but soon moved to Birmingham. In 1883 he joined the staff of the Birmingham Dental Hospital, and with the introduction of a dental curriculum at Queen's College became lecturer on dental anatomy. After the incorporation of Queen's College and Mason College in the University of Birmingham in 1900, he continued in the lectureship, which he retained until his retirement from active professional work in 1919. During the tenure of this appointment the claims of a large practice allowed little time for research, but in collaboration with his life-long friend Dr. (later Sir) B. C. A. Windle, he contributed several papers to scientific journals, of which one on "Man's Lost Incisors" and another on "Some Cranial and Dental Characters of the Domestic Dog" are particularly noteworthy. At the same time that he was thus engaged, he began to collect specimens to illustrate his lectures, succeeding to such an extent that he ultimately could claim to possess the most complete and valuable private odontological collection in Great Britain—a collection which with characteristic generosity he presented to the University on his retirement.

Although it is safe to say that this gift alone will serve to perpetuate his memory, Humphreys has many other claims for remembrance. By his survey of the glacial boulders in the Birmingham district, he has added appreciably to our knowledge of the ice-movements in that locality during the Pleistocene period, while by his presentation to the Birmingham Natural History Museum of a complete collection of the flora of east Worcestershire he has placed all lovers of that part of our countryside under a deep and permanent debt of gratitude. His work in these two directions was recognized by his election to the fellowships of the Geological and Linnean Societies.

In later years, Humphreys became more and more interested in antiquarian subjects, serving on the council of the Society of Antiquaries and acting as local secretary for Warwickshire and Worcestershire. He took an active and prominent part in the recent excavations at Uriconium and in the exploration of the Anglo-Saxon cemetery at Bidford-on-Avon, which latter was conducted with such care that it has been said "not a bead was lost". He traced, again with a wealth of topographical detail, the movements of the conspirators in the Gunpowder Plot on their dramatic flight from London to their last stand at Holbeach. He succeeded after a search, extending over three years, of the manor houses of the Midlands in finding in the butler's bedroom at Chastleton House near Moreton in Marsh several priceless Elizabethan Sheldon tapestries, two of which are now among the glories of the Victoria and Albert Museum and the Birmingham Art Gallery. Scarcely less dramatic was his discovery of the important "Bowery Papers" in a leather-covered wooden chest in a windowless attic at Cleeve Prior, where they had lain for more than two centuries. In 1924 the University of Birmingham, which had at various times conferred upon him the degrees of master of arts, doctor of philosophy and master of dental surgery, elected him to a readership in mediaeval archæology.

That Humphreys was able to accomplish so much, even granted his length of days, was due to exceptional ability and industry, and perhaps even more to tenacity of purpose. Great as these qualities are, it is for other and rarer qualities that his many friends will chiefly remember him—his wide sympathies, his unaffected friendliness, his complete disinterestedness. No one ever practised with greater persistence and success the gentle art of self-effacement. W. W.

Mr. J. H. Field

THE scientific work of Mr. J. H. Field, whose death on May 19 at the age of sixty-four years is much deplored, was of a type none the less valuable because it was mainly practical rather than theoretical. He had qualified in physics and engineering at Cambridge and London, and was selected in 1904 for the Indian Meteorological Department to initiate upper-air work. He threw himself wholeheartedly into the task: regardless of hardships, such as those of the Northwest Desert in the hot weather, he adapted Western methods of getting data by kites and balloons to Indian conditions; the instrumental and mechanical equipments were largely designed and constructed by himself.

Financial difficulties were at first acute; but in 1912 matters improved and Field started the Agra observatory, which developed into a factory for making and compressing hydrogen, a workshop for making instruments, and a mother-station for a number of pilot-balloon observatories. In 1924 he took on the less congenial post of head of the Department; and for five years there he showed the enthusiasm and the tireless thoroughness that had always marked his activities. On his retirement he was responsible for a complete and able examination of the conditions that led to flying accidents in the lee of the Rock of Gibraltar.

Field's scientific papers consist mostly of data and discussions of the upper-wind system of India. He also carefully studied the exposure of thermometers at the ordinary observing stations. Perhaps his chief discoveries were the thinness of the monsoon currents in north-west India and the great increase of strength in the upper winds in the cold weather. He found also a marked tendency for an unusually vigorous increase to be followed by an unusually vigorous winter rainfall: here he always recognized that he had not data enough to justify reliable conclusions, but since his retirement this criterion has become the most reliable of the five criteria used in the winter forecast.

Field's real monument is the upper-air observing system of India, with about thirty-six observatories, and its well-designed equipment of instruments; but he secured also a new headquarters building at Poona. He will long be remembered by his staff for the inspiration of his indefatigable thoroughness and for the justice of his rule. G. T. W.

WE regret to announce the following deaths:

Prof. J. A. Culler, emeritus professor of physics in Miami University, Ohio, on May 18, aged seventy-nine years.

Sir Squire Sprigge, editor of the *Lancet* and author of "The Life and Times of Thomas Wakley" (1896), "Medicine: Its Practice and Public Relations" (1905), "Some Considerations of Medical Education" (1910) and "Physic and Fiction" (1921), on June 17, aged seventy-six years.

Prof. H. E. Slaught, emeritus professor of mathematics in the University of Chicago, on May 21, aged seventy-six years.

News and Views

Royal Society Elections

AT a meeting of the Royal Society held on June 17, the Right Hon. the Earl of Athlone was elected a fellow of the Society under a special clause in the statutes which provides for the occasional election of "persons who either have rendered conspicuous service to the cause of science or are such that their election would be of signal benefit to the Society". At the same meeting the following were elected foreign members of the Society: Prof. August Krogh, of Copenhagen; Prof. Otto Meyerhof, of Heidelberg; and Prof. Henry Norris Russell, of Princeton.

Prof. August Krogh

THE election of Prof. A. Krogh to the Royal Society will give much pleasure to his many friends, who have been following with great admiration his remarkable achievements in different branches of physiology. His early work (1904) in collaboration with Bohr and Hasselbach demonstrated for the first time the effect of carbon dioxide on the affinity of hæmoglobin for oxygen. In 1910 Krogh definitely proved that the absorption of oxygen and the elimination of carbon dioxide in the lungs take place by diffusion only and without the assistance of any secretory activity by the cells. This investigation finally settled the long-standing controversy around this problem. We owe to Krogh a series of important contributions to the study of the respiration of insects and the elaboration of a delicate technique for the accurate analysis of minute bubbles of gas. This technique was applied ultimately to the study of problems in other fields of physiology. Krogh's remarkable work on the capillary circulation, which was soon recognized by the award of the Nobel Prize in Physiology and Medicine, is marked by the same insistence on direct proof, combined with a broad biological outlook. The work of Krogh's laboratory to-day is largely concerned with the problems of respiration, especially at high altitudes, problems of circulation, the mechanism regulating the water and salt exchanges in aquatic animals, and the ecology of aquatic organisms in relation to the nitrogen cycle in water.

Prof. O. Meyerhof

WE owe much of our present knowledge concerning the chemistry and thermodynamics of muscle to Dr. Otto Meyerhof. During twenty years he has published a remarkable series of papers—more than a hundred in all—describing experimental studies of the complicated events involved in the maintenance and activity of the contractile tissue. If our knowledge of these is yet incomplete, a survey of Meyerhof's papers alone will show that progress has been real and that his own work has done much to accelerate it. Twenty-five years ago, Meyerhof, who had been a student of psychiatry and philosophy, influenced by Otto Warburg—who himself became a foreign member of the Royal Society in 1934—turned to biological studies. He first dealt with cell respiration and, among other contributions to knowledge of this, showed that respiration calls for the influence of a soluble agent similar to the cozymase which Harden had shown to be a necessary factor in fermentation. To-day we have come to recognize how significant are these relations. By 1919, Meyerhof had begun to give special attention to muscle, and his earlier chemical and calorimetric studies ran parallel with the myothermic studies of A. V. Hill in Great Britain. This association became very enlightening, especially in bringing to light the time relations of events which occur during and after a contraction. Since then, Meyerhof and his school have described many improvements in technique, and have revealed many significant facts. Of special interest was the proof that the anaerobic breakdown of glycogen to lactic acid which occurs during a contraction is reversed during the aerobic process of recovery; and also the discovery—of much help to himself and to other workers—that many of the significant reactions which occur in the intact muscle proceed in due sequence in a properly prepared aqueous extract of the tissue.

Prof. H. N. Russell

PROF. H. N. RUSSELL, professor of astronomy at Princeton University, U.S.A., is one of the best-known American astronomers. He first became prominent through his theory of stellar evolution, according to which a star, contracting continuously throughout its history, passed successively through a 'giant' stage of rising, and a 'dwarf' state of falling, surface temperature. This theory, regarded somewhat sceptically at first, gained general acceptance through the discovery, by means of Adams and Kohlschutter's spectroscopic method for determining absolute magnitudes, of the reality of the distinction between giant and dwarf stars. The development of the theory of stellar constitution called for some amendment of the original postulates of Russell's theory, and it is characteristic of him that he made no attempt to preserve ideas based on insufficient data, but became a leader in the reformulation which was seen to be necessary. He was among the earliest to realize the importance of Saha's theory of ionization in stellar atmospheres, and took a leading part in working out its implications, always with a keen appreciation of the limitations placed on theoretical possibilities by difficulties inherent in methods of observation. The development of laboratory spectroscopy attracted him strongly, and with the collaboration of Prof. F. A. Saunders he obtained the first evidence of the co-operation of extra-nuclear electrons in producing line spectra: 'Russell-Saunders coupling' is now a well-established, and the most frequently occurring, type of such co-operation. More recently he has made important contributions to the analysis of complex spectra corresponding to various stages of ionization—particularly those of metals prominent in celestial spectra.

PROF. RUSSELL's work is marked throughout by a breadth of interest and a clearness of apprehension of essentials which place him among the greatest men of science of the time. There is scarcely a branch of astronomy (with the possible exception of problems peculiar to the extra-galactic nebulæ) which has not attracted his attention and become elucidated thereby. He has recently advanced some very suggestive ideas relating to the origin of the solar system, and his text-book on astronomy, written in association with his colleagues, Profs. R. S. Dugan and J. Q. Stewart, is unique in its kind. He travels freely among the American observatories, and has for many years been regarded as a kind of unofficial ambassador-at-large, co-ordinating work of various types and often taking an active part in the solution of the problems encountered. His vivid personality is one of the most conspicuous and characteristic features of astronomical conferences, and the well-deserved honour now accorded him of foreign membership of the Royal Society will give universal satisfaction.

The German Expedition to Nanga Parbat

EVERYONE must sympathize with the Germans who have met with disaster, for a second time, in an attempt to climb Nanga Parbat. In 1934 three members, including the leader, lost their lives on the mountain in a blizzard and one died from illness; added to this, six of their faithful porters also lost their lives. Now news has come that the second German expedition has met with an even greater disaster, seven out of nine members, including the leader, Dr. Karl Wein, together with nine porters, having been overwhelmed by an avalanche at Camp IV. Details of what exactly happened are not yet to hand, but almost at the same time as the news of the disaster was telegraphed an article appeared in *The Times* of June 22 from Dr. Karl Wein, professor of geography at the University of Munich, dated June 6 from the Base Camp. From this it seems the present expedition is following the same route as that of 1934. On June 5 it had reached Camp III, which in the former expedition was at a height of 19,400 ft., while the 'trek' to Camp IV, 20,300 ft., had been made on the following day. In this account Dr. Wein describes a great avalanche crashing down the face of Nanga Parbat, but which with the exception of several stray fragments did not reach Camp II, 17,550 ft., which was being pitched at the time. The rush of air caused tents to be "blown over, tent poles snapped and strong canvas torn". All the members of the party seem to have been thoroughly experienced mountaineers. We shall await with interest details of this, probably the greatest, of Himalayan disasters.

Powers of the National Trust

THE Bill by which it is proposed to extend the powers of the National Trust was considered by the Select Committee of the House of Commons on unopposed Bills on June 17, Capt. R. C. Bourne being in the chair. The object of the Bill is to put into operation the scheme of the Trust for the preservation of houses of historic or æsthetic interest in private ownership, which in part was inspired by legislation framed for this purpose in France. It will enable the Trust to take over and save from breaking up large country houses and estates, while allowing the donor and his family and descendants to continue to occupy, provision being made for the public to have access to them. In addition, the Bill provides for enabling the National Trust to acquire and hold small sites of five acres in extent for the purpose of preserving "view-points"; to enter into agreements with owners restricting the use of land, and empowers local authorities to co-operate with the Trust. By this legislation the National Trust will be placed in a much stronger position in regard to what must be regarded as its most useful function—the safe-guarding and ensuring the preservation of sites which on account of their outstanding archæological, historical or æsthetic interest, are of national, or even of international importance. It will be relieved in no small measure of the constant necessity of urgent and hurried 'last-minute' appeals, which recent rapid land development has made unavoidable, but of which in the end there is danger that the public may become a little weary. The Trust will now be enabled by the Bill to concentrate on appealing to the general public for the preservation of sites of which the national importance will be most readily appreciated, or for which no other provision is possible.

Indians of Canada

AN example of the variation in method in dealing with the less advanced races of different parts of the Empire, to which reference is made on another page of this issue of NATURE (see p. 1083), is afforded in a recent survey of conditions among the Indians of Canada by the Hon. T. A. Crerar, M.P., Minister of Mines and Resources of the Dominion of Canada. Indian administration in Canada is dominated by the twofold aim of protection and advancement. The Indians, at one time rapidly decreasing in numbers and regarded as a doomed race, are now on the up-grade. Since 1927, when they had fallen to 104,000, they have increased to 112,000. This increase is attributed largely to the improved medical benefits they now receive and the greater attention given to hygiene. They live on reservations, of which there are two thousand of varying size, running from a few acres up to five hundred square miles, the total area being 5,170,000 acres, of which 220,000 acres is under cultivation. A fund of fourteen million dollars, accruing from the sale of Indian lands, mining rights, etc., is administered by the Government entirely for Indian benefit. The cultural condition of the Indians depends almost entirely on their geographical environment. In the East, they are farmers, and although many are very poor and all suffering from the effects of the economic depression, they differ little in condition from their white agricultural neighbours. In the northern hinterland they are hunters and trappers, and have suffered severely from white competition, and the same applies to some extent to the salmon fishing communities of the North-West coast; but the tribes of the Plains region (Alberta) who lost their livelihood with the extinction of the bison and became farmers and ranchers, have in many instances achieved prosperity in two generations. Finally, it may be added, it is possible for an Indian to become enfranchised on certain conditions, and to cease to rank legally as an Indian.

Statistics of Unemployment

THE report of the Ministry of Labour for 1936 directs attention to the exceptionally sharp rise in the numbers available for employment, which increased by 270,000 between July 1935 and July 1936, due mainly to a rise in the numbers of persons aged sixteen years resulting from the increased birth-rate in the immediate post-War years. Against this there was a large increase in the numbers in employment, which in December 1936 reached the highest level recorded since comparable statistics have been kept—11,132,000 as against 10,629,000 in December 1935. There was also a marked decrease in the numbers unemployed, the number of persons registering as unemployed at employment exchanges in December 1936 being 1,629,000 as against 1,869,000 in December 1935. This total includes 69,000 'casuals', 195,000 'temporarily stopped' and 82,000 'juveniles'. Analysis of the age distribution of unemployed men and women indicates that the problem of finding work for those in the older age groups is predominantly one affecting men, and that age proves a handicap to obtaining employment when younger persons are available. Severe unemployment continued in the coal mining industry, but on a lower level than in 1935. The position improved in all the metal trade groups; in the cotton industry, unemployment over the whole year was 15·7 per cent compared with 20·9 per cent in 1935. The position improved in the wool industry but remained severe in the jute industry and in textile finishing. Most other industries showed improvement.

THERE was a marked increase in the number of persons transferred from the depressed areas compared with previous years, and the proportionate increase in the number of families assisted to re-settle was even more notable. In view of the improved employment position, the whole country was thrown open in instructional centre recruitment, preference in allocation to centres being given to men from areas of heavy and prolonged unemployment. Some expansion in physical training is also reported. Juvenile employment conditions also improved, but there was no indication of a general revival of the apprenticeship system of engaging labour. Shortages of juvenile labour relate particularly to boys and girls in the 14–15 age group, and there was a widespread tendency to raise the starting wage of learners, particularly in unskilled and non-progressive employment. The policy of industrial transference of juveniles was continued in certain areas, as well as arrangements for vocational training and guidance and placing in employment. Reference is also made to progress in the decentralization of the work of the Ministry.

Russian Trans-polar Flight

THREE Soviet airmen, flying a single-engined 960 h.p. monoplane, "Ant 25", left Moscow on June 18 on a non-stop flight to San Francisco via the North Pole. According to the New York correspondent of *The Times*, they were compelled by poor visibility to land at Pierson Field, Vancouver Barracks, in the State of Washington, on June 20, when within six hundred miles of their goal. They had been in the air for 63 hours 17 minutes, and are stated to have passed near the Pole at an altitude of 14,000 ft. The three airmen, MM. Byelyakoff, Chkaloff and Baidukoff, have been decorated with the Soviet Order of Merit, and Mr. Roosevelt, in a congratulatory message to the Soviet Ambassador in the United States, referred to the flight as a "historic feat".

Palæolithic Implements from Bombay

PALÆOLITHIC implements from the island of Salsette, north of Bombay, of considerable importance as demonstrating for the first time the presence of a palæolithic culture in this region of India, have been placed on exhibition in the British Museum (Bloomsbury). This series of implements is the result of three years' excavations carried out by Lieut.-Commander Todd in Pleistocene deposits of alternating gravel and clay. The implements are of indurated shale and come from various levels of stratification. They include Lower, Middle and Upper Palæolithic types, which, however, differ considerably from previous palæolithic finds in India. The principal site is a quarry at Khandivli, situated some 100 ft. above sea-level near the foothills running up to the mountainous interior. Mesolithic implements occur as surface finds and also in the caves of Padan not far away, where they are associated with rock engravings. Diagrams of the geological conditions and photographs of the sites are also exhibited with the implements.

Research on Diseases of Farm Animals

AN extensive programme of investigation into the cause and prevention of disease in farm animals is being undertaken by the Animal Diseases Research Association at Moredun, near Edinburgh, under the direction of Dr. J. Russell Greig. It has for some time become apparent that the existing laboratories and animal accommodation at Moredun were insufficient for the Research Association's rapidly extending work, and Treasury sanction has recently been given to the recommendation of the Agricultural Research Council and the Department of Agriculture for Scotland that a grant not exceeding £9,800 should be made available (after taking into account any receipts from other sources) from the Development Fund to enable necessary building extensions to be undertaken. In view of the economic importance of grass sickness, it became clear to the Department of Agriculture for Scotland and the Agricultural Research Council that further extension and intensification of the research into the cause and prevention of this disease are necessary, and the Treasury has sanctioned an appropriation from the Development Fund to the Department of Agriculture for Scotland of a sum not exceeding £3,200 to meet the expenditure for extended work on this disease during the current financial year. Several contributions towards the cost of grass sickness investigation have been received from outside sources, notably that from the Racecourse Betting Control Board, which has granted £1,000 for the work at Moredun during 1937. While the cause of this fatal disease, which is reported to have killed 1,200–1,500 horses last summer and is by no means confined to Scotland, is suspected to be due to poisoning developed in the intestine by certain bacteria, taken in on grass or in some other way during feeding, this theory, though promising, is not yet proved. A large-scale vaccination trial, which is being made after careful preliminary experiments, is intended as a further test of this theory.

General Science and Education for Citizenship

PROF. LANCELOT HOGBEN's address on "The Teaching of Science in the Education of the Citizen" delivered at a conference of higher education members of the National Union of Teachers on December 30 has now been made available in pamphlet form (London: National Union of Teachers). There is much that is controversial in the address, and the Union is careful to disclaim responsibility for its views and opinions; but its provocativeness is stimulating. It starts from the position that the social task of modern education is "to implement the age of plenty. To do it we have to make the record of scientific discovery an open Bible". In the teaching of science should be epitomized the drama of human achievement, and at each stage the question "Did this or that principle, this or that theory, help mankind to lift this or that stone in the building of the temple of plenty?" will serve to discriminate between the essential and the non-essential constituents of any proposed curriculum and to reconcile the competing claims of specialists. But how about preparation for passing examinations designed by specialists without regard to the requirements of intelligent citizenship? Will students taught on these principles be able to cope with them? Will not those who are themselves destined to become specialists suffer?

To these questions, Prof. Hogben gives answers based on his own teaching experience. The keen interest aroused by the approach to science as a social venture, and the framework of important facts and comprehensive principles provided by it make the memorizing of the less vital facts needed for passing examinations an easy matter and make a sound basis for later specialization. A fatal error in the teaching of science is the presentation of principles without regard to a sufficient background of relevant information. Prof. Hogben finds an illustration of this in present methods of teaching electricity and magnetism. He advocates a greatly extended use of films in the teaching of science. The cinema, he says, can bridge the gulf which now separates people who have a good visual imagination from those who have not.

New Power Station on the Rhine

IN the *Escher-Wyss News* of December, published by the well-known engineering works at Zurich, a complete description is given of the Albbruck-Dogern Power Station on the Rhine. The Rhine, which historically has played an outstanding part among the rivers of Europe, has gained appreciably in commercial importance during the last ten years. Formerly its importance depended on navigation, which gradually spread up the river from the Niederrhein to Basle, now a port handling more than 2·2 million tons annually. During the last ten years the utilization of the water-power has proceeded in the opposite direction from the Upper Rhine down the Rhine valley. The part of the river of greatest interest as regards power generation is that lying between the Lake of Constance and Strasbourg. This stretch extends about a hundred miles, and if we exclude the sudden drop at the Rhine Falls, the gradient is about 1 in a 1,000. There are now eight, including the latest, the Albbruck-Dogern, low head water-power stations erected along this stretch of the Rhine.

FOR the complete utilization of the Rhine six further stations are projected. The installed output of all the stations together will amount to approximately one million horse power, and the average yearly generation of electricity will be about 5,000 million kilowatt hours. With the exception of the French station at Kembs, all the stations have Escher-Wyss water turbines. The new station at Albbruck-Dogern utilizes the flow from the head of the Rhine to the lower course of the Aare as far as the Klingnau power station. The water supplied by the head race has an average flow of 900 cubic metres per second. It is utilized in three vertical shaft turbines each of which is capable of developing 37,600 h.p. under a head of 11·5 metres and with a maximum flow of 290 cubic metres per second. The power station is at Albbruck and has a length of 87 metres and a breadth of 29·3 metres. The three sets, each consisting of a water turbine and an electric generator, are arranged in a row at right angles to the canal and 27 metres apart. After passing through a transformer the electric energy is transmitted at 104 kilovolts.

Prepayment Electricity Metres

THE prepayment meter is, in general, suitable for the user of electricity whose means are small. The advantages are that he pays in small amounts and that he has an incentive to check and control running costs. The disadvantages are that he pays slightly more per unit consumed, and the supply is apt to be interrupted at inconvenient times. To the supply company, the advantages are that there is less accounting as there are no bills, there is a reduction in bad debts, and special applications can be used in hotels and boarding houses. On the other hand, the reading and collecting cost is increased and so also is the maintenance. Mention of coin mechanisms in connexion with measuring holy water began about A.D. 200. A history and criticism of various types of 'coin mechanisms' in connexion with electric meters are given in a paper by J. Prince and M. Whitehead read to the Institution of Electrical Engineers on April 2. Most of the difficulties in connexion with these meters, including the prevention of fraudulently tampering with them, have now been overcome. One of the outstanding points which affect the use of coin mechanisms is the psychological reaction of the peoples concerned. According to the authors, there is a definite objection to prepayment in both Canada and the United States. They are not used in Denmark, France and Portugal. A few are in use in Holland, Austria, Switzerland, New Zealand and Italy. Great Britain seems to be the only country in which there is a great demand for prepayment meters; probably because it provides the best means of promoting the use of electricity among people of small means.

Journal of the University of Manchester

FROM the University of Manchester we have received a copy of the University's *Journal*, No. 1, vol. 1, published by the Manchester University Press. In an inaugural message from the chairman of Council, Sir Christopher Needham, the *Journal* is described as a new venture designed by the Council to meet what it feels to be a responsibility in regard to graduates, to provide news of University interest and information of developments in University policy as well as personal matters. Conversely, an article by Mr. David Cardwell, chairman of Convocation, reminds graduates that active membership of Convocation (which has, since 1915, followed automatically on graduation) affords a means of service whereby the life-long debt they owe to their University may, in some measure, be repaid. The realization of this ideal has been facilitated by the formation of Groups of Convocation formed in Manchester, London, Leeds and Sheffield and contemplated at Oxford, for discussing matters of University interest and such social and other activities as their members may desire. Sir Ernest Simon contributes an article, "A Time for Expansion: the New Buildings and the Future", describing buildings just completed at a cost of £100,000, others (including a new dental school and hospital and physical chemical research laboratory, swimming bath, etc.) which it is hoped to complete by the end of 1938, and a project, illustrated by an architect's drawing, for further urgently needed developments destined to form with the buildings already mentioned a dignified and impressive quadrangle. Among other contributors to the journal are: Prof. A. H. Gibson (on the Department of Engineering), Prof. Edward Fiddes (on "Some Teachers of Owens College"), Dr. Tyson (on "The Library and its Uses") and Prof. G. H. Thompson (his Ludwig Mond lecture on "Intelligence and Civilisation"). Copies of the *Journal* will be supplied without charge and on application, to graduates and friends of the University.

Dr. H. L. Richardson

DR. H. L. RICHARDSON, of the Chemistry Department, Rothamsted Experimental Station, has been appointed adviser in soils and fertilizers to the National Agricultural Research Bureau, Shaolingwei, Nanking, China. This institution, which was founded in 1931, possesses extensive laboratories and a farm of 400 acres, and has already made great progress in the investigation of crop production, plant diseases, animal production, and crop recording. In addition to conducting experiments at Nanking, it works in close collaboration with the numerous provincial research stations in China. Dr. Richardson received his training at Victoria University College, New Zealand, and the University of London, and joined the Rothamsted staff in 1927. He has been particularly associated with the developments in soils and fertilizers.

Indian Institute of Science

IT is reported from Bangalore that, at a meeting of the Governing Council of the Indian Institute of Science held on June 1, Sir C. V. Raman decided to sever his connexion with the Institute. The Council proposed that he should continue in the Institute as professor of physics without administrative powers, and suggested the appointment of an interim director to administer the affairs of the Institute pending the appointment of a new director. Sir C. V. Raman declined the offer of the Council and was unwilling to continue as a subordinate to any other director. It was recommended by the Irvine Committee that a registrar should be appointed to relieve the director of administrative duties and to be directly responsible to the Governing Council. Early this year, it was reported that Mr. R. H. Beckett had been appointed registrar of the Institute, but we understand that, though he was offered the post, he did not accept it. We are now informed that the registrar will be Mr. C. E. W. Jones, C.I.E., lately director of public instruction, Central Provinces.

Chemical Engineering Exhibition in Germany

ANNOUNCEMENTS have been issued of the meeting in Frankfort-on-Main during the week July 2–11 of the various bodies in Germany concerned with chemical engineering and the holding at the same time of the Eighth Chemical Engineering Exhibition, widely known as the "Achema". At the last Achema Exhibition, held in Cologne in 1934, an impressive picture was given of the high standard of production of chemical engineering plant and apparatus in Germany and the exhibition attracted 49,000 visitors.

In the interim, the importance of this branch of industry has increased all over the world and in addition there has been an unprecedented industrial development in Germany brought about by the planned transformation of the national economic system. It is expected, therefore, that the Exhibition next July will offer unusual opportunities and that it will attract a large number of expert visitors from all parts. The Achema Bureau is located in Berlin, W.35, Potsdamerstrasse 103a.

Proton-Neutron Exchange Interaction

REFERRING to his letter in NATURE of June 12 (p. 1021), Mr. H. J. Bhabha states that he omitted to insert the following at the beginning of the final paragraph: "The above experiment may be done with cosmic rays, but it must be emphasized that we do not know that the penetrating group consists of protons, even though we know it cannot consist of electrons obeying the theory."

The Night Sky in July

THE duration of darkness is too short this month to scan a number of interesting objects. Mars, Jupiter and Saturn are to be seen, followed by Venus, which is a bright morning star. On July 17 at 21^h U.T. ($= 22^h$ summer time), Mars is in conjunction with the moon, and an occultation is visible from Great Britain. The disappearance of Mars behind the moon as seen from Greenwich takes place at $21^h\ 17{\cdot}7^m$ and the reappearance at $22^h\ 19{\cdot}8^m$. Jupiter is in opposition on July 15; its equatorial diameter is $47\frac{1}{2}''$ and its polar diameter $3''$ less, the oblateness of the disk being apparent in quite a small telescope. On July $22^d\ 21^h$, Jupiter is in conjunction with the moon. The configurations of the four inner satellites of the planet are given for $23^h\ 45^m$ in the Nautical Almanac of 1937, p. 625. Saturn with its ring system is, of course, nearly always an attractive object for observation with a refractor of 3 inches aperture or larger. The planet is stationary amongst the stars on July 18. The moon is new on July 8 at $4{\cdot}2^h$ and full on July 23 at $12{\cdot}8^h$. The occultation with Mars when the moon is $9{\cdot}7^d$ old has been mentioned above. On July 31 a conjunction of Mercury with the bright star Regulus may be noted. The planet is only 0·4° north of the star (geocentric positions). About midnight (23^h U.T.) in the middle of the month, a bright and interesting stretch of the Milky Way is passing the meridian of London. The Constellations Scorpio, Sagittarius, Aquila, Cygnus (south of the zenith) and Cassiopeia, Perseus and Auriga (to the north) mark its span. In latitudes somewhat farther south than that of London, the galactic star clouds in Scorpio and Sagittarius are an unforgettable sight which may be guessed at on clear moonless nights in Great Britain. Though less spectacular, the low eastern sky at midnight contains the constellation Andromeda, and by locating the great nebula, which can be done with the unaided eye, we are seeing out to the depths of space beyond our galactic system. A number of meteor radiants are active during July, among which may be noted the $\alpha\beta$ Perseids with radiant at R.A. $3^h\ 12^m$: Dec. 43° N.; γ Draconids (radiant, R.A. $17^h\ 56^m$: Dec. 48° N.) and the δ Aquarids (radiant R.A. $22^h\ 36^m$: Dec. 11° S.). Some swift meteors may be seen from the radiant at R.A. $21^h\ 0^m$; Dec. 48° N.—the α Cygnids.

Announcements

H.M. THE KING has nominated Sir Arthur MacNalty to be for five years a member of the General Council of Medical Education in the United Kingdom in succession to Sir Henry Dale.

THE following awards from the Lady Tata Memorial Fund for research in blood diseases, with special reference to leukæmia, have recently been made: *Grants for research expenses*, Dr. Julius Engelbreth-Holm (Copenhagen), Prof. Karl Jármai (Budapest), Prof. James McIntosh (London), Prof. Charles Oberling (Paris), Prof. Eugene Opie and Dr. Jacob Furth (New York), Dr. Georg Weitzmann (Leipzig) and Dr. Lucy Wills (London); *Scholarships*, Dr. Jørgen Bichel (Aarhus, Denmark) and Dr. Edoardo Storti (Pavia, Italy).

A CONFERENCE on the "Challenge to Democracy" will be held at Ashridge College, Berkhamsted, by the Association for Education in Citizenship, on July 8–14. Further information can be obtained from the Secretary, Association for Education in Citizenship, 10 Victoria Street, S.W.1.

AN earthquake of moderate intensity was recorded at Kew Observatory on June 21. The first impulses were registered at 15 hr. 26 min. 2 sec. G.M.T. The records indicate that the shock was located about 6,000 miles away, probably in Peru.

PROF. HUGO SPATZ has been appointed director of the Kaiser Wilhelm Institute for Cerebral Investigations.

AN international congress of public health consisting of ten sections will be held in Paris on July 1–10. Further information can be obtained from the Secrétariat Général, Laboratorie d'Hygiène, Faculté de Médecine, rue de l'Ecole de Médecine, Paris, 5^e.

THE Belgian Government has decided to organize a campaign of health with the title of the National Crusade of Health under the direction of the Red Cross.

DR. MAX WIEN, professor of physics at Jena, and Prof. Oskar Seyffert at Dresden, have been awarded the Goethe Medal for art and science by the German Chancellor.

THE first World Congress on the Voice, organized by *Euphonia*, will be held at La Maison de la Chimie, Paris, on September 19–28. Further information can be obtained from Dr. Wicart, 92 Avenue de Wagram, Paris.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1113.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Growth Substances, Root Production, and Cambial Activity in Woody Cuttings

IT is now well established that α-naphthalene acetic acid and β-indolyl acetic acid (heteroauxin) are among the most active chemicals which stimulate the production of roots[1]. In fact, these substances are put to practical use in accelerating the production of roots from cuttings, herbaceous or woody[2].

Whilst testing numerous horticultural plants, including species well known to root readily and others more reluctant to do so, examples have been encountered of the stimulation to marked activity of the cambium. The following illustrate this phenomenon seen at various seasons of the year:

(1) Cuttings of *Viburnum Carlesii* were taken in mid-July and placed with their basal ends in a solution of α-naphthalene acetic acid, and others in β-indolyl acetic acid, of a concentration of 1 part in 10,000 of distilled water for twenty-four hours; controls were placed in distilled water. The period of uptake of the solution, due to transpiration in part at least, was terminated by washing in water. Insertion into sand in a propagating frame immediately followed the treatments. Within fourteen days the bark of the treated cuttings was seen to split owing to the rapid formation of new tissues inside. Many roots emerged in twenty-one days; frequently these were formed in rows.

(2) Similarly, cuttings of *Ceanothus dentatus* taken on November 28 and treated as already outlined, responded by the rapid production of a new cylinder of tissue of a thickness of some twenty cells, counted radially. These were formed in less than five weeks. Medullary rays in this tissue, stained deeply, are readily seen in the transverse section (Fig. 1).

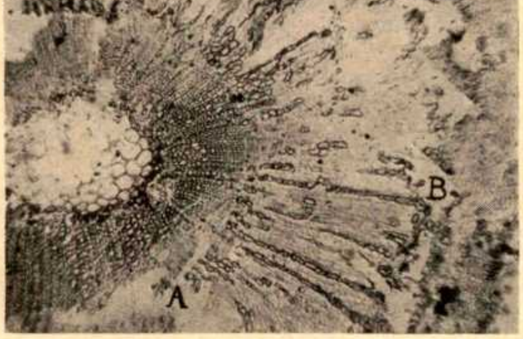

Fig. 1.

TRANSVERSE SECTION OF THE STEM OF *Ceanothus dentatus* AFTER STIMULATION BY ALPHA NAPHTHALENE ACETIC ACID (NOV. 28, 1936). SECTION CUT JAN. 22, 1937. THE REGION *A* TO *B* SHOWS THE NEW PARENCHYMA WITH MEDULLARY RAYS. ×60 DIAMETERS.

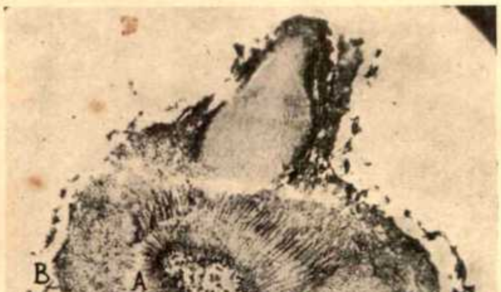

Fig. 2.

TRANSVERSE SECTION OF *Myrtus communis*, STEM SHOWING THE DEVELOPMENT OF ROOTS. IN THE REGION *A* TO *B* PARENCHYMA HAS DEVELOPED OUTSIDE THE XYLEM, AFTER STIMULATION BY ALPHA NAPHTHALENE ACETIC ACID (JAN. 12, 1937). SECTION CUT FEB. 19, 1937. ×30 DIAMETERS.

(3) With *Myrtus communis* a concentration of two parts in 10,000 of α-naphthalene acetic acid for twenty-four hours was used with cuttings taken on January 11. Rapid cell division afterwards took place resulting in new tissue of a thickness of fifteen to twenty cells, counted radially. Where roots developed, and they were freely formed, as may be seen from Fig. 2, the number of new cells produced radially far exceeded that number.

(4) With *Tricuspidaria dependens* taken in late January, the rate of cell division in the treated series has been observed to be remarkably rapid—a cylinder of a radial thickness of eighteen cells has been formed in twenty-five days.

The control cuttings did not show this activity. In them the production of callus tissue was localized, and limited to the base of the cutting. Generally, in the treated cuttings the rate of cell differentiation and lignification of the new tissue did not keep pace with that of cell formation, resulting in tissue of a parenchymatous nature almost entirely undifferentiated, as is well shown by longitudinal sections. The region of stimulation varied in position and length, but frequently was limited to 1·5–2 cm. and did not usually extend to the base of the cutting. An 'internal tube of callus' of cambial origin was produced. Thus it was not only a question of the development of root initials previously laid down.

Full anatomical details are not yet available, but the possibility is not precluded that repeated cell divisions took place to form cells in an irregular and intercalary manner as distinct from the more regular centripetal and/or centrifugal abscission usually associated with cambial activity.

The new roots frequently emerged in rows, showing a relationship between their point of emergence and the leaf traces. How far is the position of the root, its form and shape, governed by the constraining resistance of the older lignified tissue experienced by the rapidly expanding tube of internal callus? Can the adventitious root so formed be regarded as parenchyma, moulded into cylindrical shape?

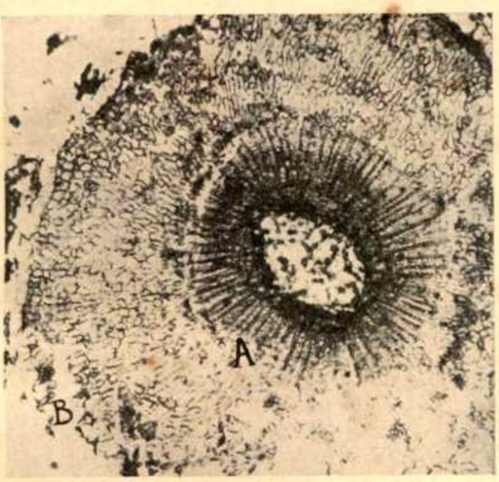

Fig. 3.

Myrtus communis. *A* TO *B* SHOWING THE DEVELOPMENT OF PARENCHYMA IN A REGION WITHOUT ROOTS. ×40 DIAMETERS. OTHER DETAILS AS FIG. 2.

Whilst the cambium may be stimulated at different seasons, including the period of natural quiescence, and whilst root formation may also be induced at various times of the year, the response obtained from one species differs in quality and degree with the season at which treatment is applied and with the co-related nature of the material so selected.

It is difficult to refrain from the attractive speculation that the natural seasonal excitation of the cambium results from the downward translocation of similar substances, formed from young leaves the veins of which are directly connected to the outer portion of the wood. Diffusion to, and excitation of, the cambium could readily take place, as shown by the morphological studies made by Priestley[3] using the 'strip method'.

I thank Miss W. Hopwood for cutting and preparing sections and Messrs. N. K. Gould and F. C. Brown for the photomicrographic illustrations.

Isolation of Carotene from a Wood-Oil

THE intensive studies of the past few years have illustrated the wide distribution of the carotenoids in Nature, but so far as we are aware, the occurrence of this group of pigments in the oils extractable from timber has not been recorded.

Acacia acuminata, which possesses an extraordinarily hard and heavy stem, is indigenous to Western Australia where, owing to its marked resistivity to termites, it has been extensively used for fencing and similar purposes where this property is of importance. The timber, locally known as 'jam' wood, has a pronounced odour, reminiscent of the common raspberry, *Rubus indæus*, and this persists in the timber for years, and in the wood-oil obtained by extraction with light petroleum. A suggestion that carotene might be present in the dark red oil was made by Hill[1]. It is now confirmed by our isolation of the pigment by chromatographic fractionation on alumina.

The adsorption experiment was carried out on the oil, as preliminary analyses had indicated a very small content of saponifiable matter. A number of coloured zones, indicating the presence of at least six carotenoid pigments, were observed. From one of these an extract was obtained which gave 21 mgm. of crystalline β-carotene, m.p. 178°. The amount present in the oil is probably considerably greater than this yield of 0·21 per cent. Dr. R. A. Morton very kindly carried out a spectroscopic examination of the other carotenoid fractions, but reported that they were not pure enough for spectrographic differentiation and identification. Fifty per cent of a non-odoriferous highly fluorescing oil is unadsorbed by the alumina. This is probably hydrocarbon in character. It is likely that the odour of the timber results from a breakdown of carotenoids to β-ionone, of which it is reminiscent.

No opinion can yet be offered as to whether the high carotenoid content is in any way related to the resistance of the wood towards termites.

Phospholipid Synthesis during Fat Absorption

WE have recently reported some experiments on the distribution and on the rate of 'organification' of phosphorus in rat's tissues[1]. With the same radioactive technique we have now investigated the synthesis of phospholipids during the absorption of large quantities of fat.

A rat weighing about 250 gm. was fed on 5 gm. of olive oil and 7·5 mgm. of radioactive sodium phosphate having an activity of 1,600 of our radioactive units (R.U.). Nine hours later the rat was bled. The absorption of the ingested phosphate was very complete, as no more than 42 R.U. was found in the gastro-intestinal tube and in the fæces.

The tissues were extracted with alcohol and alcohol plus ether and the extracts purified with anhydrous chloroform. The phospholipids of the liver and gut were further precipitated by acetone plus magnesium chloride. The acetone precipitate of the liver has been finally fractionated with cold alcohol. We call the soluble fraction 'lecithin' and the insoluble one 'cephalin', though we are well aware that the separation is by no means a complete one.

The phosphorus of the extracts and their fractions was mineralized and titrated by the Neumann-Machebœuf procedure. Finally, the phosphorus was reprecipitated as phosphomolybdate and the radioactivity measured. The results are reported in the accompanying table.

Tissue		Weight of moist tissue (gm.)	Lipidic P (mgm.)	Radioactive P (R.U.)			Specific activity
				in the whole tissue	per gram of moist tissue	per cent of the ingested P	
Liver	'Lecithin'	7·41	8·62	58·2 ± 1·0	7·9 ± 0·1	3·64	(7·1) 6·7 (6·4)
	'Cephalin'	,,	2·58	14·8 ± 0·9	2·0 ± 0·1	0·92	(5·1) 4·3 (3·6)
	Total Phospholipids	,,	11·20	73·0 ± 1·0	9·9 ± 0·1	4·56	(6·4) 6·0 (5·7)
Intestine		4·22	3·86	40·3 ± 0·5	9·6 ± 0·1	2·52	(10·7) 10·4 (10·1)
Kidney		2·39	2·80	8·2 ± 0·5	3·4 ± 0·2	0·51	(3·4) 2·9 (2·4)
Spleen		0·92	0·75	0·5 ± 0·6	0·6 ± 0·7	—	(3·0) 0·7 (−1·7)
Heart		0·89	0·92	0·0 ± 0·5	0·0 ± 0·6	—	(1·7) 0 (−1·7)
Skeletal muscle		5·49	2·72	0·3 ± 0·5	0·1 ± 0·1	—	(0·7) 0·1 (−0·4)
Blood corpuscles		2·39	0·25	0·0 ± 0·5	0·0 ± 0·2	—	(6) 0 (−6)
Blood plasma		2·61	0·07	0·5 ± 0·5	0·2 ± 0·2	—	(30) 7·5 (−15)

We give the weight of moist tissue, the weight of phosphorus, its radioactivity (in the whole lipidic extract and per gram of moist tissue, with the statistical error of the measurements) and its specific activity (with possible errors assuming a maximum and minimum value given by the mean value plus or minus three times the statistical error). Dividing the radioactivity by the total radioactivity of the sodium phosphate (1,600 units) one has the fraction of the ingested phosphorus which was found in each organ.

From the table it is apparent that, some hours after the ingestion of the fat and radioactive phosphorus, comparatively large quantities of ^{32}P were already found in the phospholipids of the liver ('lecithin' as well as 'cephalin') and of the gut. The absolute amount was larger in the liver, the content per gram of moist tissue being about the same in the two organs: 'specific activity' was higher in the intestine. Kidneys showed a small, but definite, activity. Heart, spleen and skeletal muscle showed practically no activity. The results for plasma and blood corpuscles are inconsistent, probably owing to the small content of phosphorus.

These findings should be compared with those communicated in our previous letter. Indeed in the experiment, in which ^{32}P was injected parenterally, the rate of phospholipid synthesis was found to be larger in liver, gut and kidney than in other tissues. Further, the rapid formation of phospholipids in liver and intestine during fat absorption is in agreement with many results reached by other methods. Our experiments show that the kidney is also involved in this process, which must be regarded not as a simple substitution of fatty acid radicals into the phospholipid molecule, but as a complete synthesis starting, at least partially, from inorganic phosphorus. We thank Prof. E. O. Lawrence and the Radiation Laboratory of the University of California for their most generous gift of ^{32}P.

Relation of the Adrenal Cortex to Cyclical Changes in the Female Accessory Reproductive Organs

IN a recent communication[1] one of us recorded the fact that periodic uterine bleeding still occurred in a spayed monkey that was being injected daily with a constant threshold dose of œstrone. It was suggested that this phenomenon is due either to the periodic liberation of some other hormone that raises the uterine threshold to œstrogenic stimulation, or to some undefined inherent periodicity in the responsiveness of the uterus to œstrone. Further consideration of the problem leads us to believe that the adrenal cortex may be responsible both for the persistence of uterine cycles under these conditions and for variations in uterine sensitivity. Our reasons for this suggestion are as follows:

(1) The hormones of the ovary and the adrenal cortex are related in chemical structure, and both organs are controlled by the anterior lobe of the pituitary. It has been shown in many species of vertebrate that the weight of the adrenal cortex fluctuates in accordance with changes in reproductive condition. Thus Anderson and Kennedy[2] found that the adrenal cortex of the rat undergoes alterations in size and lipoid staining response during the œstrous cycle. The weight increases until œstrus occurs, when ovulation takes place, and then decreases to the initial level, these changes being repeated in each successive œstrous cycle. A similar increase in the weight of the adrenal cortex at the time of ovulation has been shown to occur in frogs[3] and pigeons[4].

(2) It is well established that at least one of the principles of the adrenal cortex is intimately concerned with the regulation of the water and salt balance of the organism. This is shown by the fact that removal of the adrenals is followed by considerable excretion of sodium chloride and by diuresis. Conversely, Thorn *et al.*[5] have found that the injection of cortical extract into normal individuals causes a temporary retention of intravenously injected sodium chloride.

(3) The menstrual cycle in monkeys is related to well-marked changes in water-metabolism. Krohn and Zuckerman[6] and Fisher and Zuckerman[7] have observed that water is retained in the sexual skin of the macaque and baboon during the first half of the menstrual cycle, and that considerable diuresis occurs when the sexual skin swelling subsides.

(4) Œstrous cycles generally cease after adrenalectomy. It has, however, been found by Kutz *et al.*[8] that œstrus occurs at normal intervals in adrenalectomized rats if the life and health of the animals are maintained by the administration of salt.

This last observation suggests that the regular occurrence of cyclical changes in the uterus is dependent on a normal water-metabolism. It would also seem that at least part of the mechanism underlying the fluctuations in water and salt metabolism of the female macaque and baboon during the menstrual cycle is the coincident cycle in the activity of the adrenal cortex, the secretion of which fluctuates as does that of the ovary in response to cyclical alterations in the activity of the anterior lobe of the pituitary. It is probable that cyclical alterations in adrenal cortical activity still persist in spayed monkeys, and that the consequent hydration and dehydration of the accessory reproductive organs is the factor that is responsible for variations in the responsiveness of these organs to a constant dose-level of œstrone.

Effect of Progesterone on Lactation in the Rat

DRUMMOND-ROBINSON and Asdell[1] showed that ablation of the corpora lutea in the pregnant goat caused milk secretion provided the operation was done after the development of the mammary lobule-alveolar system. This suggests that the corpus luteum inhibits lactation prior to parturition, though the work of Anselmino *et al.*[2,3] indicates that the inhibitor is different from the hormone which causes proliferation of the uterine endometrium. On the other hand, Frei and Grüter[4] reported that injections of suspensions of corpus luteum tissue exerted a favourable effect on lactation in the cow. The experiments reported briefly below confirm the contention of Anselmino *et al.*, since we have found that administration of relatively high doses of pure progesterone to the lactating rat does not inhibit lactation as judged by the rate of growth of sucklings.

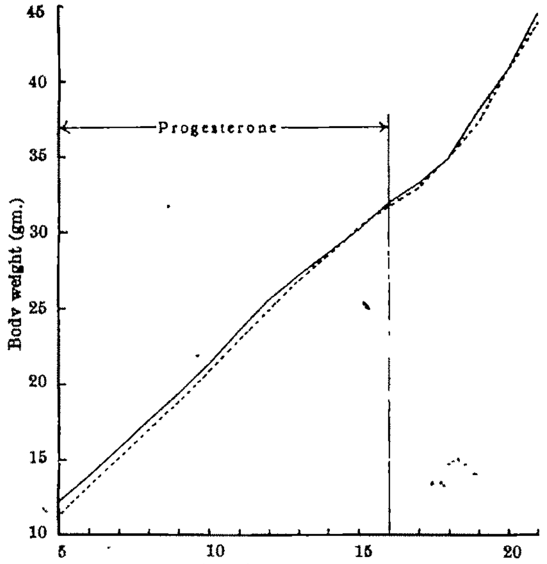

Fig. 1.

AVERAGE GROWTH-RATE OF POOLED LITTERS. FULL LINE, MOTHERS INJECTED DAILY WITH 1 MGM. PROGESTERONE IN 0·2 ML. ARACHIS OIL. DOTTED LINE, MOTHERS INJECTED DAILY WITH 0·2 ML. SESAME OIL.

Two groups of four lactating rats were used, one experimental and one control. Litters larger than eight were reduced to that number, as is the standard practice in this laboratory. In the case of two of the control rats, the litters numbered seven and six respectively. One litter in each group suffered reduction by the death of a female during the experiment. Each experimental rat was given twelve daily intramuscular injections of 1 mgm. crystalline semi-synthetic progesterone dissolved in 0·2 ml. arachis oil beginning on the fifth day *post partum*. Total number of young in litters was 17 males and 15 females; average gain in weight of mothers from parturition to weaning, 21 gm. Owing to an error, the controls were given similar injections, not of arachis oil but of sesame oil, but it is extremely unlikely that this would affect the outcome. Total number of young in litters was 14 males and 15 females; average gain in weight of mothers from parturition to weaning, 23 gm. We are greatly indebted to Dr. A. N. Macbeth and Messrs. Organon Laboratories Ltd. for the gift of the progesterone used in this work.

The average growth-rates, from the fifth day *post partum* to weaning, of all the young of each of the two groups of rats are plotted in Fig. 1. It will be seen that there is no difference between the mean growth-rates for the two groups of sucklings, which shows that progesterone, at the relatively high dosage given, neither inhibits established lactation in the rat, nor causes any increase in milk secretion.

Wettability of the Cellulose Walls of the Mesophyll in the Leaf

THE moisture regain curves (sorption isotherms) of cellulose show a steep rise at high relative humidity, but the water content at saturation (about 18 per cent of the dry weight of raw cotton) is definite both for natural and for regenerated celluloses[1]. To explain why no loosely adhering liquid condenses even when ample time is allowed for dispersal of the heat generated, it is sometimes suggested that the vapour, even under the best controlled experimental conditions, is never fully saturated. This view is, however, difficult to reconcile with the definiteness and reproducibility of the saturation maxima, especially as the regain curves are here so very steep. That these curves have a finite and not an infinite slope at saturation suggests another explanation, namely, that a clean cellulose surface may be incompletely wettable by water.

The unwettability of natural cotton is generally ascribed to the existence of a film of wax or oil covering its outer surface. Masson[2], who directed attention to the marked rise of temperature which the dried material shows on immersion in water, attributed this thermal effect to the condensation of water which has diffused as *vapour* across an air film which remains clinging to the waxy surface. In passing, we may remark that this view appears to us to require some slight modification, for it has been found that the bulk of the water neither gains nor loses heat until conduction from the cotton comes into play[3].

It seemed to us worth while to study the wettability of other natural cellulose surfaces, such as those which surround the cells in the mesophyll of plant leaves. Strips of leaf, cut so as to permit free exit of air at the top and entry of liquid at the bottom, were placed vertically with their lower edges in contact with water. Capillary rise was in no case observed, and it was found impossible to produce the entry of water into the mesophyll air-space system without either a pressure gradient or prolonged immersion. On the other hand, organic liquids such as benzene, chloroform, ether and essential oils, infiltrate rapidly into the mesophyll air-space by capillarity; vertical strips several centimetres long become completely filled in a very short time although the surface tensions of all these liquids are much less than that of water. Medicinal paraffin shows the same result and on account of its non-toxic character is suitable for comparative experiments with water. The results of many similar experiments show that, whilst all the other liquids named enter the capillary air-space system against gravity, water will not do so.

Leaves infiltrated with water by pressure gradient were found, on exposure to bright sunlight, to clear the mesophyll interspaces of liquid in a period of about two hours. Observed by transmitted sunlight under slight magnification, the retreat of the water appears to be a markedly discontinuous process, the water receding suddenly from areas several millimetres broad, and then halting for a time.

All the above experiments have been carried out with the leaves of *Ficus elastica*, which on account of their architecture are very suitable for this purpose. Moreover, by tearing the blade of this leaf it is possible to expose the mesophyll over an area of several centimetres, and the action of different liquids when placed on the exposed surface can then be followed under the microscope. A drop of water so placed remains supported on the summits of the mesophyll cells and does not flow down and fill the air-spaces. If now a drop of oil be placed at the end of the strip, the oil can be seen to enter the capillary system instantly and advance through the interspaces. Arriving at the drop of water, the oil enters the mesophyll spaces lying under the water, displacing the air, and presently emerging on the far side until the whole strip appears oily. Watched under a magnification of 100 (without a cover glass), the oil when applied can be seen to rush into the capillary spaces in an advancing wave which is followed at a short distance by the main wave of oil, so that in less than a minute a strip 2 cm. long becomes completely covered. When a drop of water is allowed to remain on the surface of the mesophyll, any part of the drop in contact with the surface of the fine vascular bundles flows out along the bundles, but does not spread laterally over the mesophyll cell-walls.

It is clear from these observations that the surfaces of the mesophyll have but the smallest adhesion to water, but that the outer tissues of the fine lateral veins have a much higher adhesion energy. It then becomes necessary to reconsider the conditions obtaining at the interface where transpiration takes place, for the above observations entirely negative the view that transpiration occurs from a liquid film of water on the cell walls of the mesophyll.

Determination of Aneurin (= Vitamin B$_1$) in Urine by the Thiochrome Method

WE have now worked out Jansen's method[1] for the determination of aneurin for the estimation of this vitamin in urine. Most difficulties were overcome by diluting the urine by about three times its volume of water, by working entirely in a nitrogen atmosphere and by substracting the fluorescence of a franconite eluate to which no potassium ferricyanide had been added from the fluorescences of some eluates which

A Method for Determining Ice-Water Relationships by Measurements of Dielectric Constant Changes

A NEW method for studying freezing points of soils has been developed by us[1]. Freezing point depressions of soils with water contents covering almost the entire growth range of plants have been measured.

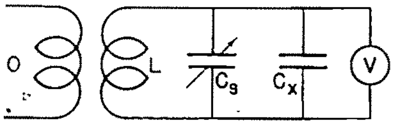

Fig. 1.

The method depends upon the measurement of capacitance changes of an electrical condenser, the metallic conducting plates of which are permanently attached to the walls of a glass vessel containing the material to be studied. The capacitance of such a condenser is a function of the dielectric constant of the water contained in the material. In the liquid state, water has a dielectric constant of approximately 80. After freezing, the dielectric constant of the ice formed is approximately 4. This magnitude of difference obtains if alternating current of sufficiently high frequency is used in making the capacitance measurements. Frequencies of the order of those used in the radio broadcast range are desirable; in these experiments 1,800 kilocycles per second was used.

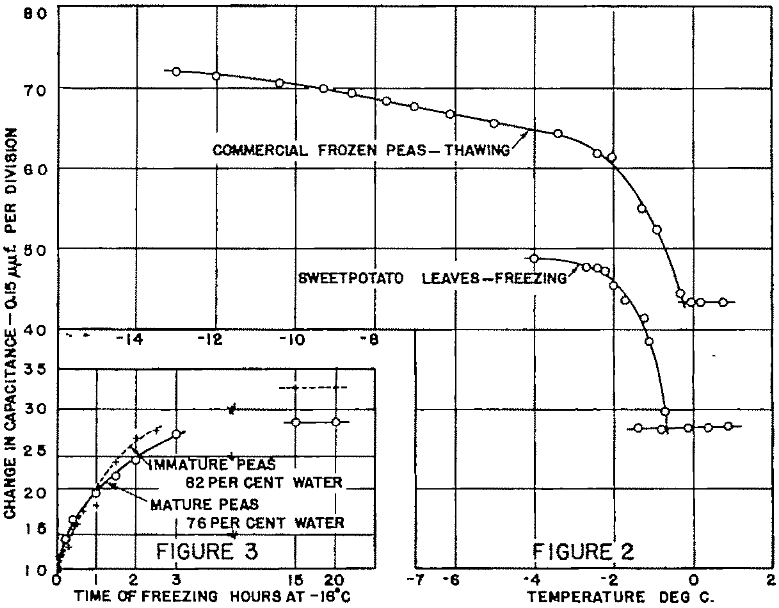
Fig. 1 is a schematic diagram of the circuit used in measuring the capacitance of the condenser containing the material; *O* is an oscillator which emits radio frequency waves at a frequency of 1,800 k.c./sec.; *L*, C_s, and C_x form a receiving circuit which may be tuned to the oscillator frequency. V is a vacuum tube voltmeter which indicates a maximum when the receiving circuit is tuned to resonance with the oscillator. C_x is the condenser containing the material and C_s is a calibrated variable condenser.

Resonance between the two circuits is obtained for a definite value of capacitance supplied by C_s and C_x. Any decrease occurring in the capacitance C_x, such as takes place if the water in the material freezes, may be compensated by an increase in the capacitance C_s. Thus, by determining the capacitance of C_s necessary to tune the circuit to resonance with the oscillator, one can determine any change in capacitance of the condenser containing the material (C_x).

Due to the great change in dielectric constant of water when it freezes, a curve of capacitance versus temperature of the condenser containing the material shows a marked change in direction at the temperature where ice begins to form. Thus, it is possible to determine the freezing or melting point of materials, containing, other than water, only constituents the dielectric constants of which show no sharp change with variation in temperature.

The temperature of the material studied may be maintained at a given value as long as is necessary for establishing thermal equilibrium. If this is done, the curve obtained consists of a number of equilibrium values. Hence the freezing-point which is obtained from such a curve should be an equilibrium value. It has been recognized that freezing point determinations on colloidal materials by the widely used Beckmann technique are not equilibrium values, and hence their use is questionable where equilibrium conditions are assumed, such as in the calculation of vapour pressures.

This method for determining freezing points has been applied to some plant materials. An example of the kind of data obtained is shown in Fig. 2. The curve for sweet potato leaves is for freezing, while that for frozen-pack commercial green peas is for melting. Supercooling is clearly shown on the sweet potato leaf curve. It is, however, possible to obtain the freezing point accurately, since by the graphic method it is not necessary to obtain data exactly at the point of initial ice formation.



If one assumes that the dielectric constants of the materials present in the condenser, other than water, do not change significantly over the temperature range studied, the following interpretations may be made. When the curve is parallel to the temperature axis, no water is being frozen or melted with change in temperature. When the curve is vertical with respect to the temperature axis, pure water is being frozen or melted. When the curve is inclined to the temperature axis, ice is being separated from or melted into a solution, as in the concentration or dilution of a sugar solution. This latter effect may also be brought about by capillary forces or by colloidal substances the avidity of which for water varies with their concentration.

Fig. 3 shows the results obtained upon freezing fresh green peas using time as a variable instead of temperature. 19 gm. of green peas at room temperature were placed in the condenser and immersed in a thermostat held at −16° C. At the time of immersion and at intervals thereafter capacitance measurements were made. The time required for complete freezing is the time elapsed before the capacitance reaches a constant value. The curves shown are for mature and immature peas taken from the same lot. Since the condenser containing the peas was surrounded by an air jacket, it is possible that the rate of heat transfer was the limiting factor in the earlier part of the freezing time. The method offers the opportunity of determining when such substances are completely frozen throughout. It should be noted that the peas with the higher moisture content showed a greater capacitance change upon freezing. Possibly with improved technique, quantitative interpretation of the relation between capacitance change and the amount of ice formed may be made.

This method is being presented here in the hope that it may prove useful in fields outside those with which we are concerned. The data presented in this paper were obtained with the first apparatus built and are to be regarded only as representative of the type of results obtainable. The functions of the laboratory do not permit the following up of this problem from any except the soil point of view. It seems very probable that the method would be useful in studying the winter hardiness of plants, the freezing injury to fruits and vegetables, and storage temperature for meats. It may also be useful in preparation of frozen-pack foods.

Radioactive Isotopes of Copper

In view of the fact that copper has only two stable isotopes $^{63}_{29}$Cu and $^{65}_{29}$Cu, it is difficult to account for the large number of different half-life periods reported for radioactive copper isotopes. Of the two short periods of 6 min. and 10·5 min., the latter has been satisfactorily attributed to $^{62}_{29}$Cu[1,3,4]. Periods of 6h. and 10h. have been obtained by neutron bombardment[1,5] and a 12·8h. period given by deuteron bombardment[2,8]. Since this latter product emits both positrons and electrons, there is good evidence for labelling it $^{64}_{29}$Cu. A radioactive copper has been chemically separated from zinc bombarded by fast neutrons, of half-life variously reported at 6h. and 10h.[1,5,6]. Madsen has directed attention to the confusion over these periods and gives the half-life period of the copper obtained from zinc as 17h.[7].

Leo Szilard, of the Clarendon Laboratory, Oxford, informed us that the decay curve of the copper bombarded by fast neutrons from radon-beryllium contained a period of a few hours which was absent when slow neutrons were used, or if the radioactive copper was obtained from zinc by fast neutron bombardment. It was arranged with him that further investigations and chemical separation should be made in this laboratory.

We irradiated 2 gm. mols of pure cupric oxide with fast neutrons from a 200 mc. radium-beryllium source. After irradiation, we dissolved the oxide, added 500 mgm. of nickel salt and precipitated the copper as cuprous iodide. The separated nickel after purification and conversion to nickel sulphide, showed an activity of 80 impulses/min., 1½ hours after irradiation had ceased, decaying with a half-life of 160 ± 10 min. We found the same half-life period in nickel irradiated by slow neutrons, in agreement with Rotblat, Naidu and Heyn[9]. It must be due to a radioactive isotope $^{63}_{28}$Ni or $^{65}_{28}$Ni, and may be produced either from $^{63}_{29}$Cu or $^{65}_{29}$Cu by capture of a neutron and expulsion of a proton.

We found that copper irradiated with slow neutrons in the absence of fast neutrons showed an activity of half-life 13 ± 0·5h. and that the same half-life period was obtained by separating radioactive copper from zinc bombarded by fast neutrons. In these experiments the initial activities were about 300 impulses/min. with a background of 20 impulses/min.

This radioactive copper may well be identical with that produced by bombarding copper by deuterons and is accordingly likely to be $^{64}_{29}$Cu. The 6 min. period of copper obtained by slow neutron capture would then be due to $^{66}_{29}$Cu.

No indication of a 6h., 10h. or 17h. period was obtained in our experiments.

Thanks are due to the Department of Scientific and Industrial Research for a grant and to Imperial Chemical Industries, Ltd., for the purchase of apparatus.

Artificial Radioactivity produced by Fast Neutrons and their Inelastic Collisions

Several investigators have reported that fast neutrons give rise to a transformation of an irradiated element in which the newly formed nucleus results from the original nucleus through the loss of a neutron[1,2].

I have made some experiments on the activation of copper, zinc and silver by fast neutrons. As the efficiency in these cases is small, I used the following arrangement: A foil of the metal under investigation, measuring 8 cm. × 5 cm., was wrapped around the source (50 mc. radon + beryllium) in the form of a spiral, so that the effective solid angle was equal to $4 \times 4\pi$. After activation, the foil was given the form of cylinder of 24 mm. diameter, which fitted the Geiger counter. In this way I obtained an activity which was four times larger than with the usual arrangement. In the case of copper, I found in accordance with Heyn[2] a radio-element of 11 min. half-period, produced by fast neutrons only. An element of this period was found by Bothe and Gentner[3] by irradiation of copper with very hard γ-rays, so that our product must be ^{62}Cu derived from ^{63}Cu by loss of a neutron. The initial activity due to the 11 min. body is about one half the initial activity due to the 5 min. body.

In the case of zinc, I was able to confirm the existence of the 60 min. half-period product. Miss Nuswald, working in this laboratory, has found that this element is an isotope of nickel and not of zinc as stated by Heyn.

In the case of silver, Guében[4] has reported the formation of a 50 sec. activity which possibly could be attributed to fast neutrons only. I have investigated the activitation of silver and found no trace of the 50 sec. product. In the course of these experiments, however, I obtained a definite proof of the existence of a product of 25±3 min. half-period which does not appear after irradiation with slow neutrons. It seems very likely that this product is identical which the 24 min. element obtained by Bothe and Gentner, so that we have almost certainly the reaction

$$^{107}Ag + n^1 = {}^{106}Ag + 2n^1$$

The efficiency of this reaction is about 0·03 of the total efficiency of fast neutrons in producing radioactivity in silver.

In the type of activation studied in this communication, the kinetic energy of the colliding neutron is nearly completely converted into the excess of mass of the system formed, so that after the collision both the colliding and the extracted neutron must have a very small kinetic energy, and therefore be much more efficient than the fast neutrons in producing activation of the 'capture' type. This phenomenon may account, at least partially, for the increase of artificial activity observed when fast neutrons pass through relatively small thicknesses of certain absorbing substances, and attributed hitherto to inelastic collisions[5]. Some rough calculations based on the values of cross-sections of fast neutrons for different types of activation lead to results which are in agreement with the experiments.

I am very much indebted to Dr. H. Herszfinkiel for many valuable suggestions in the course of this work.

Raman Spectrum of Monodeuteroethylene

MONODEUTEROETHYLENE has been prepared (J.C.J.) in two different ways. Starting from vinylbromide and deuterium bromide, obtained by the action of deuterium oxide on redistilled phosphorus pentabromide, the monodeuteroethylenebromide was prepared. This compound was submitted to the action of zinc and yielded monodeuteroethylene. Several spectra of the liquid compound were taken at a temperature of − 140° C.; the lines are listed in the accompanying table. The strongest lines of ethylene also appeared.

The monodeutero compound has also been obtained mixed with more highly substituted ethylenes by exchange of deuterium oxide and ethylene on a nickel catalyst at 80° C. (Polanyi).

Using a potential function for the ethylene molecule determined by Manneback and Verleysen[1] in their work on di- and tetradeuteroethylenes, the nine plane vibration frequencies of the unsymmetrical monodeuteroethylene have been computed (G.L. and Y.L.T.). The difficulty of expanding a determinant equation of the ninth degree and finding its roots was reduced materially by using suitable methods of calculation.

	C_2H_4 (calc.)	C_2H_3D (calc.)	C_2H_3D (obs.)	C_2D_4 (calc.)
1	949·7	789·2	—	678·1
2	950·0	947·5	—	758·3
3	1343·9	1268·2	(6) 1284·2	1008·9
4	1444·0	1387·3	(5) 1395·7	1072·8
5	1621·3	1578·7	(10) 1599·1	1428·8
6	2988·0	2266·2	(1·5) 2266·3	2152·5
7	3019·0	3001·8	(2) 2963·2	2288·9
8	3069·0	3045·9	(9) 3015·0	2308·0
9	3107·0	3092·5	(0·5) 3104·8	2325·0

The intensities are derived from photometric measurements. These results are expressed in cm.$^{-1}$. They show that the differences between calculated and observed data are less than 1·5 per cent. For comparison, the frequencies of C_2H_4 and C_2D_4 are given as calculated[1] by means of the same potential function. The difference between the calculated values for C_2H_4 and the experimental values from which the potential function was obtained are always less than 0·15 per cent.

The modes of vibration have also been computed. They suggest interesting qualitative remarks concerning the intensities and polarizations that may be expected in the Raman and in the infra-red spectrum. All vibration frequencies of C_2H_3D should, of course, be active in both spectra. Roughly speaking, a mode of vibration of the molecule C_2H_3D resembles very much the one or two modes of the symmetrical molecule C_2H_4 or C_2D_4 the frequencies of which lie nearest its own. For example, ν_8 in C_2H_3D is very weak in the Raman effect and nearly antisymmetrical with respect to the carbon axis, as would be inferred from its position between ν_8, antisymmetrical, Raman active but weak, and ν_9, inactive in the Raman spectrum of C_2H_4. The motion of ν_5 of C_2H_3D is almost perfectly symmetrical with respect to the carbon axis; hence that line is found to be very strong and should be polarized in the Raman spectrum. On the other hand, the modes 1 and 2 in the symmetrical molecule are respectively inactive and extremely weak in the Raman effect; this explains why the two lines of lowest frequency could not be observed. The mode 6 is an averaging of the four modes 6, 7, 8, 9 of C_2D_4.

In the case of C_2H_3D, three more lines should appear in the Raman spectrum below 900 cm.$^{-1}$; they are due to motions out of the plane of the molecule. For the symmetrical molecule C_2H_4, two of these modes are Raman inactive; the third one has not yet been observed.

A more extended account of the work is in course of publication in the *Annales de la Société Scientifique de Bruxelles*. The experimental work has been carried out in the laboratory of Prof. M. de Hemptinne.

Force Constants and Molecular Structures

WE have examined the infra-red absorption spectrum of phosgene vapour. The following fundamental modes have been assigned: $A_1 : \omega_1 = 1827$, $\omega_2 = 578$, $\omega_3 = 300$; $B_1 : \omega_4 = 845$, $\omega_5 = c.300$; $B_2 : \omega_6 = 444$ cm.$^{-1}$., the allocation being in agreement with the recent polarization measurement of Ananthakrishnan[1].

The persistence of molecular constants throughout various radicals has been remarked many times: Linnett and Thompson[2] have proposed using values of the force constants in C_2Cl_4 when compared with those of CCl_4 and C_2H_4 to determine the extent of contribution from resonating structures in the first molecule. The difficulty in obtaining even semi-quantitative measurements in such cases lies in the uncertainty as to what any particular force constant implies: thus for CCl_4 the values for the CCl force constant in the literature range from 1·74 to 3·85 ($\times 10^5$ dynes/cm.) according to the force field used, while Linnett and Thompson introduce another estimate of 4·38. One must hesitate in utilizing force constants derived from not necessarily comparable force fields, especially when the molecules have different symmetry.

The force constants for the ethylenic linkage in C_2H_4 and C_2Cl_4 given by these authors are respectively 9·0 and 5·8: if a correction is applied to the Badger relation so that it may hold for a carbon-carbon link, the first represents the true ethylenic distance of 1·37 A., while the second gives 1·45 A. or a 75 per cent single bond effect! Actually, even the refined methods of electron diffraction can scarcely distinguish between the supposed interatomic distances of 1·37 A. and 1.38 A.; consequently any great difference between the two force constants is illusory. The divergence may arise from the use of too artificial a force field, and also because the calculations employed are rigorously applicable only to infinitesimal amplitude frequencies.

We have met with rather more success in the treatment of the similar molecules phosgene, formaldehyde and urea. The carbonyl force constants are of the order of 12·3, 11·5 and 10·2 respectively: and we may safely regard the carbonyl frequency, ω_1, for HCHO (1,744 cm.$^{-1}$) as the normal value. Hence the latter arises from a pure double bond; urea ($\omega_1 = 1{,}655$ cm.$^{-1}$) has a considerable single bond contribution, but phosgene in accordance with the very high value $\omega_1 = 1{,}827$ cm.$^{-1}$ has a marked triple bond effect arising from such structures as  rather than the single bond nature postulated by Pauling, Brockway, and Beach[3] and deriving from  The interatomic distances obtained by these authors for $COCl_2$ are CO = normal (?) = 1·28, and CCl = 1·68 < normal = 1·76; the original results of Dornte[4] (CO = 1·15 < normal, CCl = 1·80 A. > normal) are qualitatively more in agreement with the spectroscopic observations, while the chemical evidence is altogether in favour of the interpretation of phosgene as an acid chloride and not as a halogenated ethylene.

Measurement of Pressures in the Upper Atmosphere

IN the course of a series of photographs of the spectrum of the auroral afterglow in pure nitrogen at pressures varying from about 1 mm. to 0·01 mm., it was observed that the ratio of the intensity of the first-negative system of bands to that of the second-positive system changed gradually as the pressure changed. The first negative bands, which are emitted by the molecule ion, increased in intensity until, at the lowest pressure at which it was possible to photograph the afterglow, the spectrum consisted almost entirely of bands due to the ionized molecule.

This result suggests the possibility of measuring accurately pressures in the upper atmosphere of the earth, by simultaneous observations of the ratio of these two band systems in an auroral display and of the height of the aurora. A comparison of these results with those obtained in the laboratory should then give the pressure. A series of careful experiments is now in progress to determine the effect of a small quantity of oxygen on the intensity ratio of these two band systems and also to study the effect of tube size on this ratio. In view of the present results, auroral observers may be led to make observations of the intensity ratio of these band systems as well as of the heights of the displays.

Permeability of Metals to Hydrogen

IT is well known that all the common metals are permeable to hydrogen at high temperatures. The accompanying table brings out the rather remarkable fact that, at 1,000° C., the permeability of the metals for which data are available only varies by a factor of about 10.

RATE OF DIFFUSION OF HYDROGEN IN C.C. PER CM^2. PER. SEC. AT 760 MM. PRESSURE FOR 1 MM. THICKNESS OF METAL.

Metal	1,000° C	500° C	0° C.
Iron	1×10^{-3}	1×10^{-4}	6×10^{-8}
Nickel	2×10^{-3}	3×10^{-6}	1×10^{-11}
Molybdenum	4×10^{-3}	5×10^{-6}	2×10^{-10}
Platinum	1×10^{-4}	1×10^{-8}	5×10^{-15}
Copper	1×10^{-4}	1×10^{-8}	4×10^{-15}
Aluminium	—	2×10^{-7}	2×10^{-22}

Since, however, the temperature coefficient of diffusion varies considerably for the different metals, the rates of diffusion at low temperatures are very different. In the table the rates of diffusion at 0° C. have been calculated by means of the usual diffusion equation, and it will be seen that the rates for copper and platinum, for example, are now 10^9 times less than that for iron.

Iron is, in fact, by far the most permeable of these metals at room temperature. Apparatus for work at high pressures is usually made of steel to provide the necessary strength. The diffusion of hydrogen cannot be greatly reduced by increasing the thickness, since the rate of diffusion only varies directly as the thickness. A far more effective method of avoiding trouble from this cause would appear to be to line the steel vessel with a thin layer of one of the less permeable metals, such as copper or nickel. Provided this is free from porosity, 1 mm. of copper would be as effective as 5 miles of steel, and 1 mm. of aluminium would be better than 10^{13} miles of palladium!

Points from Foregoing Letters

PHOTOMICROGRAPHS of transverse sections of *Ceanothus dentatus* and *Myrthus communis*, showing the formation of cambium after treatment of cuttings with growth substance (alpha-naphthalene acetic acid) are submitted by Dr. M. A. H. Tincker. Similar stimulation of growth and formation of roots was observed in cuttings of *Viburnum Carlesii* after treatment with beta-indolyl acetic acid. The author suggests that the natural seasonal excitation of the cambium may result from the downward movement of similar substances formed in young leaves.

The presence of beta-carotene (a substance related to vitamin A) in the wood oil extracted from *Acacia acuminata*, a tree of Western Australia, is reported by Dr. V. M. Trikojus and Prof. J. C. Drummond.

By feeding a rat with olive oil to which radioactive phosphate had been added, and afterwards analysing its tissues, a group of investigators from the University of Palermo have found a large percentage of the radioactive phosphorus in the phospholipids (both the 'lecithin' and the 'cephalin' type) of the liver and of the gut. Kidneys also showed a small but definite activity, while the heart, spleen and skeletal muscle showed practically none.

Prof. C. N. H. Long and Dr. S. Zuckerman bring forward various considerations which lead them to the view that cyclical alterations in adrenal cortical activity still persist in spayed monkeys and are responsible for the periodic bleeding that can be induced by a constant threshold dose of œstrone injected daily.

Dr. S. J. Folley and Dr. S. K. Kon find that relatively high doses of the sex hormone, progesterone, when given to the lactating rat, do not inhibit lactation as judged by the rate of growth of sucklings. This, they consider, supports Anselmino's view that the inhibitor of lactation is a different hormone.

Prof. D. H. Bangham and Prof. F. J. Lewis show that whilst water adheres but weakly to the mesophyll cell walls in the leaf, organic liquids adhere strongly and rapidly fill the interspaces, under the influence of capillarity. On the other hand, water wets comparatively easily the outer surfaces of the fine vascular bundles of the leaf. It is concluded that the water vapour of transpiration is not evaporated from a film of liquid water, however thin, on the outer surface of the mesophyll cells.

A new method of studying the freezing points of soil and plant material is described by L. P. Alexander and T. M. Shaw and exemplified by results obtained with peas and sweet potatoes. It depends upon the great change in dielectric constant of water when it freezes, and is applicable whenever the dielectric constants of the materials present, other than water, do not change significantly over the temperature range studied.

By irradiating cupric oxide with fast neutrons from radium-beryllium, Dr. E. A. Oeser and J. L. Tuck have obtained a radioactive body of half-life 160 min. This precipitates with nickel and the authors consider it to be radioactive nickel of mass 63 or 65, produced from copper by capture of a neutron and expulsion of a proton. The authors direct attention to the large number of different half-life periods reported for radioactive copper isotopes and suggest their probable origin.

J. Rotblat has confirmed the existence of the 11 min. radio-isotope of copper, the production of which by fast neutrons was reported by Heyn. He has also found that fast neutrons give in silver the isotope of 25±3 min., probably ^{106}Ag. In both cases the new product is formed with emission of a nuclear neutron. An elementary process of this type leads to the appearance of two relatively slow neutrons which are more efficient than the primary neutrons in producing artificial radioactivity. This effect may account for the increase of radioactivity produced by fast neutrons after passage through some absorbing substances.

It is suggested by Prof. J. Kaplan that the variation in the relative intensity of bands emitted by the neutral molecule ion and those emitted by the neutral molecule in the auroral afterglow, might be used as the basis for a method of obtaining pressures in the earth's upper atmosphere, by comparing this ratio in actual auroras and in the auroral afterglow.

Research Items

Human Skeletal Material from British Honduras

Owing to the humidity of the soil, little human skeletal material has been recovered from Mayan sites in British Honduras. Skulls, jaws and long bones excavated by J. Eric Thompson at San José in 1931 and 1934 have been measured and described by Mr. Wilfrid D. Hambly, who also compares them with measurements of the living Maya of Yucatan and skeletal material from Baking Pot (*Anthropological Series*, Field Museum, Chicago, 25, 1). Study of the head-form is based on three skulls and three calvaria, each of which yielded some reliable measurements, though only in two were they numerous. The first is that of a child with a cranial capacity of 1,128 c.c. and a cephalic index of 91. A slight ante-mortem occipital flattening has led to some distortion. The second skull, in the strongly developed occipital protuberances and development of the glabella and supra-orbital ridges, shows male characteristics. There is slight occipital flattening, though it is doubtful whether this is artificial. The third is a male less rounded than other specimens. Considerable ante-mortem loss of teeth had taken place; there is caries with much signs of wear. In this specimen the facial index can be calculated as 79·1, comparable with a mean index on fifty living Maya males (Steggerda) of 82·46. The fourth skull is the only one which gives the measurements necessary for the dental index, 45·2, bringing the specimen just within the macrodont class. The calvarium, of an aged male, yields an index of 95·2, but there is some distortion. A second calvarium, which shows considerable occipital flattening, has an index of 91·0. The left half of a calvarium has a very pronounced occipital protuberance and its length of 183 mm. is so far in excess of other length measurements as to indicate that it is an aberrant form. Comparative measurements are as follows:

		Length	Breadth	Index	Capacity in c.c.
San José	♂	156·0	139·2	87·6	1260
Baking Pot	♂	173·6	146·0	84·3	1375
	♀	163·2	144·0	88·4	1225
Maya (living)	♂	180·41	153·71	85·01	
	♀	170·57	148·79	87·11	

Snowshoes

A study of snowshoes, which is the outgrowth of an interest in crude bearpaw snowshoes used on occasion by the Grand Lake Victoria Indians of western Quebec, has led Mr. Daniel Sutherland Davidson to some interesting and somewhat surprising conclusions, which have a bearing on general principles of ethnographical observation and the interpretation of geographical distributions (*Mem. Amer. Phil. Soc.*, Philadelphia, 6; 1937). The snowshoe, one of the most important aboriginal inventions in the northern hemisphere, apparently has contributed directly or indirectly to the great expansion of northern peoples and has encouraged man to invade and to reside permanently in regions inland which previously had discouraged occupation. The snowshoe, in concept, appears only to have been invented once. Its distribution is contiguous, but various peoples have changed and elaborated the original form. The wooden snowshoe, in plank form originally, possibly was brought into America by a proto-Algonkian migration and afterwards diffused to the Caribou Eskimo, who still retain it in its original form. In the Old World the frame shoe appears not to have modified the wooden shoe at all, but rather the reverse. In the New World the wooden shoe never evolved, its modifications being due to adoption from the frame shoe; but in the Old World the wooden shoe changed by modifications inherent in the shoe itself. The bearpaw shoe appears to have originated in Asia, and to have diffused westward to Europe and to have been brought to America by migrating Athabascans, it may be making possible their great expansion.

Migration of Sea-Trout

A marking experiment, in which 196 sea-trout smolts were marked in 1933, and 1,798 in 1934, has been carried out in the Wisloka, a tributary of the Vistula, and the results are now described by St. Żarnecki (*Bull. Intern. Acad. Polon. Sci. Lett.*, 8, 449; 1936). The place of liberation was a long distance from the sea and it was hoped that this would give more definite information about several features of the migration. The number of recaptures was low compared with Scottish recoveries in similar experiments, 3 of the first lot and 47 of the second; but it showed that the mean of the periods occupied in the migration from spawning places to the sea was about 5 months and 3 weeks (173·3 days), and that the rate of travel averaged 5·8 km. in the 24 hours. Most interesting perhaps was the fact that the recaptures in the sea showed that the initial direction of the migration of young sea-trout was eastward of the Vistula estuary. This direction corresponds with the flow of the Vistula waters, which where they debouch in the Baltic Sea, run eastward almost parallel to the coast. Whether this be simply due to the fact that the sea-trout having followed the current for so long continue to do so, or to some kind of selection, it affords the migrants a short period of accommodation for the change from fresh-water to sea-water environment.

Respiration in Locusts

Recent field experiments on the destruction of flights of locusts by the discharge of toxic dusts from an aeroplane raise various problems in connexion with respiration in these creatures. Dr. A. G. Hamilton now discusses (*Bull. Entom. Res.*, March 1937) the mechanism of respiration of locusts and its bearing upon the inhalation of poisonous dusts. Experiments made with flying locusts, suspended from threads in a wind tunnel and immersed in a cloud of finely particulate cuprous cyanide, are described. Several investigators have brought forward evidence showing that the first four spiracles are inspiratory in function and the remaining six are expiratory. There is, however, lack of adequate evidence whether the anterior spiracles also function in an expiratory manner and whether the remaining spiracles, or any of them, act as inspiratory apertures. In the present paper, confirmation is given to the belief that the first four spiracles are inspiratory organs, but their possible expiratory function has not been subject to investigation. As regards the remaining six pairs of spiracles, only the last or tenth spiracles were found to perform a double function, namely, expiratory in flying locusts and inspiratory when the insects are not in flight. The functions of the different spiracles were determined by the presence or absence of cupric cyanide in the associated tracheæ. By killing the locusts with hydrogen sulphide, the cuprous cyanide is converted into copper sulphide, and since this latter is black it is readily seen in the white tracheal tubes. Its presence implied that a particular pair of spiracles was inspiratory in function.

Interpretation of the Flower

UNDER this general title, Dr. Agnes Arber recently discussed some even more general questions of plant morphology (*Biol. Rev.*, 12, 1937). Goethe's conception that the flower is equivalent to an abbreviated vegetative shoot is handled very sympathetically, and in particular a very good case is made for the thesis that was thoroughly worked out by de Candolle, that the carpel has its equivalence with an infolded foliar organ. A recent opponent of this theory (Grégoire) has complained that nowhere can be found a full and reasoned statement of this thesis, and Mrs. Arber supplies a most convincing brief exposition of the salient features of this analogy between leaf and carpel. She does much more, however, for she points out the result of the impact upon morphological discussions of the evolutionary and phylogenetic atmosphere in which this discussion has continued since the publication of the "Origin". As the result, 'equivalence' has had a new meaning read into it; in the course of phylogenetic history a leaf is assumed to have become a carpel, and Grégoire would reject the foliar theory because in development a carpel does not arise from a foliar primordium. This restatement of the Candollean hypothesis and its separation from the phylogenetic atmosphere, in which it cannot have its original meaning, is a valuable service to morphology, but perhaps even more valuable for the English reader is the clear statement of the aim of the *Gestalt* morphology of Troll, which is introducing yet a new concept into pure morphological speculation and refuses either to base itself on phylogeny or upon teleological 'adaptive' interpretation. This new morphology is not less interesting because it sees the flower, or the inflorescence that simulates the flower, as the expression of a 'flower type', the significance of which is, as yet, quite elusive.

Hybrid Vigour in *Sorghum*

THE cultivated sorghums all belong to the species *Sorghum vulgare* and are classified into four types, grain, forage, grass and broomcorn types, which have the same chromosome number and are fully interfertile. Messrs. R. E. Karper and J. R. Quinby (*J. Hered.*, 28, No. 3) find that the F_1 hybrids between different types show a degree of hybrid vigour which in some cases is quite remarkable and differs for each cross. The cross between Hegari sorghum and dwarf broomcorn yielded an F_1 more than two and one half times as tall as the parents and producing nearly three times as much forage and grain. In certain crosses the plants were 15 feet tall and yielded 150 bushels of grain per acre. Milo and Hegari always produced extreme vigour and lateness in their hybrids, other varieties producing vigour without lateness. Heterosis is also shown by increased size of endosperm, which is correlated with the vigour of the plant. The extreme vigour of hybrids of Milo and Hegari is attributed to the presence in them of many dominant genes for growth, other varieties having some of the corresponding recessives. In certain crosses there is an increase of yield unaccompanied by increased height or change in time of maturity. Bulk emasculation of the flowers was carried out by means of hot water.

Erysiphaceæ of Japan

YASU HOMMA has recently published a very extensive monograph on the powdery mildew fungi (Erysiphaceæ) of Japan (*J. Fac. Agr. Hokkaido Imp. Univ., Sapporo, Japan*, 38, Pt. 3, 183–461, Feb. 1937). The treatment is exhaustive, and there are two divisions, a general part and a systematic part. The general part deals with the structure, formation and germination of conidia, and the occurrence of fibrosin bodies therein, with the perithecia, their asci and ascospores, with hibernation, host-parasite relations, immunity and resistance. Much experimental work is reported in this section, and very extensive inoculations of the fungus *Erysiphe graminis* f. sp. *Tritici* upon a wide variety of wheat species are described. Germinating conidia of the fungus penetrated the epidermis of both immune and susceptible kinds of wheat, but no further development of the germ tube took place within an immune plant. Infection by conidia was effected most easily during the period of greatest vigour of growth of the host. The systematic part records nine species new to science, and Japan possesses one endemic genus in *Typhulochæta*. This is distinguished from all other genera of the Erysiphaceæ by the clavate appendages to the perithecium. Eight plates illustrate structural and taxonomic details, and the paper is fully indexed. It contains more than 180 citations of published work, and should provide a valuable book of reference for mycologists outside the territorial limits implied by its title.

Deafness and the Use of Hearing-Aids

A COMMITTEE of the Medical Research Council has issued a report upon the physiology of hearing, giving the results of investigations into the utility of hearing-aids to deaf people ("The Use of Hearing Aids", A. W. G. Ewing, L. R. Ewing and T. S. Littler, M.R.C. Special Rep. Series, No. 219. H.M.S.O. 9*d.* net). In recent years the assistance that can be given to the deaf has been greatly increased because the extent to which a patient is in need of a hearing-aid, and the kind of aid most suitable, can be ascertained by audiometer tests to a degree previously impossible. The general increase in intensity of sound is only one aspect of the problem, as deaf persons vary in the extent to which they are deaf to different pitches of the auditory range, the object of a hearing-aid being so to modify the sound as to bring it within the range of hearing which the individual retains. The threshold of audibility for speech may be reliably deduced from the thresholds for pure tones obtained with a pure-tone audiometer or beat-tone oscillator. In general, it is within 5–10 decibels of the patient's lowest reading for pure tones over the frequency range 250–4,000 vib. per sec.

Of 158 adults tested, 94 obtained considerable help from a portable valve aid, 18 from non-valve battery aids, 2 from bone-conduction battery aids, 16 from speaking tubes only, and 28 were too deaf to derive help from any aid. Even when the most efficient type of aid is used, proficiency in lip-reading is also required if deafness is to be alleviated to the fullest extent. For teaching groups of deaf children, the class amplifier, into the microphone of which the teacher speaks, has advantages over individual aids.

Ultra-violet Light in the Upper Atmosphere

The spectrum of the sun, observed through the lower atmosphere, is cut off at about λ 2900 by an ozone layer which probably lies between 20 km. and 50 km. from the earth's surfaces. Phenomena which take place above this layer, such as the night-sky luminosity and the production of ionized layers, depend largely on the ultra-violet rays of shorter wave-length than this. M. N. Saha (*Proc. Roy. Soc.*, A, **160**, 155) reviews the action of such light on oxygen and nitrogen. The 'negative' bands of nitrogen, due to N_2^+, have been found in the light of the sky for a short time at sunrise and sunset, and these bands are supposed to be excited by light of wave-length less than λ 660. The intensity of this process indicates that the sunlight intensity at this wave-length is far larger than could be expected from a black body at 6,500° K.—a model which has often been used to represent the sun. The absorption of short wave-length ultra-violet light by oxygen and nitrogen has not yet been sufficiently investigated in the laboratory, but a number of possible processes are examined in the paper.

Nuclear Reactions in the Stars

The old suggestion of Eddington, that the building up of heavier elements from hydrogen goes on in the stars with continuous production of energy, has several times been examined in the light of modern information about nuclear reactions. C. F. v. Weizsäcker (*Phys. Z.*, 38, 176) has developed this idea in some detail. The nuclear velocities resulting from temperature in the interior of a star are high enough for nuclear reactions of the lightest elements to take place with fairly high probability. These reactions involve both the building-up and breaking-down of nuclei, so that the light nuclei undergo cycles of transformation. Neutrons are produced and are held responsible for the building of the heavy elements. The reactions between light nuclei take place in very deep regions where the density is low on account of radiation pressure. A small part only of the star's mass takes place in rapid cyclic processes, but fresh supplies of light atoms are brought into the active region by convection. The stability of a star against radial pulsations is due, it is suggested, to the damping effect of a time-delayed β-transformation which is a link in the cycle. This effect fails for very slow pulsations, and in fact Cepheid variables of period larger than a certain value are not known. The life-history of a typical star is sketched. In a pure hydrogen star, the first process is the reaction of a proton and an electron to form a neutron: this is endothermic and requires a very high temperature. The cyclic charges begin and the star expands explosively. The star then settles down to a career of slow expansion, which lasts until its hydrogen supply is used up.

Axial Flow Fans and Pumps

In the preparation of "Data for the Design of Axial Flow Fans and Pumps" (London: The Draughtsman Publishing Co., Ltd. 2*s*.), Mr. R. Poole has taken as granted the principles and theory of his subject and has confined himself to an exposition of the means and methods by which the actual determination of the design is effected. In the space at his disposal it is possible to deal with only one aerofoil shape—he has chosen Glauert's extended Joukowski aerofoil—but it must be understood that the method is not inappropriate in other cases. This impeller is shaped like aeroplane wings and, therefore, the aerodynamical characteristics of the blades being known, the total pressure and torque on them can be ascertained taking into account their helicoidal path in relation to the fluid. For the theory and research on which the work is based references are made to papers and to Reports and Memoranda of the Aeronautical Research Committee, so that any reader who finds the notes insufficient for his purpose may refer to the usual sources. In design of this nature, the work largely depends on the determination of the appropriate constants and coefficients, and on the application of the relations between such characteristics as lift and drag, velocity, torque, thrust, interference, etc., which have been evolved and ascertained in the course of extended research, and can be expressed and arranged for use most conveniently in the form of diagrams and tables. Almost wholly, then, this pamphlet consists of the curves from which, stage by stage, the required design can be worked out. Only in so far as it is necessary to explain these curves and their purpose does the author employ letterpress, except at the end, where an example of the design of an axial flow fan in conformity with given requirements is fully worked out.

Filter Attachment to Portable Air Velocity Meter

Reference was made in Nature of June 27, 1936 (p. 1078) to a convenient portable air velocity meter, the 'Alnor velometer', put on the market by Messrs. Air Conditioning and Engineering, Ltd., 4–12 Palmer Street, London, S.W.1. New filter attachments have now been developed for use with this instrument when taking direct air velocity measurements in an atmosphere heavily laden with dust. By the use of a conversion chart, it is possible to use the same instrument with the filter removed.

Measurement of Photographic Plates by Projection

Mr. G. F. Kellaway has published a paper with this title (*J. Brit. Astro. Assoc.*, 47, 5, April 1937), in which he describes a method for projecting an enlarged image of the negative of a celestial body, by means of a projection lantern lens, on to a graduated screen, such as graph paper. Mr. Kellaway uses a Zeiss triplet of about 28 inches focal length to secure the negative, which is then projected on a screen. Two examples are given, one to determine the position of a star and the other of Whipple's Comet, both results being very satisfactory when compared with the catalogued position of the star or with visual observation of the comet. It is suggested that the method should be used when the object is faint and diffused, and those who possess small-scale cameras could increase their scope of work by spending a few shillings on a projection lens.

after-shocks; all these features pointing to a complicated origin covering a large area.

(5) Burma, divided into three main structural units—the Shan plateau (A, Fig. 2), consisting of rocks of Mesozoic and older ages, the Tertiary basin of the Irrawaddy valley (B), and the range of the Arakan Yoma of late Mesozoic and early Tertiary times (C). They are separated by zones of faulting, with which many of the epicentres of Burmese earthquakes are associated, especially those of the destructive earthquakes of 1839 and 1858, the former near Mandalay and the latter near Thayetmyo and Prome. During the years 1929-31, there was a remarkable series of eight earthquakes, the epicentres of which, numbered in the order of occurrence in Fig. 2, are marked by a linear arrangement close to the eastern fault.

Most of the Indian earthquakes of the last forty years have been investigated by officers of the Geological Survey of India, yet it must be admitted that the state of seismological research in the country is behind that in some other lands. In Japan there are a hundred and five seismological observatories, in the United States forty-two, but in India only six, and not one official devoted entirely to seismological subjects. Mr. West suggests that the work done more or less independently by the Geological Survey, the Meteorological Department and the Survey of India should be co-ordinated and expanded by founding what would practically be an Earthquake Research Institute with its headquarters, say, at Shillong, provided with many new instruments for stations new and old, and with officers who, after a great earthquake, should at once proceed to the central area and establish round it a network of temporary stations in order to determine the epicentres and focal depths of the after-shocks. C. D.

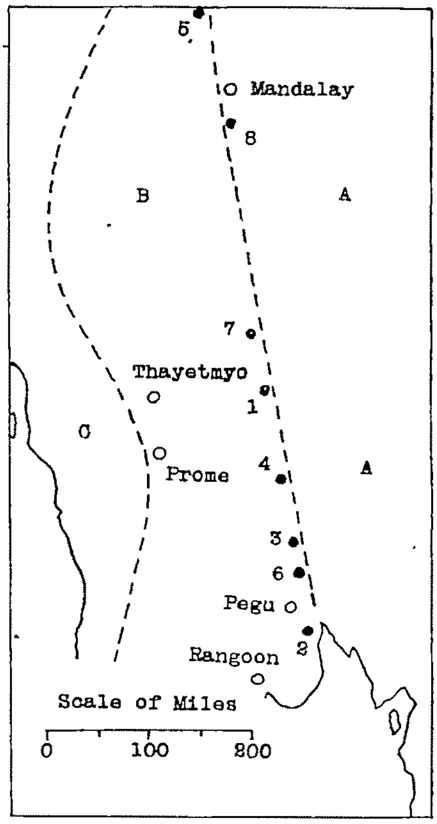

Fig. 2.
DISTRIBUTION OF EARTHQUAKES IN BURMA.

Incidence and Causes of Stammering

STAMMERING is one of those abnormalities sufferers from which fall between two stools. It is scarcely the concern of the family doctor, and yet is outside the scope of ordinary educational methods. Of recent years, psychological treatment has helped many individuals to cope with speech disabilities, but it commonly happens that more time and expense are called for in the achievement of a cure on these lines than stammerers are able to give, and so for one reason or another it usually falls to the lot of the individual stammerer to cure himself.

It is with special reference to some interesting figures supplied by the Stammerers' Club of New South Wales* that this short commentary on an important subject is given; as the result of questionnaires sent out to the members this Club has elicited most interesting information.

Whilst in most instances of stammering there is actual physical disability of some kind, nevertheless, for the most part the trouble is to be found in a constitutional nervousness or sense of inferiority. From the statistics from New South Wales, it is noteworthy that although serious illness is actually credited with nine per cent in the list of causes, no definite physical disease is said to have any serious influence. The cause of stammering generally is attributed to such psychological causes as shock, imitation, fright and being bullied or laughed at. In all these, it is evident that individual nerve sensitiveness or feeling of inferiority is the chief underlying trouble. That this nerve weakness is often inborn seems to be emphasized by the fact that in no less that fifty-one per cent of the instances dealt with the stammerer began before the age of five years, and no less than ninety-three per cent experienced the onset before the age of ten. Granted that unfortunate conditions in upbringing produced such psychological disturbance as to impair capacity for normal speech, it certainly cannot be held that all these stammerers were born with strong nerves or the capacity for developing sound defences against the stresses of life.

As regards position in family, it does not seem to matter whether one is born early or late if one is to experience the disadvantage of stammering; it is true that there is the difference between thirty-eight per cent as regards 'elder' children and twenty-five per cent as to 'youngest', but as the 'intermediate'

* Stammering: its Cause and Cure. (The Handbook of the Stammerers' Club of New South Wales.) Pp. 72. (Sydney Stammerers' Club of N.S.W., n.d.)

members are put down as thirty-seven per cent there is really not much in it. In regard to reaction to school conditions this is said to have been 'good' in eighty-one per cent and in nineteen per cent 'bad', whereas it might well have been expected to be the other way round.

A further point of interest which comes out of these statistics of the N.S.W. Stammerers' Club is that seventy-six per cent stammerers were boys and twenty-four per cent girls; moreover, the serious influence of this disability in the case of the latter as regards life as a whole is suggested by the figures which tell us that at thirty years of age approximately seventy-three per cent of the boys had got married whilst only thirty-seven per cent of the girls had been equally successful.

Usually relief of stammering depends on the determination of the individual sufferer who will make use of certain rules of elocution and self-help such as are readily accessible from teachers and handbooks on the subject. Certainly the stammerer who sets out to cure his difficulty must attain three objects; namely, (1) confidence; (2) attainment of a new habit; (3) the maintenance of a restful state of mind and body. He must learn to relax. He mus learn to use a new voice with a timing slightly br definitely different from that which he habituall uses when stammering. He can look forward cor fidently, if he determines to practice and to rely c himself, in any case he can perhaps take som comfort from remembering that he is one of a com pany of very famous men. Amongst kings one may remember that Louis II and Louis XIII of France are said to have stammered badly. Whilst at least one Queen of England (Mary II) was also troubled in the same way. I have always understood that Charles Lamb abandoned an intended career in the Church because of his speech disability, although stammering has not always been incompatible with a reputation as a famous speaker. Charles Kingsley, Phillips Brooks and Father Hugh Benson, all distinguished in the pulpit, are said to have stammered at times.

E. L. HOPEWELL-ASH

South-Eastern Union of Scientific Societies

ANNUAL CONGRESS AT HASTINGS

THE forty-second Congress of the South-Eastern Union of Scientific Societies was held at Hastings on June 8–12. The Mayor of Hastings, Alderman A. Blackman, welcomed a large gathering of representatives of affiliated societies and other members of the Union at the opening ceremony on June 8, when Prof. F. E. Weiss was installed as president of the Union for the ensuing year, and delivered his presidential address on "Competition and Co-operation in Nature".

In the past, competition in commerce and industry was regarded as beneficial to the community, but competition among industrialists is no longer in such great favour, and even in agriculture efforts are being made to restrict it. On the other hand, co-operation, which is the basis of communal organization, is not generally called in question. Prof. Weiss pointed out that these forces also exist in Nature. Darwin had pointed out that, owing to the enormous reproductive capacity of most plants and animals, a weeding out process is inevitable; there is a struggle for existence under which only the fit survive. Many plants produce hundreds of thousands of seeds, but do not appreciably increase in numbers on an area already covered with vegetation. In the case of plants, the struggle for light is often the dominant factor. There is also competition for the necessary food among animals, and the larger and stronger animals have an advantage over the smaller and weaker ones. In the case of carnivorous animals, however, the race is not always to the strong, but also largely to the swift and agile. Though the dictum "Nature red in tooth and claw" causes some people to regard evolution as a continuous competitive warfare in which might is always triumphant, Darwin pointed out that there are certain instinctive characters in many animals which make for the preservation of the race as a whole and as apart from the individuals, and that probably in these the basis of our moral nature had its beginnings. Parental instincts play a very important part in the survival of the more highly developed animals; there is here no competition fo food between parents and offspring, but, on th contrary, parents will often starve themselves for th benefit of their young. Prof. Weiss then dealt wit numerous cases of symbiosis, the classical examp in plants being found in lichens. He took two amples to illustrate competition and co-operat among plants, the rosette-forming plants of g lands illustrating competition, and plants of Leguminoseæ with their nodules carrying nitrify bacteria exemplifying co-operation.

"Our Changing Flora" was the theme of an addr delivered by Dr. R. W. Butcher to the Botanic Section of the Union. Man has brought abo remarkable changes in the flora of Great Britai The draining of fens, the turning of heathland int forest, rivulets made into canals, the digging of rai way cuttings and making embankments have al played an important part in bringing about changes There never has been, and probably never will be anything static about the flora. The ecologis recognizes a continual change of vegetation as basic principle in plant succession. Captain Dive has directed attention to rapid topographical changes in the South Haven peninsula of Dorset since 1700. Large masses of *Isoetes echinospora* are now found on the bed of Littlesea, yet this plant was unknown there a few years ago. Pearsall has recorded many changes in the vegetation of the English Lakes these changes being in accord with changes in th nature of the lake bottoms.

Mr. L. F. Salzman gave a paper on "The Writi of Local History" to members of the Archæologic

Section. He likened a local history to a large-scale map, for, he said, it is possible to indicate on such a map features which cannot be shown on a map portraying a whole country. In a local history it is thus possible to emphasize the human side of history.

To the same section Alderman T. S. Dymond read a paper on "The Cinque Ports Barons returned to Parliament, 1366 to 1722". Though the "Return of Members of Parliament", ordered by the House of Commons to be printed in 1878, began with the year 1290, the names of representatives from the Cinque Ports date from 1366 only. From that year until 1844, two members sat for Hastings. Before Queen Elizabeth's time, a representative from the free barons of the Port was chosen. Down to the great Reform Bill, freemen, elected by the bailiff (mayor) and jurats, alone had the franchise; by 1831 their number had fallen to twenty-three. At the election following the Reform Bill, Mr. North (father of Miss North, famous for the collection of Nature paintings in the North Gallery in Kew Gardens) was elected by 356 votes. In contrast with this number, 20,955 votes were cast for the successful candidate at the last election.

"Fossils in their Original Environment" was the subject of a lecture given by Dr. H. Dighton Thomas to the Geological Section. Dealing first with Trilobites, Dr. Dighton Thomas said that the loss of eyes in these organisms was co-related with their burrowing habits; the Welsh beds were deposited in deep water, and in them the Trilobites show a reduction in the development of eyes, and one of them was blind. Brachiopods were common in shallow water after the Devonian period. Changes in the fauna of deposits were brought about by changing conditions of salinity in the water. He does not regard chalk as a foraminiferal limestone, but as a Foraminifera-bearing limestone. The bulk of the chalk is of shallow water origin, and its fauna is not a deep water one. He suggested the collection of fossils from differing horizons in the chalk and the determination of the fauna of the separate zones, as there is a lack of knowledge of the succession of the fauna in chalk in England. The flora and fauna of the London Clay are those of a tropical sea, and plants similar to those in it are still found in lowland tropical countries, Nipa swamps being cited.

Many interesting excursions to places of interest [illegible] d Hastings were made. At Ashburnham Place, [illegible] herine Ashburnham kindly allowed the King [illegible] relics to be inspected, and on the same [illegible] the sites of Sussex ironworks were visited. [illegible] ing of iron ore and the forging of wrought [illegible] these sites date from very early times, and [illegible] arried on at the site visited until about 1813, [illegible] ast of the ironworkers dying in a cottage close [illegible] n 1883. The geologists paid a visit to Crowhurst [illegible] arry, where faulting is very clearly seen, and one of the visitors picked up a scale, apparently from a turtle, with the markings on the back clearly defined. The natural gas bore at Heathfield Station was inspected. Visits were also paid to local churches and to Pett Level, where, owing to exceptionally low tide, the remains of the submerged forest were plainly visible.

At the annual representative assembly, it was [illegible] nounced that the 1938 Congress would be held at [illegible] rthing, under the presidency of Dr. Julian Huxley. [illegible] A. W. Farquharson, of Le Play House, 33 Gordon [illegible] re, London, was elected honorary general [illegible] tary.

Science News a Century Ago

A Spanish Manuscript on Tahiti

AMONG the donations presented to the Royal Geographical Society at its meeting on June 26, 1837, was a Spanish manuscript, being the "Diary of an Expedition to, and Residence upon the Island of Tahiti", by Maximo Rodriguez, written in 1774. Rodriguez had accompanied an expedition from Lima to Tahiti, and with three other persons had spent about thirteen months in the island. Cook had heard of the visit of the Spaniards and had written: "Will anything ever become known to the world of the proceedings of the Spaniards at this island?" After a lapse of sixty years the diary was placed in the hands of a captain in the Royal Navy and by him presented to the daughter of Rodriguez, who having heard that Captain FitzRoy was making inquiries for manuscripts sent it to him begging his acceptance of it, saying that "she felt sure it would be better placed in the hands of an Englishman, and more valued in England, than it ever could be, concealed from the world, and uncared for, in her library at Lima".

The Institution of Civil Engineers

IN a memorandum issued on July 1, 1837, from 1 Cannon Row, Westminster, the Council of the Institution of Civil Engineers directed attention to the following subjects for communications and for premiums, during the session of 1838: the nature and properties of steam; the warming and ventilation of public buildings; accounts and drawings of the Plymouth Breakwater; the rates, from actual experiments, of the velocity, load and power of locomotive engines on railways, first upon levels, second upon inclined planes; description and account of the principles of Huddart's rope-making machinery at Limehouse; the sewerage of Westminster, and drawings and accounts of the shield used at the Thames Tunnel.

A Peat-Compressing Press

THE *Mechanics' Magazine* of July 1, 1837, contained a description of an improved machine for compressing peat invented by the Right Hon. Lord Willoughby d'Eresby. The machine was an upright press at the bottom of which was a rectangular cast-iron box into which a rectangular piston could be forced downwards by means of a rack and pinion. The interior of the box was lined with vertical iron bars between which small spaces were left so that the water could escape as the peat was compressed. "I find", wrote the inventor, "that the machine answers perfectly on about half the sorts of peat usually consumed, that is to say, on those of a fibrous quality; and I am still carrying on the experiment on a large scale. The peat when compressed, has been used with perfect success, instead of coal, for the purpose of calcining lime, for the smith's forge as well as for ordinary fuel."

The Museums of Copenhagen

ON July 2, 1837, Lyell wrote from Copenhagen to one of his sisters: "In the time of Linnæus this city contained finer collections of shells, and finer works were published here by Chemnitz (12 vols.) and others, than in any country in Europe. It is not wonderful, therefore, that even now some of the Danes should be far ahead, and that as Prince Christian had a taste for natural history, he should have a splendid private collection, and that the curator of his museum (containing above 8,000 specimens of living shells), Dr. Beck, should be one of the two or three best conchologists in the world. But besides this, Copenhagen possesses in its different museums most of the identical shells which Linnæus described in the edition of his 'Systema Naturæ' published during his life; and here therefore alone, we can verify incontestably the species which he really described and named. As Lamarck and others have in very many cases mistaken the shells which Linnæus meant, great confusion has arisen, and it is here alone that this confusion can most readily be cleared up.

"I am going over with Beck an examination of all the fossil species identified by Deshayes with living shells, and it will probably lead to many modifications of my views, at least many of my details, also to many new views which I shall perhaps have to test at Paris before I return."

Edge's Pendulum for Ships

In 1837, the Society of Arts awarded a silver medal to Adolphus George Edge, a mate in the Royal Navy, for his invention of a pendulum for showing the inclination of a ship when under sail, which could be used for regulating the elevation or depression of the guns. It was tried with favourable results in the *Inconstant* and *Pique*, and at the end of June 1837 Rear-Admiral F. J. Maitland wrote to the Secretary of the Admiralty, from the *Victory* at Portsmouth, saying that as Edge's pendulum had shown its great superiority "to two other pendulums tried against it in the Portsmouth Yacht, I am desirous that my intended flag-ship the *Wellesley* should be supplied with it; and I request you to be pleased to obtain permission for one to be made for me in Portsmouth Yard". A example of the pendulum was placed in the repository of the Society of Arts.

The Endless Ladder

Under this title the *Gentleman's Magazine* for June 1837 gives the following description of what appears to be a prototype of the moving staircase. "A patent has recently been obtained for a most ingenious and useful machine adapted to mining and many other purposes, where the main object is to raise or lower weights or packages in constant succession. This simple but very effectual contrivance consists of an endless ladder, made either of chain or rope, which passes under and over two revolving drums or cylinders, mounted upon horizontal axes; one placed at the bottom, and the other at the top of a shaft or plane, to and from which the ladder is intended to reach. A continuous motion being given to either of the cylinders by the power of steam or animal force, the endless ropes or chains furnished with horizontal stairs like those of a common ladder are made to circulate over the revolving cylinders by which they are distended, so that one part of this endless ladder is continually ascending with a slow but uniform motion from the lowermost of the cylinders to the uppermost, whilst vice versa the other part of the ladder is descending to the lowermost in an uninterrupted circulation."

University Events

Birmingham.—The new A. E. Hills chemistry building is to be opened formally by the donor on July 7. The opening address is being given by Sir Frederick Gowland Hopkins.

Glasgow.—Prof. G. G. Henderson has presented to the University a valuable collection of books and reprints on chemistry, and also an interesting series of engravings and photographs.

The following candidates were awarded the degree of D.Sc. at the graduation ceremony held on June 16: J. Bell (thesis: "Heavy Water and the Structure of Crystalline Hydrates", with additional paper); J. D. Loudon (thesis: "The Cationoid Reactivity of Nitrodiphenylsulphones", with additional papers); Anne H. McAllister (thesis: "Clinical Studies in Speech Therapy").

Honorary degrees were conferred on the following, among others: *LL.D.*, Prof. J. Boeke, professor of histology and embryology, University of Utrecht; J. M. Cowan, physician, Glasgow; Prof. T. K. Monro, emeritus professor of medicine, University of Glasgow; Sir Robert Muir, emeritus professor of pathology, University of Glasgow; Sir Albert Seward, emeritus professor of botany, University of Cambridge; Prof. R. Stockman, emeritus professor of materia medica, University of Glasgow.

Liverpool.—On June 4, honorary degrees were conferred on the following, among others: *LL.D.*, Lord Leverhulme, formerly pro-chancellor of the University; Sir Hector Hetherington, principal and vice-chancellor of the University of Glasgow, formerly vice-chancellor of the University of Liverpool; *D.Sc.*, Prof. C. T. R. Wilson, formerly Jacksonian professor of natural philosophy, Cambridge; *D.Eng.*, Mr. A. P. M. Fleming, director and manager of the research and education departments of the Metropolitan-Vickers Electrical Co., Ltd.; *Litt. D.*, M. René Dussaud, Department of Syrian and Palestinian Antiquities, Louvre Museum.

Manchester.—In addition to the grant of £5,000, recently announced, in aid of the biochemical research directed by Prof. I. M. Heilbron, the Chemistry Department has now received from the Rockefeller Foundation a further grant of £300 a year for tw [illegible] years in aid of the application, under Prof [illegible] Polanyi, of physico-chemical methods to the [illegible] tion of problems of biological interest.

A chair of theoretical physics has been [illegible] in the University to which Prof. D. R. H [illegible] present Beyer professor of applied mathema [illegible] been appointed.

Dr. J. G. Woolham has been appointed hon [illegible] assistant lecturer in physiology. Dr. J. M. Jack [illegible] and Dr. J. A. Todd have resigned their posts in t [illegible] Department of Mathematics on appointment a [illegible] lecturers in Westfield College, University of London, and the University of Cambridge respectively.

Oxford.—At Encænia on June 23, honorary degrees were conferred upon the following, among others:—*D.C.L.*: The Right Hon. W. G. A. Ormsby-Gore, Hon. R. H. Brand and Sir Herbert Baker. *D.Sc.*: Prof. Walter Nernst. *D.Litt.*: Dr G. P. Gooch.

Prof. J. H. Hutton, of Cambridge, has b [illegible] appointed Frazer lecturer in social anthropo [illegible] for 1938.

Royal Society, June 17.

LORD RAYLEIGH : The surface layer of polished lica and glass, with further studies on optical con- ct. The reflecting power of a polished silica surface amined at normal incidence in a liquid having the me refractive index as the body of the material, ries widely according to the treatment. Surfaces lished by a process which removes material rapidly surfaces washed in dilute hydrofluoric acid, do t reflect appreciably in the liquid. Surfaces polished methods which do not quickly remove the material y reflect as much as 0·28 per cent of the incident ht. A kind of burnishing seems to take place, hich modifies the surface, and may bring up its fractive index from 1·461, the ordinary value, to much as 1·61, quite as high as light flint glass, d much higher than any known variety of silica. ese effects are found in a less degree in ordinary ass, and in a much less degree in crystal quartz. normal cases the reflected light changes in tint m red to blue as the refractive index of the mersion fluid is increased through the critical value r minimum reflexion. The modified silica surface anomalous in this respect, the reflexion being red either side of the minimum value. The explanation f this is discussed.

F. P. BOWDEN and T. P. HUGHES : Physical roperties of surfaces. (4) Polishing, surface flow, d the formation of the Beilby layer. The process f polishing is greatly influenced by the relative elting point of the polisher and the solid. If the lisher melts at a higher temperature than the solid, rface flow and polish of the solid will readily occur. the melting point of the polisher is below that of e specimen, surface flow takes place very slowly not at all. In general, the amount of surface flow governed, not by the properties of the polisher and ecimen at room temperature, but by their relative echanical properties at the high temperature of the ding surfaces. Experiment suggests that polish is ought about by an intense local heating of the rface irregularities to the melting or softening point. he molten or softened solid flows or is smeared over e surface, and rapidly solidifies to form the polished ilby layer.

D. J. MALAN and H. COLLENS : Progressive htning. (3) The fine structure of return lightning okes. The fine structure of return lightning strokes s been studied from the photographs of 120 flashes ken with Boys and other cameras. There are two pes of structure exhibited by branched and by branched strokes respectively. In the case of a anched stroke the time-luminosity curve at the base the stroke shows that when the first upward oving luminosity (component 1) reaches a branch- g point, the channel again increases in luminosity mponent 2), the luminosity falling off when the end the branch has been reached. Later components using a new increase in channel luminosity may our when further branching points are reached. These mponents are thus intimately connected with the anching processes. The components of unbranched rokes are never observed to start before the stroke s reached the cloud. All components associated ith branches are found to progress with velocities excess of 10^{10} cm./sec. Their direction is indeterminate. Components not associated with branches but with the cloud charge itself, progress either upwards or downwards, their velocities varying from 2×10^{8} cm./sec. to more than 10^{10} cm./sec. The low-velocity components are observed to progress downwards only. The total number of components observed at any point along the channel decreases after passing branching points, the highest number being observed at the base of the stroke. The time-intensity curve at the base of a stroke shows that the first two components are the most important. No evidence of components which can be ascribed to self-oscillation of the channel has been found.

Brussels

Royal Academy (*Bull. Classe Sci.*, 23, No. 2 ; 1937).

L. GODEAUX : An algebraic variety of three dimensions of bigenus one.

TH. DE DONDER and Y. DUPONT : New theory of the dynamics of continuous systems (5).

E. DE WILDEMAN : The number of carpels of the flowers of *Rubus caesius* L. and the number of the druplets of its fruits.

TH. DE DONDER : The uniqueness of the adjoint system of De Donder's linear partial differential equations.

D. FREYDENBERG : Note on numerical combinations with a constant sum.

P. BURNIAT : Projective models of canonical surfaces.

A. APPERT : Transitive topologies.

G. DUFRANE : A birational transformation of space having a given fundamental curve.

J. VAN MIEGHEM : Fundamental relation between the variations of pressure and temperature in the atmosphere.

J. L. DESTOUCHES : Minimal conditions which a physical theory must satisfy.

J. FAUTREZ : The athrocytosis of acid colouring matters. Stable and labile athrocytosis.

P. DENIS : A new alkaloid of the Rubiaceæ : rubradinine.

M. HOMÈS and G. VAN SCHOOR : The presence of certain growth-promoting substances in *Elodea canadensis*.

(*Bull. Classe Sci.*, 23, No. 3 ; 1937).

L. GODEAUX : Some algebraic varieties in three dimensions having canonical and pluricanonical surfaces of order zero.

G. HIRSCH : A generalization of a theorem of Borsuk, concerning certain transformations of the *analysis situs*.

O. ROZET : The nets of integral invariants.

S. DE BACKER : Viscous fluids and propagable waves (3).

P. SWINGS and A. GATHOYE : Note on the absolute magnitudes of *Be* and *B* type stars.

M. NICOLET : Theoretical determination of the effects of absolute magnitude of the molecular bands in stellar spectra.

J. EECKHOUT : Polarographic reduction potential of dinitro compounds.

D. CRESPIN and M. DESIRANT : New empirical formula for the spectroscopic determination of the internuclear distance of diatomic molecules.

L. LISON : Structure of the cryptosoleniated region in the Coleoptera *Tenebrio molitor* L. and *Dermestes lardarius* L.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Tuesday, June 29

Warburg Institute, at 5.30.—K. de B. Codrington: "Play and Ritual".*

Royal Anthropological Institute, at 8.30.—Annual General Meeting.

Dr. H. S. Harrison: "Ethnology under Glass" (Presidential Address).

University of Manchester, July 1–2.—Conference on "Magnetism" to be held in the Physics Department.*

Achema VIII.—Chemical Engineering Exhibition to be held at Frankfort-on-Main on July 2–11.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned.

Lecturer in Librarianship in the Municipal College, Romford Road, E 15—The Principal (June 28).

Lecturer in Geography in the Normal College, Bangor—The Principal (June 28).

Assistant Lecturer in Mathematics in University College, Cardiff—The Registrar (June 30).

Assistant Lecturer in Zoology in University College, Gower Street, London, W.C.1—The Secretary (July 1).

Research Biochemist at the Runwell Hospital, Nr. Wickford, Essex—The Physician Superintendent, envelope marked "Biochemist" (July 1).

Assistant Lecturer in Zoology (woman) in University College, Leicester—The Registrar (July 3).

Lecturer in Refractory Materials in the Royal College of Science—The Secretary, Imperial College of Science, Prince Consort Road, London, S.W.7 (July 3).

Lecturer in Mathematics in King Alfred's Training College, Winchester—The Principal (July 3).

Junior Scientific Officers in the Admiralty Scientific Pool (July 9: quote C.E. 4472/37) and Assistants (grade III) in the Admiralty Technical Pool (July 3. quote C.E. 4473/37)—The Secretary to the Admiralty (C E. Branch).

Assistant Lecturer in Agricultural Chemistry, Assistant Lecturer in Agricultural Zoology, Instructor in Poultry Husbandry and Instructors in Horticulture in the University of Leeds—The Registrar (July 5).

Demonstrator in Botany at University College, Southampton—The Registrar (July 5).

Assistant Analyst in the Borough of Southwark—The Town Clerk, Southwark Town Hall, Walworth Road, S.E.17, envelope marked "Assistant Analyst" (July 5).

Research Assistant in the Chemical and Animal Nutrition Research Division, Ministry of Agriculture, Northern Ireland—The Secretary, Civil Service Commission, Stormont, Belfast (July 6).

Assistant Lecturer in Anatomy in University College, Cardiff—The Registrar (July 7).

Adviser in Animal Husbandry in the Department of Agriculture, Malta—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S W 1 (July 7).

Principal of the County Technical College, Guildford—The Chief Education Officer, County Hall, Kingston-upon-Thames (July 10).

A Lecturer and an Assistant Lecturer in Botany in the University of Manchester—The Registrar (July 10).

Assistant Civil Engineers (male) in the Civil Engineer-in-Chief's Department, Admiralty, and H.M. Naval Establishments abroad—The Civil Engineer-in-Chief, Admiralty, London, S W 1, envelope marked "A.C.E." (July 12).

Head of the Mechanical Engineering Department at the Croydon Polytechnic—The Education Officer, Education Office, Katharine Street, Croydon (July 12).

Geologists on the Geological Survey of Great Britain—The Director of the Survey, Exhibition Road, London, S W.7 (July 31).

Ten Temporary Gazetted Civilian Engineers in the Military Engineer Services, India—The Under-Secretary of State, Military Department, India Office, envelopes marked "C E. Recruitment" (July 31).

Reid Lecturer in Anthropology in the University of Aberdeen—The Secretary (August 31).

Professor of Economics in the University of Adelaide—The Secretary, Universities Bureau of the British Empire, 88A, Gower Street, London, W.C.1.

Metallurgist (alloy steels) and Two Metallurgists in the Research and Development Department, The Mond Nickel Co., Ltd, Thames House, Millbank, S.W.1—The Manager.

Lecturer in Mathematics in the College of St. Mark and St. John, Chelsea—The Principal.

Lecturers in Economics, Electrical Installation and Engineering Science in the Kingston Technical College—The Principal.
